RAYNAL to SARREGUEMINES

RAYNAL, GUILLAUME THOMAS FRANÇOIS (1713–1796), French writer, was born at Saint Geniez, Rouergue, on April 12, 1713. He was educated at the Jesuit school of Pezenas, and received priest's orders, but he was dismissed for unexplained reasons from the parish of Saint-Sulpice, Paris, to which he was attached, and thenceforward he devoted himself to society and literature. The Abbé Raynal wrote for the *Mercur de France*, and compiled a series of popular but superficial works, which he published and sold himself. These—*L'Histoire du stathoudérat* (The Hague, 1747), *L'Histoire du parlement d'Angleterre* (London, 1748), *Anecdotes historiques* (Amsterdam, 3 vol., 1753–54)—gained for him access to the salons of Mme. Geoffrin, Helvétius, and the baron d'Holbach. He had the assistance of various members of the *philosophie coterie* in his most important work, *L'Histoire philosophique et politique des établissements et du commerce des Européens dans les deux Indes* (Amsterdam, 4 vol., 1770). Diderot indeed is credited with a third of this work, which was characterized by Voltaire as "du réchauffé avec de la déclamation." The other chief collaborators were Pechméja, Holbach, Paulze, the farmer-general of taxes, the Abbé Martin, and Alexandre Deleyre. The "philosophic" declamations constituted its chief interest for the general public, and its significance as a contribution to democratic propaganda. The *Histoire* went through many editions, being revised and augmented from time to time by Raynal; it was translated into the principal European languages, and appeared in various abridgments. Its introduction into France was forbidden in 1779; the book was burned by the public executioner, and an order was given for the arrest of the author, whose name had not appeared in the first edition, but was printed on the title page of the Geneva edition of 1780. Raynal escaped to Spa, and thence to Berlin, where he was coolly received by Frederick the Great, in spite of his connection with the *philosophie party*. At St. Petersburg he met with a more cordial reception from Catherine II, and in 1787 he was permitted to return to France, though not to Paris. He was elected by Marseilles to the states-general, but refused to sit on the score of age. Raynal now realized the impossibility of a peaceful revolution, and, in terror of the proceedings for which the writings of himself and his friends had prepared the way, he sent to the constitutional assembly

an address, which was read on May 31, 1791, deprecating the violence of its reforms. This address is said by Sainte-Beuve (*Nouveaux lundis*, xi) to have been composed chiefly by Clermont Tonnerre and Pierre V. Malouet, and it was regarded, even by moderate men, as ill-timed. The published *Lettre de l'abbé Raynal à l'Assemblée nationale* (Dec. 10, 1790) was really the work of the comte de Guibert. During the Terror Raynal lived in retirement at Passy and at Monthéry. On the establishment of the Directory in 1795 he became a member of the Institute of France. He died in the next year on March 6, at Chaillot.

See A. Feugère, *Un Précurseur de la Révolution: L'abbé Raynal* (1921).

RAYNALD OF CHÂTILLON (d. 1187), a knight in the service of Constance, princess of Antioch, whom she chose for her husband in 1153, four years after the death of her first husband, Raymond (*q.v.*). One of Raynald's first acts was a brutal assault on the patriarch of Antioch; while two years later he made an unjustifiable attack on Cyprus, in the course of which the island was ravaged. The act brought its punishment in 1159, when he had to humiliate himself before the emperor Manuel, doing homage and promising to accept a Greek patriarch; and when Manuel came to Antioch in the same year, and was visited there by Baldwin III, Raynald led his horse into the city. Later in the year he was captured by the Mohammedans, during a plundering raid against the Syrian and Armenian peasants of the neighbourhood of Marash, and confined at Aleppo. His captivity lasted 17 years. Released in 1176, he married Stephanie, the widow of Humphrey of Toron, and heiress of Krak and Mont Royal, to the southeast of the Dead Sea—fortresses which controlled the trade routes between Egypt and Damascus, and gave him access to the Red Sea. In Nov. 1177, at the head of the army of the kingdom, he won a victory over Saladin, who only escaped with difficulty from the pursuit. But in 1181 the temptation of the caravans which passed by his fortress proved too strong, and in spite of a truce between Saladin and Baldwin IV he began to plunder. Saladin demanded reparations from Baldwin IV. Baldwin could only reply that he was unable to coerce his unruly vassal. The result was a new outbreak of war between Saladin and the Latin kingdom (1182). In the course of the hostilities Raynald launched ships on the Red Sea, partly for buccaneering, partly, it seems, with the design of attacking Mecca, and of challenging Mohammedanism in its own

holy place. His ships were captured by one of Saladin's officers; and at the end of the year Saladin himself attacked Raynald in his fortress of Krak, at a time when a number of guests were assembled to celebrate the marriage of his stepson, Humphrey of Toron. The siege was raised, however, by Count Raymond of Tripoli; and till 1186 Raynald was quiet. In that year he espoused the cause of Sibylla and Guy de Lusignan against Count Raymond, and his influence contributed to the recognition of Guy as king of Jerusalem. His policy at this crisis was not conceived in the best interests of the kingdom; and a step which he took at the end of the year was positively fatal. Hearing of a rich caravan, in which the sister of Saladin was travelling, he swooped down from his fortress upon it. Thus for the second time, he broke a truce between the kingdom and Saladin. Guy could not extort from him the satisfaction which Saladin demanded: Raynald replied that he was lord in his lands, and that he had no peace with Saladin to respect. Saladin swore that Raynald should perish if ever he took him prisoner; and next year he was able to fulfil his oath. He invaded the kingdom, and, at the battle of Hittin, Raynald along with King Guy and many others fell into his hands. They were brought to his tent; and Saladin, after rebuking Raynald strongly for his treachery, offered him his life if he would become a Mohammedan. He refused, and Saladin either slew him with his own hands or caused him to be slain (for accounts differ) in the presence of his companions.

The death of Raynald caused him to be regarded as a martyr; his life shows him to have been only a brigand of great capacity. He is the apotheosis of the feudal liberty which the barons of the Holy Land vindicated for themselves; and he shows, in his reckless brigandage, the worst side of his character. Stevenson, *Crusades in the East* (Cambridge, 1907), takes a most favourable view of Raynald's career: cf. especially pp. 240-241. But his whole life seems to indicate a self-willed and selfish temper.

RAYNAUD'S DISEASE, a malady first described by P. Edouard Raynaud in 1862 in a paper on "Local Asphyxia and Symmetrical Gangrene of the Extremities." It is a disease of childhood or early adult life, and females are more frequently affected than males. Raynaud attributed the symptoms to an arrest of the passage of blood to the affected parts, and considered this caused by a spasm of the arterioles. That the skin capillaries in the various stages correspond with this view has been shown by G. E. Brown but the more fundamental aetiology is unknown. If the spasm be sufficiently prolonged and intense to close completely the arterial channels, gangrene of the part may result.

The local symptoms are divided into three well-marked stages. The first is *local syncope*, in which the affected parts become temporarily bloodless, white, cold and anaesthetic. The condition is familiar in what is termed a "dead finger," and is usually bilateral. After a variable time the circulation may become restored with a tingling sensation, or the disease may progress to the second stage, that of *local asphyxia*. In this condition some part of the body, usually a finger, toe or the whole hand or foot, becomes painful, bluish-purple or mottled, and cold. The discoloration may deepen until the skin is almost black, the tactile sense being lost. After several hours, the attack may pass off. Such attacks of local asphyxia may return every day for a time. Sometimes severe abdominal pain is present, accompanied by haematuria. In the third stage, that of *local gangrene*, the involved areas assume a black and shrivelled appearance, livid streaks marking the course of the arteries; blebs may form containing bloody fluid. The degree of destruction varies from the detachment of a patch of soft tissue down to the loss of even a whole limb, the part becoming separated by a line of demarcation as in senile gangrene.

In Raynaud's disease the patients have been noticed to be very susceptible to cold; the extremities must be kept warm; and the activity of the circulation roused by douches and exercise; by these means an attack may be prevented. Should local asphyxia have taken place, one of the best treatments to lessen pain and obtain the return of the natural colour is the application of the constant current, the limb being placed in a bath of warm salt and water. Cushing's method of inducing active hyperaemia has been attended with much success. This treatment is only applicable

when the vascular spasm affects the extremities, and consists in the artificial constriction of the limb by the application of a tourniquet or Eschsch's bandage for a few minutes daily. This is followed by hyperaemia and increased surface temperature, and affords much relief to the pain of the stage of asphyxia. Drugs which dilate the peripheral vessels, such as amyl nitrite and trinitrine, have also been recommended. The disease tends toward recovery with more or less loss of tissue if the stage of gangrene has been reached.

See G. E. Brown, *Arch. Int. Med.*, 1925, XXXV, 56.

RAYNOUARD, FRANÇOIS JUSTE MARIE (1761-1836), French dramatist and *savant*, was born at Brignoles (Provence), on Sept. 8, 1761. He was educated for the bar and practised at Dragunagan. In 1791 he went to Paris as deputy to the legislative assembly, but after the fall of the Girondists, he was imprisoned in Paris. During his imprisonment he wrote his play *Caton d'Utique* (1794). *Les États de Blois* and *Les Templiers* were accepted by the Comédie Française. *Les Templiers* was produced in 1805, and, in spite of the protests of Geoffroy, had a great success. Raynouard was admitted to the academy in 1807, and from 1817 to 1826 he was perpetual secretary. He was admitted to the Academy of Inscriptions in 1816. His later life was spent in studying the Provençal language and literature. His chief works are *Choix de poésies originales des troubadours* (6 vol., 1817-22), of which the sixth volume, *Grammaire comparée des langues de l'Europe latine dans leurs rapports avec la langue des troubadours* (1822), was separately published; and *Lexique roman* (6 vol., 1838-44). He died at Passy on Oct. 27, 1836.

RAYON: see SYNTHETIC FIBRES.

RAYONNANT STYLE, in architecture, the fully developed French Gothic style (see GOTHIC ARCHITECTURE) of the latter half of the 13th and the first three quarters of the 14th centuries. It is characterized by a complete mastery of the structural ideas of the Gothic vaulted church; great skill in stone cutting; the elimination of wall surface; the reduction in area of all supports to the minimum; thorough development and lavish use of bar tracery (*g.v.*) based on geometric forms; reduction in size and importance of the triforium gallery, and a general attempt to accent all vertical lines. In carved ornament the spherical crocket of the earlier Gothic was replaced by a fully opened, upturned leaf, and naturalistic foliage decorated capitals, string courses and the like. Figure sculpture was lavishly used around entrance doors, and in its combination of decorative validity and realistic presentation, it approached Greek sculpture of the 5th century A.C. Toward the end of the period, realism in sculpture became dominant and the decorative value of the work diminished. Characteristic examples are: later portions of Amiens cathedral (apse completed 1269, side chapels 1292-1375); transept and side chapels of Notre Dame at Paris (1258-1315); Sainte Chapelle, Paris (1245-48); S. Urban at Troyes (1262-76), famous for its delicate tracery and enormous window area; the Portal des Libraires at Rouen cathedral (1280); and the east end of the great abbey church of S. Ouen at Rouen (choir and transepts begun 1318).

RAYY, one of the great cities of Iran, the ancient Ragha, Latin *Rhages*. The expedition of the Boston and Pennsylvania museums disclosed a prehistoric settlement on the site dating from the third millennium B.C. Rayy is mentioned in the Avesta as a sacred place and is also mentioned in the Apocrypha. The city was well known to classical authors, who referred to it frequently. It was less important in Sasanian times, but in the 9th century, the Caliph Al-Mahdi became governor and there his son, Haroun-al-Rashid, was born. Under Al-Mahdi's rule the city rapidly became a magnificent metropolis, rivalled in western Asia only by Damascus and Baghdad. It covered at least 25 sq. mi., and according to Mustawfi it contained 20,000 mosques, 2,750 minarets, innumerable baths and colleges. Yaqut refers to it as a city of extraordinary beauty, built largely of fired brick, brilliantly ornamented with blue faience, but he also speaks of the dark and crooked streets which made the city a formidable obstacle to invaders. It continued to be a city of political, commercial and artistic importance through Seljuk times. In the 12th century it

was tortured and greatly weakened by the fury of rival religious sects, was overcome by the Mongols in 1220 and, according to some probably much exaggerated reports, completely destroyed and the inhabitants massacred. Mongol occupation, however, terminated the dominance of Rayy. It was famous for its decorated silks of an unsurpassed *finesse* and artistic perfection, of which fragmentary examples are to be found in the world's principal museums. Rayy has been wrongly credited with the bulk of the luxurious type of Persian pottery of the 12th and 13th centuries. (See POTTERY AND PORCELAIN: *Persia and the Near East*.) Only one architectural monument, the tower of Toghrul (1137) survives. The centre of Rayy was situated about 6 mi. S. of the modern Tehran.

RAZIN, STENKA (STEPHEN TIMOFEEVICH) (d. 1671), Cossack hetman and rebel, whose parentage and date and place of birth are unknown. We first hear of him in 1661 on a diplomatic mission from the Don Cossacks to the Kalmuck Tatars, and in the same year we meet him on a pilgrimage of 1,000 miles to the great Solovetsky monastery on the White Sea "for the benefit of his soul." After that all trace of him is lost for six years, when he reappears as the leader of a robber community established at Panshinskoe, among the marshes between the rivers Tishina and Ilovlya, from whence he levied blackmail on all vessels passing up and down the Volga. His first considerable exploit was to destroy the "great water caravan" consisting of the treasury barges and the barges of the patriarch and the wealthy merchants of Moscow. He then sailed down the Volga with a fleet of 35 galleys, capturing the more important forts on his way and devastating the country. At the beginning of 1668 he defeated the voivode Yakov Bezobrazov, sent against him from Astrakhan, and in the spring embarked on a predatory expedition into Persia which lasted for 18 months. Sailing into the Caspian, he ravaged the Persian coasts from Derbent to Baku, massacred the inhabitants of Resht, and in the spring of 1669 established himself on the isle of Suina, off which, in July, he annihilated a Persian fleet sent against him. Stenka, as he was generally called, had now become a potentate with whom princes did not disdain to treat. In Aug. 1669 he reappeared at Astrakhan, and accepted a fresh offer of pardon from the tsar there. In 1670 Razin rebelled against the government, captured Cherkassk, Tsaritsyn and other places, and on June 24 burst into Astrakhan. After massacring all who opposed him, and giving the rich bazaars of the city over to pillage, he converted Astrakhan into a Cossack republic. After a three weeks' carnival of blood and debauchery Razin quitted Astrakhan with 200 barges full of troops to establish the Cossack republic along the whole length of the Volga, as a preliminary step toward advancing against Moscow. But his forces were stayed by the resistance of Simbirsk, and after two bloody encounters close at hand on the banks of the Sviyaga (Oct. 1st and 4th), Razin was ultimately routed and fled down the Volga.

But the rebellion was by no means over. The emissaries of Razin, armed with inflammatory proclamations, had stirred up the inhabitants of the modern governments of Nizhny-Novgorod, Tambov and Penza, and penetrated even so far as Moscow and Great Novgorod. It was difficult to rouse the oppressed population by the promise of deliverance from their oppressors. Razin proclaimed that his object was to root out the boyars and all officials, to level all ranks and dignities, and establish cossackdom, with its corollary of absolute equality, throughout Muscovy. Even at the beginning of 1671 the issue of the struggle was doubtful. Eight battles had been fought before the insurrection showed signs of weakening, and it continued for six months after Razin had received his quietus. At Simbirsk his prestige had been shattered. Even his own settlements at Saratov and Samara refused to open their gates to him, and the Don Cossacks, hearing that the patriarch of Moscow had anathematized Stenka, also declared against him. In 1671 he was captured at Kagalnik, his

last fortress, and carried to Moscow, where, on June 6, after bravely enduring unspeakable torments, he was quartered alive.

See N. I. Kostomarov, *The Rebellion of Stenka Razin* (Rus.) (2nd ed. Petersburg, 1859); S. M. Solov'ev, *History of Russia* (Rus.), vol. II (Petersburg, 1895, etc.); R. N. Bain, *The First Romanovs* (London, 1903).

RAZMAK, a military cantonment in Waziristan region, North-West Frontier province, Pakistan, was opened after suppression of the Waziristan rebellion which followed the Afghan war of 1919. It is some 6,500 ft. above the sea, on the borders of Mahsud and Waziri territory.

RAZOR. The razor is an instrument used for shaving. The early razor of modern times was made of steel which had a wedge-shaped section, with straight sides tapering to a sharp edge, and although simple in form it was a good and durable instrument for its purpose. Early in the 19th century, the practice was introduced of hollowing out the sides of the blade by grinding, to facilitate sharpening the blade, and improve fineness of the cutting edge. At first the degree of hollowness, or concavity of the sides of the blade was small, but with great skill, hollow-grinding has been carried considerably further, increasing the lightness and flexibility of the blade. The full hollow blade is thinner in the centre than nearer the cutting edge. Hollow-grinding is performed by using grinding wheels of successively diminishing diameters. The processes of the production of the blade are:—forging under the hammer, marking with name of maker, drilling the hole for the pin, then hardening and tempering of the blade; grinding and hollowing; glazing and buffing on small leather-covered wheels with polishing material. The blade is then etched, fitted with handle, whetted to a fine sharp edge. Etching is sometimes elaborate.

Safety Razor.—The razor is naturally considered a dangerous instrument, and many attempts have been made to make it safe. Not until the introduction of the "Gillette" type of razor, at the beginning of the 20th century, was a satisfactory solution found. The principle of the "safety" razor is to place a guard between skin and cutting edge of the razor blade, so that the guard permits the edge to pass over the uneven surface of the part to be shaved, removing the hair without cutting the skin. In some cases devices are provided to enable the user to strop or resharpen the blades. The quality of the steel strip supplied by the steelmaker for use as blades in the safety razor is the result of a combination of the highest grade of skill and experience on the part of the steelmaker and the rolling-mill engineer. Cutting edges of the blade are formed by whetting on suitable wheels.

Other types of safety devices are based on the desire to retain the general form of the ordinary razor, while rendering it safe in use. These take the form of fitting a suitable guard to the blade of the ordinary razor, or the substitution of a holder, carrying an adjustable blade of the strip-steel type.

Electric Razor.—With the invention of the Schick Dry Shaver by the late Lieutenant Colonel Jacob Schick, U.S.A., retired, an entirely new technique was introduced to the art of shaving. This dry shaver consists of a shearing head mounted on a powerful little motor encased in a handle made of some suitable substance, such as bakelite. The shearing head includes an outer and an inner member—the outer member having a very thin shear plate with openings or slots in it to rest against the skin, while the inner member has teeth which co-operate with the nether edges of the walls of the shear plate slots or openings in a shearing action. The toothed inner member is held up tightly against the inside surface of the shear plate by means of springs or other appropriate means and is made to reciprocate very rapidly underneath the shear plate by the motor at approximately 7,000 times a minute. The hairs of the face which penetrate the openings or slots in the shear plate are thus sheared off by the reciprocating motion of the inner member in co-operation with the nether edges of the slot-walls of the stationary shear plate. The electric dry shaver operates without the use of sharp blades, soaps, brushes, creams and lotions.

RAZORBILL or **RAZOR-BILLED AUK**, *Alcaorda*, a member of the Auk family, known also as Marrot, Murre, Scout, Tinker or Willock; some of these names it shares with the Guillemot (*g.v.*), and Puffin (*g.v.*). It is a common sea bird of the north Atlantic, resorting in vast numbers to certain rocky cliffs for

breeding, and returning to the open sea for the rest of the year. It is in many respects intermediate between the guillemot and the gannet (*g.v.*). In habits the razorbill agrees with the guillemots, laying its single egg on ledges of cliffs. It breeds on both sides of the north Atlantic, wandering as far south as the Mediterranean on the east and Long Island on the west in winter. It feeds on fish.

RAZZIA (an adaptation of the Algerian Arabic *ghaziah*, from *ghazi*, to make war), a foray or raid made by African Moslems. As used by the Arabs, the word denotes a military expedition against rebels or infidels, and razzias were made largely for punishment of hostile tribes or for the capture of slaves. English writers in the early years of the 19th century used the form *ghazzie*, and Dixon Denham in his *Travels* (1826) styles the raiding force itself the *ghazzie*. The modern English form is copied from the French, while the Portuguese variant is *gasia*, *gasiva*.

RÉ, ÎLE DE, an island 1½ mi. off the port of La Pallice in the southwestern part of France. The island, with a northwest-southeast length of 15 mi. and an average width of 2½ mi., is separated from the coast of Vendée to the north by a shallow bay, the Pertuis Breton, 6 mi. broad, and from the island of Oléron to the south by another, the Pertuis d'Antioche, 7½ mi. broad. The Atlantic coast is reef-fringed, but there are small-craft harbours on the landward side. The most important of these is La Flotte. The largest shore indentation on the east coast, the Fier d'Ars, nearly divides the island, leaving an isthmus only 230 ft. wide to maintain the island's continuity. Dunes and salt marshes cover a large part of the northern end of the island. Many salt pans for the collection of salt by evaporation have been built along the landward shore. Industries are fishing, oyster cultivation, and the collection of seaweed for fertilizer. The island has some cropland which is in vineyards or in early spring vegetables. Île de Ré is included in the department of Charente-Maritime. Population of the island (1946), 7,908.

REA, SAMUEL (1855-1929), U.S. railroad official, was born at Hollidaysburg, Pa., on Sept. 21, 1855. In 1871 he entered the service of the Pennsylvania railroad as chainman and rodman. From 1875 to 1877 he was assistant engineer on construction of the Monongahela river bridge at Pittsburgh. He was next appointed assistant engineer for the Pittsburgh and Lake Erie railroad and returned to the Pennsylvania lines in 1879 in a similar capacity. In 1888 he was appointed assistant to the second vice-president of the Pennsylvania railroad, which position he retained until 1889 when he was made chief engineer on construction of the belt line tunnel under Baltimore for the Baltimore and Ohio railroad.

In 1892 he again returned to the Pennsylvania railroad as assistant to the president, and became first vice-president in 1911. In 1913 he was elected president. He was in charge of the construction of the Pennsylvania station in New York city (completed in 1910), the connecting tunnels under the Hudson and East rivers, the New York Connecting railroad and Hell Gate bridge over the East river (opened in 1917). In 1917 he became a member of the executive committee on national defense of the American Railway association, known as the Railroads War Board. He retired from the presidency of the Pennsylvania railroad on Sept. 30, 1925. He died at Gladwyne, Pa., on March 24, 1929. He wrote *The Railways Terminating in London* (1888).

REACTION KINETICS is that branch of physical science which deals with the determination and interpretation of the rates of chemical change. The subject includes the consideration of the rates both of everyday but complicated reactions such as hard-boiling an egg (an example of protein coagulation) and of simpler but less commonplace reactions such as the one between hydrogen and chlorine. Rates have been measured for slow reactions (*e.g.*, the disintegration of ordinary uranium, only half of which will decompose in 5,000,000,000 years) and for fast reactions (*e.g.*, the dissociation of oxygen from haemoglobin, which is almost complete in a tenth of a second). An attempt is made in each case to show upon the reaction velocity, and to describe in as much detail as possible the behaviour of the molecules at the moment of their reaction.

Many familiar processes involve chemical reactions which proceed at measurable rates. For example, the rusting of iron, the fermentation of sugar, the "drying" of paint, the hardening of plaster of Paris, the baking of bread and the growth of plants, all involve chemical reactions of greater or lesser complexity, and for each example there is considerable interest in the rate of reaction. In general, these familiar processes are very complex, partly because many of the materials are not single pure compounds, but mixtures. It is well known, however, that the rusting (oxidation) of iron requires both air and water, and that the reaction proceeds much more rapidly near the ocean (where salt is deposited on the iron) than it does elsewhere. The rate of rusting also depends upon the composition of the metal (pure iron and stainless steel corrode less rapidly than do cast iron and mild steel) and on temperature (corrosion is rapid in a stream of steam and air). (See CORROSION AND OXIDATION OF METALS.)

Scientists have been largely concerned with measuring the rates of reactions such as the decomposition of ozone, the oxidation of sulphur dioxide and the nitration of hydrocarbons; they assume that an understanding of these and similar reactions of pure chemicals will eventually lead to an understanding of more complex (if more familiar) reactions.

Studies of reaction velocity have not only played a fundamental role in the growth of theoretical chemistry; the concepts developed in these studies have also been highly fruitful in industry, especially in the field of catalysis (*q.v.*). A case in point is the Haber process for the manufacture of ammonia (*q.v.*), which is based in part on studies of reaction kinetics. Both theoretical and practical research in the field of reaction kinetics was by mid-century under way in hundreds of laboratories.

A specific example of a rate study is the work on the decomposition of hydrogen iodide to form hydrogen and iodine.

This reaction proceeds at a rate convenient for measurement in the neighbourhood of 320° C., at which temperature not only the hydrogen and hydrogen iodide but even the iodine is gaseous. (This reaction is a reversible one; however, for the moment, it is better to postpone discussion of this complication and to consider only the reaction as written.) The rate of decomposition of hydrogen iodide increases as the quantity of hydrogen iodide per unit volume is increased; quantitatively, the rate is proportional to the square of the concentration of hydrogen iodide. The rate increases by a factor of 1.9 when the temperature is increased from 320° C. to 330° C. The reaction occurs within the body of the gas, and not on the glass walls of the vessel in which the experiment is performed.

The facts just cited have been interpreted to indicate that when two molecules of hydrogen iodide collide, a chemical change occurs only if the velocity of one of them with respect to the other exceeds 2.4 km./sec. (about 5,000 m.p.h.). The average diameter (so far as collision is concerned) of these hydrogen iodide molecules can also be calculated from the kinetic data; it is of an order of magnitude (0.8×10^{-8} cm.), roughly consistent with the results of other measurements of the sizes of molecules. The effective collisions (*i.e.*, those which lead to reaction) result in a simple interchange of atoms; here the hydrogen and iodine atoms in each of the two colliding molecules of hydrogen iodide separate; simultaneously, the two hydrogen atoms combine to form a hydrogen molecule, and the two iodine atoms combine to form an iodine molecule.

For the discussion of even the simple example of the decomposition of hydrogen iodide, it has been necessary to employ the elementary concepts of chemistry (*q.v.*) and of the kinetic theory (*q.v.*) of matter. For the more detailed treatment of reaction kinetics which follows, a somewhat more extensive knowledge of these subjects is assumed. In the last sections of this article, a precise presentation is attempted.

History.—Gross differences in the rates of chemical reactions have long been recognized. By the beginning of the 19th century, several instances were known where the rate of a chemical change could be greatly increased by adding to the reacting system a small quantity of some apparently inert material. For example, it was discovered in 1796 that the dehydrogenation of alcohols pro-

ceeds much more rapidly in the presence of metals than it does in their absence. In 1836, Jöns Jakob Berzelius grouped together many reactions of this type and gave the name "catalysts" to the materials which accelerate chemical change. (The modern definition of catalysts is given below.) Although the qualitative concept of reaction rate was by that time well established, the first quantitative measurement and mathematical formulation of reaction velocity is generally credited to L. F. Wilhelmy, who, in 1850, measured the rate of "inversion" (hydrolysis) of cane sugar.

Definitions.—Chemical reactions can be classified as homogeneous or heterogeneous. Homogeneous reactions are those (like the decomposition of hydrogen iodide) which occur completely within one phase (gaseous, liquid or solid). Heterogeneous reactions are those (like the reaction between a metal and an acid) where the reactants are components of two or more phases (solid and gas, solid and liquid, two mutually immiscible liquids, etc.) or where one or more reactants undergo chemical change at an interface; i.e., on the surface of a solid catalyst.

Reactions may also be classified as "reversible" or "irreversible." An irreversible reaction is one in which the reactants, if mixed in the proper proportions, are almost completely converted to the reaction products; a reversible reaction is one in which appreciable quantities of all the reactants and of all the reaction products are present in the system no matter how long the reaction is allowed to proceed. The mixture eventually formed in such a reversible reaction is called the equilibrium mixture; the same equilibrium mixture may be prepared from suitable amounts of either the reactants or the reaction products. For example, the same equilibrium mixture of hydrogen, iodine and hydrogen iodide (at definite temperature and pressure) can be prepared by starting either with equivalent quantities of hydrogen and iodine or with pure hydrogen iodide. If the definition of equilibrium is that adopted in thermodynamics (*q.v.*), then every reaction is, in principle, reversible. There are reactions, however, where the extent of the reverse reaction is too small to be detected by any experimental means at present known; such reactions are usually regarded, for the purposes of kinetics, as irreversible.

"Order" of Reaction.—The fundamental law of reaction kinetics was developed by C. M. Guldberg and P. Waage around 1867 (an independent and similar formulation was made by Jacobus Henricus van't Hoff). These authors assumed that, at constant temperature, the rate of any simple chemical reaction is proportional to the product of the concentrations of the various reacting substances. They showed in a general way that their law of chemical change is consistent with the kinetic molecular theory of matter, and that the data for many chemical reactions could be formulated quantitatively in terms of their theory. Since 1870, the concepts of Guldberg and Waage have been extended and modified, but most of reaction kinetics is still based upon their work.

Consider the simple homogeneous, irreversible reaction between two compounds, A and B (the reactants), to form C and D (the reaction products).

An example of this sort of reaction is the saponification of ethyl acetate by alkali:

Equations (2) and (2') are written represent the stoichiometry of the chemical change; i.e., the equations show the relationship between the weights of the initial reactants and those of the final products. The reaction rate may be proportional to the concentrations of the reactants which appear in the stoichiometric equation; if, however, the reaction occurs in several consecutive chemical steps, or requires a catalyst, the kinetics may be more complicated

(see below) than those which could be implied from the stoichiometry. The treatment for a simple case follows.

At the beginning of the reaction, the compounds A and B are present in definite concentrations, say a_0 and b_0 moles per litre respectively¹; the concentrations of C and D are zero. As the reaction proceeds, the concentrations of A and B decrease, whereas the concentrations of C and D increase. If the concentrations of A and B at any instant are represented by the symbols (A) and (B), then the law of Guldberg and Waage states that wherever equation (2) represents the true kinetic course of the reaction, the reaction velocity, v , is proportional to (A) and to (B). This statement in mathematical form is

$$v = k(A)(B) \quad (3)$$

where k , the proportionality factor, is called the rate constant. Note that the rate of reaction, v , and the rate constant, k , are not the same, but are connected by an equation of the form of (3).

An equation such as (3) may accurately describe the rate of a chemical reaction. Unfortunately, however, a good experimental method for directly measuring the rate, v , of a reaction is usually not to be found. The quantities which can usually be determined experimentally are the time and the concentrations of the reactants or reaction products. An equation such as (3) can be transformed by the methods of calculus (*q.v.*) into an equation expressing a relationship between these concentrations and time. Although the details of this transformation are in no way necessary for the succeeding argument, they are nevertheless presented here for the sake of continuity.

If the concentration of C at any instant is represented by x , then the rate, v , of formation of C is dx/dt , the derivative of x with respect to time; and equation (3) can be replaced by (3').

$$v = \frac{dx}{dt} = k(A)(B) = k(a_0 - x)(b_0 - x) \quad (3')$$

The integrated form of equation (3) is

$$\log_e \frac{b_0(a_0 - x)}{a_0(b_0 - x)} = kt(a_0 - b_0) \quad (4)$$

where t is the time measured from the beginning of the reaction; the other symbols have been previously defined. In principle, it should be possible to obtain for every reaction an equation, analogous to (4), from which the concentrations of the various reactants and products at any moment may be calculated.

One method of testing experimentally whether equations (3) and (4) adequately describe the rate of any particular reaction is to measure x (the concentration of C) at several different times, t . An attempt is then made to choose a single value for the rate constant k such that all the sets of corresponding values of x and t satisfy equation (4). If this attempt is successful, the experiment is then repeated at the same temperature but with different initial concentrations (a_0 and b_0) of A and B. If and only if these new data also satisfy equation (4) with the rate constant k unchanged, the demonstration that the reaction obeys the rate equations (3) and (4) is complete. The constant, k , is thus independent of the initial concentrations of A and B; it is, however, a function of the temperature and it depends on course

FIG. 3.—SUCCESSIVE FIRST ORDER REACTIONS, WHERE THE RATE CONSTANT OF THE SECOND IS FOUR TIMES AS GREAT AS THAT OF THE FIRST (DIAZOTIZATION OF PHENYL MERCURIC NITRATE IN 20% HNO_3 WITH 0.16 M HNO_3)

¹ For reactions in the gas phase the partial pressure of each gas is used as a measure of its concentration.

² Where $a_0 = b_0$, the corresponding equation is $\frac{x}{a_0(a_0 - x)} = kt$

FIG. 2.—RATES AT WHICH EQUILIBRIUM IS ESTABLISHED BETWEEN THE TWO FORMS OF BROMONITROCAN. PHOR

upon the chemical nature of the reactants A and B. Fig. 1 is a graphical representation of equation (4) for the saponification of ethyl acetate.

If the equations for various chemical reactions are treated as was equation (3) for reaction (x'), then these reactions fall into a number of different classes. A reaction, the rate of which may be described by an equation of the form

$$v = k(A) \quad (5)$$

is called a first order reaction; one described by an equation of the form

$$v = k(A)^2 \quad \text{or} \quad v = k(A)(B) \quad (6) \text{ or } (6')$$

is called a second order reaction, etc. In general, a reaction the rate of which may be described by the equation

$$v = k(A)^m(B)^n(C)^p(D)^q \dots \quad (7)$$

is called a reaction of order r , where $r = m + n + p + q + \dots$. Such a reaction is said to be of order m with respect to A, of order n with respect to B, etc. (Some reactions may be of nonintegral order; e.g., half-order. The majority of known reactions are of first or second order.)

In certain reactions, such as the inversion of cane sugar,

the rate is proportional to the concentration of some substance (in this instance, the hydronium ion of the acid) (see ACIDS AND BASES), which does not appear among either the reactants or the reaction products in the chemical equation; the reaction cited (equation (8)) is said to be catalyzed by hydronium ion H_3O^+ , or hydrated hydrogen ion.

$$v = k(C_6H_5O_6)(H_3O^+) \quad (9)$$

If the catalyst is one of the reaction products, the reaction is said to be autocatalyzed.

Reversible Reactions.—The reactions hitherto described have been assumed to be irreversible, in the sense defined above. If the reaction between the compounds A and B, on the one hand, and C and D, on the other, is reversible, then equation (2) must be rewritten.

Wherever equation (x'') represents the true kinetic course of the reactions, the rates v_f of the "forward" and v_r of the "reverse" reactions are given by equations (10) and (10').

$$v_f = k_f(A)(B) \quad (10)$$

$$v_r = k_r(C)(D) \quad (10')$$

If the reaction is begun by mixing A and B (either pure or in solution), the initial concentrations of C and D are each zero; hence the rate, v_r , of the reverse reaction is also zero. However, as A and B react to form C and D, these products in turn react to regenerate A and B. The net rate at which C and D are formed is therefore the difference between v_f and v_r .

$$v = v_f - v_r = k_f(A)(B) - k_r(C)(D) \quad (11)$$

The net rates of the forward and reverse reactions for a particular case are shown graphically in fig. 2. In the reaction in ques-

FIG. 4A.—MAXWELL-BOLTZMANN DISTRIBUTION OF PAIRS OF MOLECULES OF HYDROGEN IODIDE (AT 300° C. AND AT 400° C.). THE VELOCITY OF ONE MEMBER OF ANY PAIR RELATIVE TO THE OTHER MEMBER OF THE PAIR IS μ .

As the latter reaction proceeds, P is converted into N; hence, the forward rate decreases and the reverse rate increases. Eventually, the two rates become equal, and the net rate, v , is zero; thus, a dynamic equilibrium is achieved. This state of dynamic equilibrium is not a condition in which no reaction occurs, but is

one in which the rates of the forward and reverse reactions are equal. This kinetic concept of dynamic equilibrium has been experimentally verified by the use of radioactive tracers (see ISOTOPES).

When, for a reaction which follows equation (x''), the forward and reverse reactions proceed at equal rates, it is seen that

$$v_f = v_r = k_f(A)(B) = k_r(C)(D) \quad (12)$$

From equation (12) it follows that

$$\frac{(C)(D)}{(A)(B)} = \frac{k_f}{k_r} = K_e \quad (13)$$

where K_e , the ratio of the rate constants for the forward and reverse reactions, is called the equilibrium constant. Equation (13) gives the relative concentrations of the compounds A, B, C, and D at equilibrium; these concentrations need not be even approximately equal, for in general the rate constants of the forward and reverse reactions differ considerably from one another.

An equation analogous to (13) but more general is obtained by a parallel treatment of a reaction (7). Although this more general expression is correct as a first approximation, it nevertheless disagrees with the precise thermodynamic definition of equilibrium. Consideration of this and similar difficulties is postponed to the sections on collision theory and on activated-complex theory.

Complex Reactions.—The reactions so far considered are of simple types; all sorts of combinations of these types are possible. For example, reactions sometimes occur in several steps.

Here the rate of formation of B is proportional to the concentration of A, and the rate of formation of C is proportional to the concentration of B. Since, initially, the concentration of B is zero, the initial rate of formation of C is zero. Fig. 3 shows graphically the concentration of C at any time, t , in a system where the rate constants for the two consecutive reaction steps are of comparable magnitude. Other cases of interest are those in which one of the successive reactions is reversible, or of second order, etc. Considerable complexity is not only possible but common.

What has already been said makes it evident that the kinetic equation for a reaction cannot be inferred from the chemical equation, which gives only the relationship between the weights of reactants which will combine with one another and the weights of the final products (i.e., the stoichiometric relations). The kinetic expression, it is true, must account for the stoichiometric findings, but it should do more than that. Usually more than one reaction path between the initial reactants and the final products is conceivable. Under favourable conditions kinetic considerations permit the selection of just one of these reaction paths, and kinetic measurements demonstrate that the path selected, and no other, is the one which the reaction takes. Under less favourable conditions, kinetic considerations are insufficient to eliminate all reaction paths but one. Even here, however, they serve to rule out many of those paths which from mere stoichiometric considerations might be considered possible.

A simple example will illustrate the ideas just expressed. A chemist might investigate an irreversible reaction, the stoichiometric expression for which is $A \rightarrow C$. This expression means that each molecule of the reactant A is converted (eventually) into one molecule of the product, C. It does not tell whether each molecule of A is converted directly into a molecule of C or whether each molecule of A is converted first into a molecule of an intermediate, B, which is in turn converted into a molecule of C. In the former instance, the proper kinetic expression for the reaction $A \rightarrow C$ may coincide with the stoichiometric expression. In the latter instance, the proper kinetic expression is $A \rightarrow B \rightarrow C$. Measurements of the extent of the reaction at various stages in its course are often sufficient to decide questions of the kind here raised. In the particular instance cited, if the reaction followed a curve of the sort shown in fig. 3, that fact would show that the kinetic expression for the reaction was $A \rightarrow B \rightarrow C$. If, on the other hand, the reaction followed a curve predicted from equation (5), and somewhat resembling the one shown in fig. 1, that fact would show that the kinetic expression for the reaction was $A \rightarrow C$, coinciding with the stoichiometric expression.

This fact alone would not rule out compound B as an intermediate, but it could be an intermediate in the reaction only under certain special circumstances (*i.e.*, the reaction $B \rightarrow C$ would have to be very fast as compared with the reaction $A \rightarrow B$).

If any individual reaction is to be thoroughly understood, its reaction kinetics must be investigated. The object in view is to determine by inference from the kinetic measurements whether the reaction proceeds in one or more stages, to determine the order of each reaction stage with respect to each one of the reactants, and to determine for each particular stage whether or not it is catalyzed by some substance (possibly an ion) which does not appear in the stoichiometric expression for the over-all reaction. It should, however, be stated that kinetic considerations by themselves, although they greatly aid in the treatment of the problem stated, are often insufficient for its solution in all details.

If a kinetic study shows that two molecules (of the same or of different compounds) react with one another directly, then the reaction is said to be bimolecular. In a many-stage reaction, some individual step may be bimolecular, although the over-all reaction is not of second order and may indeed (like [14]) be of no definite order. It is likewise possible for a reaction to be of the second order, but to contain no single step which is truly bimolecular. The interpretation of the reaction kinetics for any individual reaction is thus a difficult matter, and for many important reactions the conclusions are still tentative.

Application of the Kinetic Molecular Theory.—Guldberg and Waage assumed that the rate of any reaction is proportional to the product of the concentrations of the reactants (equation [7]); they interpreted this hypothesis in terms of the kinetic molecular theory. The number of collisions between the molecules of compound A and the molecules of compound B is proportional to the product $A(B)$ of their concentrations; Guldberg and Waage's law amounts then to a statement that molecules react only if they collide, and that the rate at which they react is proportional to the number of collisions per second.

But although reaction between two molecules cannot occur unless these molecules collide, it does not follow that reaction must occur every time two molecules collide, even though these are molecules of substances which can react chemically one with another. For most reactions, it has been fully determined that the vast majority of collisions are "elastic"; *i.e.*, that the molecules rebound from one another without chemical reaction. It is possible by means of the kinetic molecular theory to compute the number of collisions per second between the molecules of two compounds which are present in a solution or a gas in known concentrations. For example, the number of collisions between pairs of molecules of hydrogen iodide at a temperature of 320° C. and a total pressure of one atmosphere is approximately 10^{23} per cubic centimetre per second. Under the conditions stated, there are only about 10^{18} molecules of hydrogen iodide in a cubic centimetre of gas. Hence, if every collision between two molecules of hydrogen iodide led to chemical change, the reaction would be over in a small fraction of a second, too short a time indeed to measure. It has been computed that in the system described, only one collision in about 10^{15} leads to chemical change.

Temperature Coefficients of Reaction Rates.—Another (and historically older) consideration leading to the conclusion that not all collisions cause reaction is based on the increase of reaction rates with increase in temperature. According to kinetic-molecular theory, the number of collisions between molecules of two compounds present at definite concentrations increases as the square root of the absolute temperature. For example, the number of collisions at 25° C. (298° absolute) is only about 1.5% greater than the number at 15° C. (288° absolute). But the rates

of most reactions increase by a factor of two or more when the temperature is raised by 10° C.; as much material may react in an hour at 100° C. as in a year at 0° C. In some instances, such as the denaturation of egg albumin, the reaction rate increases one hundredfold when the temperature is raised 10° C.

However, the assumption that only those molecules which collide with high energy of impact react with one another not only furnishes an explanation for the high temperature coefficients of reaction rates, but also accounts for the fact that collisions effective in bringing about chemical change are usually rare. To bring out the connection between the assumption and the conclusions, it is necessary to consider the velocity of one molecule relative to another. This relative velocity is not the same for all colliding pairs, but there is a determinable probability that for any one particular pair the relative velocity will be close to any chosen value, u , of the relative velocity. This probability is calculated from the Maxwell-Boltzmann distribution curve (see KINETIC THEORY OF MATTER) shown in figs. 4a and 4b for hydrogen iodide at 300° C. and 400° C. The horizontal co-ordinate represents the velocity, μ , in km./sec. of one molecule of hydrogen iodide relative to the one with which it collides; the vertical co-ordinate represents the probability that the relative velocity is μ . (More precisely, the ordinate is equal to $1/N_0 d(N^2)/d\mu$, where N_0 is the total number of molecules under consideration, and $d(N^2)$ is the number of pairs of molecules with velocity lying between μ and $\mu+d\mu$.) Fig. 4b is an enlargement in vertical scale of part of fig. 4a. Figs. 4a and 4b indicate (1) that only a minute number of molecular pairs have relative velocities in excess of the 2.4 km./sec. required for reaction (see above), and (2) that, although the average value of the relative velocity is not greatly increased by raising the temperature from 300° C. (573° absolute) to 400° C. (673° absolute), the number of molecular pairs with high relative velocities is increased by a large factor. Thus the assumption that reaction is limited to molecular pairs with high relative velocities at the moment of collision qualitatively explains both the fact that few collisions are "effective" in producing reaction and the fact that the rates of most chemical reactions increase sharply with increase in temperature.

The complete equation (24) for the reaction rate derived from the kinetic collision theory is given in the next to last section of this article. Here it is sufficient to say that this complete equation is consistent (within experimental error) with an empirical equation (15) advanced by Svante Arrhenius in 1889 which has proved useful.

$$\log_e \frac{k_2}{k_1} = \frac{Q}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad (15)$$

In equation (15) k_1 and k_2 are the rate constants at the absolute temperatures T_1 and T_2 respectively, Q is a constant called the activation energy, and R is the gas constant (1.98 cal./mole degree) (\log_e refers to natural logarithms). The larger the value of Q , the more sensitive is the reaction rate to changes in temperature. Reactions with values of Q varying from less than 500 up to about 100,000 cal./mole have been discovered. Q divided by the number of molecules in a mole (Avogadro's number) is (roughly) equal to the relative kinetic energy of a molecular pair which is just sufficient to make the members of the pair react upon collision.

Reaction Mechanism.—In this section, it will be shown how reaction kinetics may be used to determine the path or mechanism of a somewhat puzzling reaction. The example chosen is the reaction in aqueous solution between acetone and bromine. Here the stoichiometric

expression (16) is of the same form as equation (2). In 1904, however, A. Lapworth discovered that the rate of this reaction is proportional to the concentration of the acetone and of the hydrogen bromide (one of the reaction products) but independent of the concentration of the bromine and of all other substances known to be present in the system. The kinetic equation, therefore, is

$$v = k(\text{CH}_3\text{COCH}_3)(\text{HBr}) \quad (17)$$

These facts suggest the hypothesis that the acetone is slowly converted into some reactive intermediate by the action of the acid;

this reactive intermediate then combines rapidly with bromine. The hypothesis has more recently been elaborated as follows:

The proposed reaction between the catalyst and the acetone results in the transformation of the acetone into a reactive intermediate (the "enolic" modification of acetone; see ISOMERISM: *Tautomerism*), which subsequently reacts rapidly with bromine. The rate, v , of the entire reaction is equal to that for the slowest step in the process, namely reaction (18'). The kinetic equation for this step is

$$v = k'[(\text{CH}_3)_2\text{COH}^+] \quad (19)$$

The concentration of water is essentially constant and does not enter into equation (19); its concentration can be included in the rate constant, k' . The ion $(\text{CH}_3)_2\text{COH}^+$ would be in equilibrium with the acetone and acid present in the solution if it were not for the reactions (18') and (18'') which slowly but essentially irreversibly remove some of this ion. The ion $(\text{CH}_3)_2\text{COH}^+$ is described as in pseudoequilibrium with acetone and acid, or as in a "steady state." The "steady state" concentration of the ion is given to a good approximation by the equilibrium expression

$$\frac{[(\text{CH}_3)_2\text{COH}^+]}{[(\text{CH}_3)_2\text{CO}][\text{H}_2\text{O}]} = K \quad (19')$$

When the theoretical equations (19) and (19') are combined, the experimentally verified kinetic equation (17) for the bromination of acetone is obtained; the rate constant k is the product of k' and K .

Not only does the mechanism presented in equations (18), (18') and (18'') agree with equation (17), but it will further explain many other facts. It is consistent, for example, with the observation that acetone reacts with chlorine, or with iodine at the same rate as it does with bromine. This is in accord with the proposed mechanism, since equation (18'), which does not involve the halogen at all, is postulated as the rate-determining step in the halogenation.

A more detailed investigation of the reaction has revealed that it is catalyzed not only by hydronium ion but also by molecules of un-ionized acids; it is also catalyzed by bases. The catalysis by un-ionized acid molecules can be accounted for by substituting equation (18'') for equation (18')

where B represents a molecule of any base. (The detailed mathematical analysis needed to prove the above statement, although beyond the scope of this article, is treated by L. P. Hammett in *Physical Organic Chemistry*.)

The proposed mechanism is thus consistent with a large and varied selection of quantitative kinetic evidence. This is a necessary condition, but not a sufficient one to establish the mechanism, it does, however, make the proposed mechanism quite probable.

Catalysis.—A catalyst is defined as a substance which increases the rate of a chemical reaction, but which can be recovered quantitatively and unchanged at the end of the reaction. There are many substances which (for specified reactions) approach this definition closely. Typical examples of homogeneous catalysis are the action of acids to increase the rate of hydrolysis ("inversion") of cane sugar, the action of bases to increase the rate of polymerization in the preparation of bakelite, the action of oxides of nitrogen in the chamber process for manufacturing sulphuric acid. Typical examples of heterogeneous catalysis are the action of finely divided iron to increase the rate at which nitrogen and hydrogen combine to form ammonia, the action of vanadium pentoxide to increase the rate at which sulphur dioxide and oxygen combine to form sulphur trioxide in the contact process for manufacturing sulphuric acid, and the action of finely divided nickel to

increase the rate at which hydrogen combines with vegetable oils to form solid fats (e.g., "Crisco"). (For a discussion of theory, manufacture and use of catalysts see CATALYSTS.)

Catalysts accelerate chemical reactions in various different ways. The bromination of acetone (cited above) illustrates one of the most common modes of action. Here the acid which in this case is the catalyst combines with one of the reactants (acetone) to form an intermediate chemical compound. Then, in a later step of the complex reaction, the catalyst is regenerated and so becomes available for further reaction. In this way the catalyst goes through a complete cycle, and a trace of catalyst increases the rate at which a large amount of material reacts.

It is interesting to note that a catalyst can increase the rate of a chemical reaction but cannot change its point of equilibrium. If this statement were not correct, it would be possible to construct a perpetual motion machine. Since perpetual motion is an impossibility (see THERMODYNAMICS), it follows that in a reversible reaction the catalyst must accelerate both the forward and the reverse rate and in the same proportion.

Photochemical Reactions.—Reactions which take place in the presence of light but not in the dark are called photochemical reactions; their rate depends upon the amount of light absorbed. This subject is treated fully in the article on PHOTOCHEMISTRY. The principles here needed are the following: (1) Only the light which is absorbed by the system is effective in promoting chemical change; (2) radiant energy (light) is available only in units called quanta (see LIGHT); (3) a molecule which absorbs light and is thereby activated (i.e., enters into a reaction with light) absorbs one and only one light quantum (A. Einstein). Subsequently, the activated molecule may enter into other, more complicated chemical reactions.

Chain Reactions.—Hydrogen gas reacts with chlorine at room temperature provided that the mixture is illuminated; the reaction (except under special circumstances, see below) does not occur in the dark. The form of the equation for the chemical reaction

resembles that of the reaction for the formation of hydrogen iodide (reverse of equation 1); the kinetics of the two reactions are, however, quite different. The reaction between hydrogen and chlorine proceeds when visible light is used. Since light of this wave length is absorbed by chlorine, but not by hydrogen, it follows that chlorine is the reactant affected by the light. Measurements have shown that as many as 1,000,000 molecules of hydrogen chloride are produced for every light quantum absorbed. Evidently a very special mechanism must be postulated to account for this fact. It has been assumed (W. Nernst, M. Bodenstein) that, as an indirect or direct result of the illumination, the molecules of Cl_2 which absorb light quanta are dissociated into chlorine atoms (21). These atoms then react as shown in equations (21') and (21'').

Each chlorine atom obtained by the illumination reacts with a molecule of hydrogen to produce a molecule of hydrogen chloride and an atom of hydrogen (21'); the latter in turn reacts with a molecule of chlorine to produce another molecule of hydrogen chloride and to regenerate an atom of chlorine (21''). The cycle is then repeated. Reactions characterized by such cycles are called chain reactions. If there were no side reactions to destroy the intermediate hydrogen and chlorine atoms, then, in principle, one chlorine atom could convert all the hydrogen and chlorine in the system to hydrogen chloride. In fact, the chain length varies from a few units to a million, depending upon the experimental conditions. The chains are broken (or terminated) when the chlorine or hydrogen atoms are removed. There are several means of removing these reactive atoms. For example, oxygen combines with either chlorine or hydrogen atoms, and traces of oxygen are effective in decreasing the rate of the reaction in question. In this reaction then, oxygen acts as a negative catalyst, or an inhibitor, or a chain breaker. (These terms are not, however, exactly synonymous.) Another means of breaking the chain is

the combination of hydrogen atoms and chlorine atoms present in the gas mixture to form hydrogen chloride. Such combination occurs on the walls of the vessel, or when a hydrogen atom and a chlorine atom, in what is called a three-body collision, collide simultaneously with some third particle (such as a chlorine molecule); interestingly, the combination does not occur when only a hydrogen and a chlorine atom collide. Such a combination independent of the wall or of any third particle would violate either the law of the conservation of momentum or the law of the conservation of energy, or both. (See MECHANICS.) The fact that no such combination is observed simply means that the molecular system in question obeys the laws of mechanics, as do the molecular systems in all similar reactions which have been carefully studied.

The validity of the proposed chain mechanism for the reaction between hydrogen and chlorine is supported (1) by the high photochemical yield of the reaction (*i.e.*, the large amount of hydrogen chloride produced per quantum of light absorbed), (2) by the fact that kinetic equations based upon the chain mechanism adequately describe the reaction velocity and (3) by experiments showing that the reaction can be initiated in the dark by the introduction into the reaction mixture of hydrogen or chlorine atoms from some outside source. There is good reason to believe that hydrogen atoms are produced by an electric arc discharge in hydrogen gas, and that chlorine atoms are produced in the reaction between sodium vapour and chlorine. If the products from either of these reactions are rapidly introduced into a mixture of hydrogen and chlorine, the formation of hydrogen chloride is initiated.

Reaction kinetics has provided much evidence to show that many reactions either in the gas phase or in solution proceed by chain mechanisms.

Heterogeneous Reactions.—Heterogeneous reactions include the solution of solids in solvents, and the reverse process, the crystallization of solids from solution. The reaction of metals with acids and problems of corrosion are part of the subject of heterogeneous reactions. However, by far the majority of the research on heterogeneous reactions is devoted to heterogeneous catalysis (*e.g.*, reactions between gases or liquids catalyzed by solids, etc.). For example, finely divided iron greatly accelerates the rate at which nitrogen and hydrogen unite to form ammonia. Recent studies have shown that iron adsorbs nitrogen in such a fashion as to activate it (by a reaction analogous to the formation of iron nitride); the hydrogen subsequently reacts with the adsorbed nitrogen. Although heterogeneous reactions of this sort are of considerable theoretical and practical interest (see ADSORPTION; CATALYSIS) the present article is devoted largely to a consideration of homogeneous reactions.

Enzymes.—Almost the earliest chemical reactions known are the fermentations by which sugar is converted to alcohol or vinegar (fermentation) or lactic acid (souring of milk). These and similar reactions occur in the presence of living organisms, such as yeasts, fungi, etc. In 1897 E. Buchner discovered that, in the fermentation of sugar, the function of the living yeast is to produce a catalyst for the reaction. He destroyed the yeast cells by grinding them with sand. The filtered juice, although it contained no living organisms, nevertheless rapidly converted sugar to alcohol. The complex organic catalysts produced by living cells are called enzymes; those so far investigated in detail have proved to be protein complexes.

The extensive investigation, largely by methods of reaction kinetics, of the fermentation of sugar has revealed the fact that the reaction is a complex one in which many enzymes take part. Active research is at present under way to elucidate the path of many enzymatic processes, and to determine if possible the detailed mechanisms by which enzymes function as catalysts.

There are enzymatic systems which convert starch into sugar and sugar into alcohol; others hydrolyze proteins into a mixture of amino acids; still others synthesize proteins in the body; such systems are responsible for the conversion (by a form of combustion) of sugar to carbon dioxide and water, with the liberation of energy. The accelerating effect of some of these enzyme systems is enormous. For example, one part of beef catalase can de-

tect in 25,000,000 parts of water by the acceleration it produces in the decomposition of hydrogen peroxide. Since the mechanism of enzyme action is unknown, and since the kinetics of enzyme action differs considerably from the kinetics of reactions accelerated by ordinary catalysts, direct comparisons are difficult and likely to be inaccurate. As a rough first approximation, however, catalase is about 10,000 times as active a catalyst as is an equal weight of ferrous ion in catalyzing the decomposition of hydrogen peroxide, and urease is about 10,000 times as active (at 20° C. and in neutral solution) as is an equal weight of sodium hydroxide in accelerating the hydrolysis of urea.

Explosions.—Chemical explosions are rapid reactions which are strongly exothermic; that is to say, these reactions are very rapid ones which evolve large quantities of heat. The hot gases formed in the chemical reaction, or the air heated by the energy released, produce a region of high pressure near the site of the explosion. This region of high pressure travels outward through the air in the form of an explosion wave which usually causes much of the destruction resulting from the explosion (see COMBUSTION; EXPLOSIVES). It is of interest to inquire what are the necessary conditions, and what are the possible mechanisms for a reaction which consumes many pounds of material in (say) 10⁻⁶ seconds. There are two well-known types of mechanism for explosions: the chain branching mechanism and the thermal mechanism. The latter type was suggested by Van't Hoff, the former by N. N. Semionoff; examples of both types have been discovered.

The theory of the chain-branching mechanism is that, during the early stages of a chain reaction, more chains are initiated per unit time than are terminated. The most spectacular example of an explosion caused by chain branching is the fission of atomic nuclei; such as occurs in atomic bombs. Here the disintegration of a particular sort of uranium, U²³⁸ (or of plutonium) is initiated by neutrons, but, in the disintegration, neutrons are also produced. (See ATOMIC ENERGY; ISOTOPES; NUCLEUS.) If exactly one neutron were produced from each disintegrating nucleus of U²³⁸, a chain reaction analogous to the reaction between hydrogen and chlorine would result. In fact, however, more than one neutron is produced by each nuclear disintegration; the average number is probably about two. An equation for the atomic disintegration is

where U, n, I and Y are the symbols for uranium, the neutron, iodine, and yttrium, respectively. (Other elements besides iodine and yttrium are also produced in the disintegration; the principles involved are, however, the same.) The faster the reaction proceeds, the more rapidly are neutrons produced and the more rapidly does the reaction rate increase. Since the disintegration of the uranium is accompanied by a large evolution of energy, the reaction is an explosion.

The second type of explosion mechanism is the thermal one. Most chemical reactions are carried out under conditions such that the heat evolved (or absorbed) by the reaction is taken away (or supplied) by the surrounding medium. If, however, a highly exothermic reaction is carried out under conditions such that the heat is not carried away by the surroundings, the reaction mixture must become hotter. At the more elevated temperature, the rate of the reaction is much greater; the rate of heat evolution, therefore, becomes much greater also, and the reaction mixture rapidly becomes still hotter. Such a reaction must necessarily lead to an explosion. The question whether a particular exothermic reaction will lead to an explosion is thus largely a question of the conditions under which the reaction is carried out. If the reaction can be made to proceed at such a rate that the heat lost to the surroundings per unit time is small compared with the heat input caused by the chemical reaction during the same interval, a thermal explosion ensues.

Reactions of Isotopes.—In general, the reaction rates of compounds which differ only in that they contain different isotopes of the same element are identical within experimental error. When, however, one of the lighter elements is involved, this need not be the fact. A compound which contains atoms of C¹⁴ (radioactive carbon) may react at a rate which differs appreciably (*e.g.*,

by 10%) from that of a compound identical except that it contains only normal carbon atoms. The rate of the reactions of compounds containing deuterium (heavy hydrogen) may, in certain cases, differ from those of the corresponding compounds of light hydrogen by a factor as large as eight. These large differences in rate, which may occur when a bond to a hydrogen atom is formed or broken, arise from an effect (zero-point vibrational energy) predicted by quantum mechanics (q.v.). Although a discussion of the theory of this effect is out of place here, the phenomenon is proving a most useful tool in investigations of reaction mechanisms.

The Collision Theory.—In the theory of reaction kinetics as so far presented, several difficulties have been noted. The present section is devoted to a discussion of these difficulties and the methods of avoiding them; a knowledge of physical chemistry on the part of the reader is assumed.

The ratio of the rates of a forward and of the corresponding reverse reactions gives an approximate expression for the equilibrium constant of the reaction in question, as shown for a special case by equation (13). In the more general case, an analogous treatment of the reaction

leads to equation (24).

$$\frac{(R)^p(S)^q(T)^r}{(A)^m(B)^n(C)^p} \dots = K_e \quad (24)$$

The ratio of concentrations on the left side of equation (24) is obtained even if the kinetic equation for the reaction is a complex one. For example, if the reaction is catalyzed, the catalyst concentration appears in the expression for the rate of both the forward and the reverse reaction; it thus cancels out in equation (24). Careful inspection shows that other possible complexities are likewise of no effect on K_e . But equation (24) is nevertheless not precisely correct. The true equilibrium expression (see THERMODYNAMICS) is defined in terms of the "activities," not the concentrations, of the reactants and reaction products. Although in dilute solutions the concentration of any substance closely approaches its activity, the two functions are by no means identical. (An analogous statement applies to gases at low pressure.) It is therefore clear that the law of Guldberg and Waage, although approximately correct, is not and cannot be uniformly valid.

The difficulty noted cannot be avoided by the assumption that reaction rates are proportional to activities rather than to concentrations; this assumption has been proved false by investigations of the rates of ionic reactions. The ratio of the activity of any substance to its concentration defines its activity coefficient. The activity coefficients of ions depend upon the ionic strength of the solution in which they occur. Solutions of simple electrolytes, such as NaCl , KCl , Na_2SO_4 , etc., are called "normal" solutions. The activity coefficients of ions in normal solutions are approximately equal to unity. In solutions of strong electrolytes, such as HCl , H_2SO_4 , NaOH , etc., the activity coefficients of ions are not equal to unity. In such solutions, the activity of an ion is not proportional to its concentration. It has been shown that only as a first approximation is this ratio proportional to the ionic concentrations.

The difficulty, at least insofar as ionic reactions are concerned, has been resolved by the assumption that reaction rates are proportional not to concentrations or activities, but to the number of collisions per second between the reacting ions. The number of collisions between charged particles should not be strictly proportional to the product of their concentrations. Let W be the ratio between the number of collisions among the reacting ions and the product of the ionic concentrations. Then, because of interionic effects, W should increase with increasing ionic strength for reactions between ions of like charge, and decrease with increasing ionic strength for reactions between ions of unlike charge. This predicted behavior is in qualitative agreement with the anomaly in ionic reaction rates already cited.

J. A. Christiansen's calculation (1924) based on the theory of P. Debye and H. Hückel, accounts quantitatively for the observed

rates of ionic reactions in dilute solution. Further, although the forward and reverse rates, taken separately, are not proportional to the activities of the reactants and reaction products, the expression obtained by setting equal the rates of the forward and reverse reactions (corrected to account for interionic effects) yields the thermodynamic equilibrium expression in terms of activities, not concentrations. How this happens is made clearer in the consideration (see below) of the activated-complex theory of reaction velocity. In general, it has been assumed that consideration of the actual number of collisions always leads to corrections for the law of Guldberg and Waage, such that the dynamic and thermodynamic equilibrium constants become equal.

It should be pointed out that interionic and other forces not only affect the change in the number of collisions with change in concentration; they also affect the actual number of collisions per unit time. Thus, in a reaction between two positively charged ions, forces of electrostatic repulsion lower the number of collisions far below that computed from the kinetic molecular theory. Furthermore, it is not true that every collision between reactant particles moving, relative to one another, with a velocity greater than the critical one, u_0 , leads to chemical change. There must also be a definite orientation of the molecules with respect to one another at the moment of collision. This consideration holds especially for complex molecules, which may be capable of reacting only at one end. The collision theory is thus considerably less precise than may at first have appeared.

Application of kinetic molecular theory to a simple bimolecular reaction (e.g., the decomposition of hydrogen iodide) leads to equation (25), which relates the rate constant, k , with u_0 , the minimal velocity at collision, necessary for reaction.

$$k = \frac{4N^2d^2}{\sigma^2} \sqrt{\frac{\pi RT}{m}} \left(1 + \frac{mu_0^2}{2kT}\right) e^{-mu_0^2/2kT} \quad (25)^1$$

$$\frac{1}{\sigma} = \frac{1}{m_1} + \frac{1}{m_2} \quad (26)$$

Here N molecules of effective diameter d and weight m are present at a concentration of c moles per litre and at an absolute temperature T . The symbol σ is the base of the system of natural logarithms, and k is Boltzmann's constant, 1.38×10^{-16} ergs/degree. If the values of k are experimentally determined for a series of temperatures, the values of both u_0 (the minimal velocity of one molecule relative to another required for effective collisions) and of d (the effective diameter of the particles) can be determined. The difficulties previously discussed then appear as anomalously large or small values of d^2 . That is to say, when the reacting particles attract each other, the cross sections of the molecules (proportional to d^2) which are "effective" for collisions, will be large compared to these cross sections as determined by other methods; conversely, when the particles repel one another, or when a preferred orientation is necessary for reaction, the "effective" cross section will be small. The latter condition holds (although not to a marked degree) for the hydrogen iodide reaction.

An alternative description of the reaction process may be obtained by computing a collision number on the basis of the best available estimates for molecular cross sections and by replacing equation (25) by (27), to which it is approximately equivalent.

$$k = PZe^{-Q/RT} \quad (27)$$

Here Z is the "normal" collision factor, P is the "probability" factor defined by equation (27), and Q is the activation energy which does not differ greatly from $\frac{1}{2}Mu_0^2$, where M is the molecular weight of the substance in question. The difficulties of the collision theory are then contained in the factor P , and the problem of obtaining precise agreement between theory and experiment is reduced to that of computing P correctly.

One additional aspect of collision theory deserves attention. Some reactions (as previously stated) are of the first order. Such reactions would seem to be independent of collisions. In what way can these reactions be correlated with collision theory? Some first-order reactions probably cannot be so correlated. The disintegration of radium is strictly of the first order; the rate of the

¹ If the two molecules which react are not identical, this expression must be somewhat modified. Among other modifications, the reduced mass μ replaces m . If the masses of the two molecules in question are m_1 and m_2 , then the reduced mass μ is defined by equation (26).

reaction depends upon changes in the radium nucleus, which are unaffected by collisions of the molecule as a whole. But in ordinary chemical, as opposed to nuclear, reactions, the energy necessary for reaction is probably acquired by the decomposing molecule through previous collisions.

The Activated-Complex Theory.—An alternative general theory of reaction kinetics is formulated in terms of the so-called "activated complex." (S. A. Arrhenius, J. N. Brønsted, N. Bjerrum, H. Eyring). In this theory, it is assumed that all the reactants are in pseudoequilibrium with an activated complex, X,

which in turn decomposes to give the reaction products. The activated complex X is not a true molecule; it is merely a stage in the process by which the reactants become the reaction products. Hence, the activated complex is not in true equilibrium with the reactants. The activated-complex theory, however, is founded on the assumption that the concentration of the activated complex may be computed just as if it were a real, stable chemical compound. The rate of reaction is then the product of the concentration of X multiplied by the rate at which it decomposes. This rate can be computed by the general methods of quantum mechanics (g, v); it is the same for all activated complexes, regardless of the materials out of which they have been formed. For a reaction such as (23), the activated-complex theory leads to equation (29)

$$v = \frac{kT}{h} K^* (A)^a (B)^b (C)^c \dots \frac{\gamma_A \gamma_B \gamma_C}{\gamma_X} \quad (29)$$

where k is the Boltzmann constant, h is Planck's constant, K^* is the equilibrium constant for the formation of the activated complex (its decomposition into the reaction products being disregarded), and $\gamma_A, \gamma_B, \gamma_C, \dots, \gamma_X$ are respectively the activity coefficients of the reactants and of the activated complex. The constant κ is called the transmission coefficient; it is usually nearly unity. When the activated-complex theory is used to describe a reversible reaction, a distinction must be drawn between the activated complex formed from the reactants and that formed from the reaction products. The two complexes, although structurally the same, differ with respect to the materials from which they have been formed and into which they are decomposing. Unless the distinction in question is made, the theory is self-contradictory.

Equation (29) contains γ_X , the activity coefficient for the activated complex. Although this coefficient cannot be measured (since the activated complex is not a stable entity) it can be estimated for the complexes which occur in ionic reactions. The charge on the activated complex must be the sum of the charges on the reactants; furthermore, the charge on an ion, as a first approximation, determines its activity coefficient. Equation (29) correctly predicts the rates of ionic reactions; it leads to results identical with those obtained by Christiansen. Although in particular instances the collision theory may be more convenient to apply than is the activated complex theory, or vice versa, the two always lead to the same results; they are, in essence, two different languages in which the same phenomena may be described.

At equilibrium, the rates of the forward and reverse reactions are equal. When two rate expressions analogous to (29) are used, an equation (30) is obtained from which the activity coefficient of the activated complex and the transmission coefficients have been eliminated.

$$\frac{(R)^a (S)^b (T)^c \dots (\gamma_R)^a (\gamma_S)^b (\gamma_T)^c \dots}{(A)^a (B)^b (C)^c \dots (\gamma_A)^a (\gamma_B)^b (\gamma_C)^c \dots} = K \quad (30)$$

Here K is the true thermodynamic equilibrium constant, expressed in terms of activities (concentrations multiplied by activity coefficients).

The pseudoequilibrium constant, K^* , of equation (29) is related to the free energy of activation, ΔF^* , the heat of activation ΔH^* , and the entropy of activation ΔS^* , by equation (31).

$$-RT \log_e K^* = \Delta F^* = \Delta H^* - T \Delta S^* \quad (31)$$

The heat of activation, ΔH^* , corresponds roughly with the energy of activation, Q , of the collision theory; the entropy of activation, ΔS^* , may be roughly related to the logarithm of the "probability"

factor, P , of equation (27).

The thermodynamic concept of entropy has been interpreted, through statistical mechanics, in terms of molecular vibrations. Likewise, entropy of activation can often be interpreted in terms of the geometry and of the estimated vibrational frequencies of the activated complex.

The application of the activated-complex theory depends upon the computation of the pseudoequilibrium constant, K^* . Thus, the kinetic problem is replaced by a thermodynamic one, and all the powerful tools of thermodynamics and of statistical mechanics become immediately available for its solution. It is possible in principle (always) and in practice (occasionally) to calculate the rate of a chemical reaction without the use of any experimentally determined kinetic data. The difficulties reside principally in the selection of appropriate constants for the activated complex. For the reaction between a hydrogen atom and a hydrogen molecule (which has been investigated by the use of ortho- and parahydrogen and of deuterium), the absolute reaction rate has been computed by methods related to the activated-complex theory (E. Wigner). Most reactions are, however, too complex for complete mathematical solution by methods now known.

READE, CHARLES (1814–1884), English novelist and dramatist, the son of an Oxfordshire squire, was born at Ipsden, Oxfordshire, on June 8, 1814. He entered Magdalen college, Oxford, proceeded B.A. in 1835, and became a fellow of his college. He was subsequently dean of arts, and vice-president of Magdalen college, taking his degree of D.C.L. in 1847. His name was entered at Lincoln's Inn in 1836; he was elected Vinerian fellow in 1842, and was called to the bar in 1843. He kept his fellowship at Magdalen all his life, but after taking his degree he spent the greater part of his time in London. He began as a dramatist, and it was his own wish that "dramatist" should stand first in the description on his tombstone.

His first comedy, *The Ladies' Battle*, appeared at the Olympic theatre in May 1851. It was followed by *Angelo* (1851), *A Village Tale* (1852), *The Lost Husband* (1852) and *Gold* (1853). But Reade's reputation was made by the two-act comedy, *Masks and Faces*, in which he collaborated with Tom Taylor. It was produced in Nov. 1852, and later was expanded into three acts. By the advice of the actress, Laura Seymour, he turned the play into a prose story which appeared in 1853 as *Peg Woffington* as did also *Christie Johnstone*, a study of Scottish fisher folk. In 1854 he produced, with Tom Taylor, *Two Loves and a Life* and *The King's Rival*; and, unaided, *The Courier of Lyons*—well known under its later title, *The Lyons Mail*—and *Peregrine Pickle*. In 1855 appeared *Art*, afterward known as *Nance Oldfield*.

He made his name as a novelist in 1856, when he published *It's Never Too Late to Mend*, a novel written with the purpose of reforming abuses in prison discipline and the treatment of criminals. Five minor novels followed in quick succession—*The Course of True Love Never Did Run Smooth* (1857), *Tack of All Trades* (1858), *The Autobiography of a Thief* (1858), *Love Me Little, Love Me Long* (1859), and *White Lies* (1860), dramatized as *The Double Marriage*. In 1861 his masterpiece, *The Cloister and the Hearth*, appeared, relating the adventures of the father of Erasmus. It is one of the finest historical novels in existence. Returning from the 15th century to modern English life, he produced another novel with a purpose, *Hard Cash* (1863), in which he directed attention to the abuses of private lunatic asylums. Three other novels "with a purpose" were *Foul Play* (1866), in which he exposed the iniquities of ship-knackers, and paved the way for the labours of Samuel Plimsoll; *Put Yourself in His Place* (1870), in which he grappled with the trade unions; and *A Woman-Hater* (1877), on the degrading conditions of village life. *The Wandering Heir* (1875), of which he also wrote a version for the stage, was suggested by the Tichborne trial.

Outside the line of these moral and occasional works Reade produced three elaborate studies of character—*Griffith Gault* (1866), *A Terrible Temptation* (1871), *A Simpleton* (1873). The first of these was in his own opinion the best of his novels. His greatest success as a dramatist attended his last attempt—*Drink*—an adaptation of Zola's *L'Assommoir*, produced in 1879. In that year his friend Laura Seymour, who had kept house for him since 1854, died. Reade's health failed from that time, and he died on April 11, 1884, leaving behind him a completed novel, *A Perilous Secret*, which showed no falling off in the arts of weaving a complicated plot and devising thrilling situations. Reade was an amateur of the violin, and among his works is an essay on Cremona violins with the title, *A Lost Art Revived*.

It was characteristic of Reade's open and combative nature that he admitted the public freely to the secrets of his method of composition. By his will he left his workshop and his accumulation of materials open for inspection for two years after his death. He had collected an enormous mass of materials for his study of human nature, from personal observation, from newspapers, books of travel, blue books of commissions of inquiry, and from miscellaneous reading. This vast documentation, and Reade's use of it, show him as a precursor of the school of Zola. The collection was classified and arranged in huge ledgers and notebooks. He had planned a great work on "the wisdom and folly of nations," dealing with social, political and domestic details, and it was chiefly for this that his collection was destined, but in passing he found the materials useful as a store of incidents and suggestions. A collector of the kind was bound to be systematic, otherwise his collection would have fallen into confusion, and Reade's collection contains many curiosities in classification and tabulation. On the value of this method for his art there has been much discussion, the prevalent opinion being that his imagination was overwhelmed and stifled by it. He himself maintained the contrary; and it must be admitted that a priori critics have not rightly understood the use that he made of his laboriously collected facts. He did not merely shovel the contents of his notebooks into his novels; they served rather as an atmosphere of reality in which he worked, so that his novels were like pictures painted in the open air. His imagination worked freely among them and was quickened rather than impeded by their suggestions of things suited to the purpose in hand; and it is probably to his close and constant contact with facts, acting on an imagination naturally fertile, that we owe his marvelous abundance of incident. Even in his novels of character there is no meditative and analytic stagnation; the development of character is shown through a rapid unceasing progression of significant facts. This rapidity of movement was perhaps partly the result of his dramatic studies; it was probably in writing for the stage that he learned the value of keeping the attention of his readers incessantly on the alert. The hankering after stage effect, while it saved him from dullness, often betrayed him into rough exaggeration, especially in his comic scenes. But the gravest defect in his work is a defect of temper. His view of human life, especially of the life of women, is almost brutal; his knowledge of frailties and vices is obtruded with repellent force; and he cannot, with all his skill as a story-teller, be numbered among the great artists who warm the heart and help to improve the conduct. But as a moral satirist, which was the function he professed over and above that of a story-teller, he did good service, both indirectly in his novels and directly in his own name.

READING, RUFUS DANIEL ISAACS, 1ST MARQUESS OF (1860-1935). British statesman, was born on Oct. 10, 1860, in London, the second son of Joseph Isaacs, merchant. He was educated at University college school, London, and abroad. At the age of 14 he ran away to sea, and served two years before the mast in a sailing ship. A subsequent venture on the stock exchange was a failure. He then read for the bar,

and was called in 1887; the same year he married Miss Alice Cohen. His legal career was unbroken and successful.

He entered parliament as a Liberal Imperialist, winning a seat for his party at Reading in a by-election in 1904, which he retained until he went to the House of Lords. His party had the highest opinion of him and he became attorney-general in 1910, and in 1912 was given a seat in the cabinet, which no attorney-general had held before. Then followed the great Marconi shares scandal, in which he and Lloyd George were alleged to be involved. The substance of the charge was that he had bought American Marconi shares, some of which he sold to Lloyd George, while the British Marconi company was contracting with the government. It was investigated by a committee of the house and his reputation was certainly vindicated. On Oct. 20, 1913, he was made lord chief justice, and in Jan. 1914, was created Baron Reading of Erleigh. In this office he distinguished himself by humanity in the conduct of criminal cases and by the establishment of the principle that the court of criminal appeal should act as a real court of revision, upsetting verdicts or reducing sentences even of the individual high court judges. He presided over the trial of Casement in Ireland during World War I.

After the outbreak of the war in Aug. 1914, he assisted in the drafting and the administration of those measures which saved England from financial ruin. The most sensational of these was the granting of the British guarantee to the great accepting houses, to bills amounting to many hundred millions of pounds. In 1915 he was president of the Anglo-French Loan commission to the United States, where he succeeded in floating a great war loan. On June 26, 1916, he was created Viscount Reading of Erleigh.

In 1917 he was appointed high commissioner and special envoy to the United States, and in December of that year was created an earl. In 1918 he was appointed high commissioner and special ambassador at Washington.

Lord Reading's term as viceroy of India began at the end of World War I. He was faced immediately by four acute problems. First the diarchy system of the Montagu-Chelmsford Government of India act, devised as a step in advance toward complete self-government, was definitely rejected by the leaders of the united Hindu and Mohammedan educated population, who in the movement known as Swaraj had resolved to make it unworkable. The second was the influence of Mahatma Gandhi, one of the most remarkable men of all time, who had inflamed millions of Indians to a boycott of the west by the east and a kind of gigantic movement of passive resistance, in which both British products and British government were to be alike rejected. The third was that the national temper of India had been aroused by prohibitions and indignities put upon Indians in other parts of the empire. The fourth, the story of the Punjab rebellion and the slaughter at Amritsar in 1919, with the support of Gen. Dyer's action there by the governing classes in England, had excited a feeling of such fierce resentment throughout the length and breadth of the peninsula as might have caused a general uprising. In dealing with the revolt against the diarchy, he was compelled to imprison the two Mohammedan leaders, the brothers Ali. And although he was able to establish some kind of self-government in most of the local provinces and even something like friendly co-operation in the Central Legislative council the constitution broke down in the central provinces and had to be suspended in Bengal, with a return to complete autocratic government. In the case of the boycott of the west the viceroy, after attempts at reconciliation with Gandhi, authorized his prosecution for inciting to mass civil disobedience which resulted in a sentence of six years' imprisonment, although the mahatma was released on the grounds of ill-health after two years.

Upon Lord Reading's return to England in April 1926 he was created a marquess. He was secretary of state for foreign affairs, Aug.-Nov. 1931. He died Dec. 30, 1935. (See INDIA: History.)

See G. R. Reading, *Rufus Isaacs, First Marquess of Reading* (1942).

READING, a county and parliamentary borough and the county town of Berkshire, England, 36 mi. W. by S. of London by railway. Pop. (1951) 114,176; area 14 sq.mi.

to Philadelphia in 1824 (abandoned in 1922), the Union canal to Lebanon and Middletown in 1828 (abandoned about 1880) and the Philadelphia and Reading railway in 1838. A company of Reading and Berks militiamen was the first unit to report to General Washington at Cambridge in response to the call for troops by the second continental congress; and the Ringold light artillery (later known as "the First Defenders"), largely recruited from Reading and Berks county, was the first volunteer company to reach the national capital when Lincoln called for troops.

READYMONEY, SİR COWASJI JEHANGIR (1812-1878), "the Peabody of Bombay." Early in the 18th century three Parsee brothers moved from Nowsari, near Surat, in Gujarat to Bombay, and became the pioneers of a lucrative trade with China. They gained the sobriquet of "Readymoney," which they adopted as a surname. Only Hirji Jevanji Readymoney left issue, two daughters, the elder of whom married a Banaji, and the younger a Dady Sett. The son of the former, Jehangir Hirji, married Mirbae, the daughter of the latter, and was made the heir not only of his grandfather, but of his two granduncles.

The younger of their two sons was Cowasji Jehangir. His only English education was at the then well-known school kept by Serjeant Sykes in the fort of Bombay.

At the age of 15 he entered the firm of Duncan, Gibb and company, as "godown keeper," or warehouse clerk. In 1837 he was promoted to the responsible and lucrative appointment of guarantee broker to two of the leading European firms of Bombay.

In 1846 he began trading on his own account. He was made a J.P. for the town and island of Bombay, and a member of the board of conservancy, and in 1866 was appointed a commissioner of income tax. His tactful management was largely responsible for the fact that this tax, then new to Bombay and unpopular, was levied with unexpected financial success.

He was made C.S.I. in 1871, and in 1872 K.B. His donations to the institutions of Bombay amounted to nearly £200,000.

See *J. Cowasji Jehangir, Sir Cowasji Jehangir Readymoney* (1890).

REAGAN, JOHN HENNINGER (1818-1905), U.S. politician, was born in Sevier county, Tennessee, on Oct. 8, 1818. He removed to Texas in 1839, was admitted to the bar in 1846, and in 1857-61 was a representative in congress. His political views were determined by the ultrademocratic influence of Andrew Jackson and the state-sovereignty philosophy of John C. Calhoun. In 1861 he was appointed postmaster general in Pres Jefferson Davis's cabinet, and served in this capacity throughout the Civil War. He was captured with the Davis party on May 10, 1865, and was imprisoned in Ft. Warren, Boston harbour, until the following October. While in prison he wrote the "Fort Warren letter" (Aug. 11), in which he urged the people of Texas to recognize their defeat, grant civil rights to the freedmen, and try to conciliate the North. From 1875 to 1887, when he entered the U.S. senate, he was again a representative in congress. In 1891, believing that his first duty was to his state, he resigned from the senate to accept the chairmanship of the newly established state railway commission. In 1901 he retired from public service. He died at Palestine, Tex., on March 6, 1905.

See his *Memoirs, with Special Reference to Secession and the Civil War*, edited by W. F. McCaleb (1906).

REALF, RICHARD (1834-1878), U.S. abolitionist and poet, was born on June 14, 1834, at Framfield, Sussex, Eng. The son of a rural constable, he began to write poetry at an early age, and, sponsored by a group of literary patrons including Samuel Rogers, he published *Guests at the Beautiful* (1852).

In 1854 Realf went to the United States; he worked at the Five Points House of Industry, New York city, until 1856, when he became a newspaper correspondent in the west. In May 1858 Realf was a delegate to the convention held by the abolitionist John Brown at Chatham, Can. Later in the same year he went to England, remaining there until 1859. Although he did not take part in the abolitionists' attack on the arsenal at Harpers Ferry, W.Va., in Oct. 1859, Realf was arrested for complicity and questioned by a senate investigating committee. During the Civil War he served with the 88th Illinois regiment and after the war with a Negro regiment in the south. In 1872 he began working as a newspaper

man and lecturer in Pittsburgh, Pa., but by 1877 he had become almost completely blind. In July 1878 he went to San Francisco, Calif., where he worked as a labourer. He took a fatal dose of poison in a hotel in Oakland, Calif., on Oct. 28, 1878. Married in 1865 to Sophia Emery Graves, from whom he was never divorced, Realf was also married in 1867 to Catherine Cassidy, from whom he was divorced in 1873. After his marriage to a third wife, by whom he had four children, his second wife had the divorce decree set aside. In 1898 his *Poems* was published.

REALGAR, a mineral species consisting of arsenic monosulphide, AsS, and occurring as monoclinic crystals of a bright red colour. There is a perfect cleavage parallel to the plane of symmetry; hardness is 5-2, specific gravity 3.55. On exposure to light the crystals crumble to a yellow powder. The mineral usually occurs with ores of silver and lead in mineral veins. Realgar has been used as a pigment and in pyrotechny for producing a brilliant white fire; but it is now replaced by the artificially prepared compound. The other native arsenic sulphide, As₂S₃, is known as orpiment. (L. J. S.)

REALISM, a philosophical term used in two opposite senses. The older of these is the scholastic doctrine that universals have a more "real" existence than things. Universals are, in scholastic language, *ante res*, *in rebus* and *post res*. In the most extreme form realism denies that anything exists in any sense except universals. It is opposed to nominalism (*q.v.*) and conceptualism (*q.v.*). For the history of the doctrine, see SCHOLASTICISM. In this sense, realism has been called "an assertion of the rights of the subject" and some part of the teaching of Socrates concerns itself with the scholastic doctrine of realism. The modern application of the term is to the opposing doctrine that there is a reality apart from its presentation to consciousness. In this sense it is opposed to idealism (*q.v.*), whether the purely subjective or that more comprehensive idealism which makes subject and object mutually interdependent. In its crude form it is known as "Natural" or "Naïve" Realism. It appears, however, in more complex forms, e.g., as Ideal Realism (or Real Idealism), which combines epistemological idealism with realism in metaphysics. Again, Kant distinguishes "empirical" realism, which maintains the existence of things in space independent of consciousness, from "transcendental" realism, which ascribes absolute reality to time and space. (See PHILOSOPHY, HISTORY OF.)

In literature and art "realism" again is opposed to "idealism" in various senses. The realist is (1) he who deliberately declines to select his subjects from the beautiful or harmonious, and, more especially, describes ugly things and brings out details of an unsavoury sort; (2) he who deals with individuals, not types; (3) most properly, he who strives to represent the facts exactly as they are.

REALITY: see LOGIC; ONTOLOGY.

REAL PRESENCE: see TRANSUBSTANTIATION and EUCCHARIST.

REAL PROPERTY AND CONVEYANCING: see LAWS RELATING TO REAL PROPERTY AND CONVEYANCING.

REAPING, the cutting of ripe grain, began as soon as prehistoric man grew crops. By the late stone age his rudimentary sickle consisted of three saw-toothed flint blades set in a straight wooden shaft about 2 ft. long. Among artifacts of Europe and England are curved flint knives whose shape suggests that they were sickles or reaping hooks. Bronze sickles of various shapes were also common among later remains. The tomb paintings (c. 1400 B.C.) at Thebes, Egypt, include the oldest pictorial record of reaping. This painting shows that the grain was either cut low, a handful at a time, and then bound into sheaves or pulled up by the roots and the heads stripped off with a hackle. The Egyptian sickles were made of bronze or iron. The early form consisted of a slightly curved blade fastened at one end to a straight handle; a later type had a serrated blade shaped more nearly like a modern sickle.

Although variants of the Egyptian sickle were used by the Babylonians, Assyrians, Hebrews, Greeks and Romans, the latter were the first to develop the two-handed scythe, which they used only for mowing. Varro described three ways of reaping in his

Rerum rusticarum (37 B.C.): the grain was cut close to the ground with a sickle and bound in sheaves; it was cut halfway down the stalk and laid in a swath; or the heads were stripped from the stalks leaving the straw standing. A special device, the header, was used for this operation.

Both Pliny and Palladius described the header as a Gallic invention, consisting of a two-wheeled cart with a saw-toothed blade set across the open front. As an ox pulled the cart, the teeth adjusted to the height of the grain stripped the heads from the stalks, and they fell into the cart. The straw was cut later. The header was important as the first of a long series of attempts to lessen the labour and time involved in reaping.

Throughout the middle ages reaping continued to be done with sickle and scythe, but both implements were improved in design and material. An intermediate form, the Hainault scythe, was a Flemish invention. It was a wide blade about 2 ft. long attached to a short handle. Although more efficient than a sickle, it was surpassed by the later forms of the scythe. The most important improvement in the scythe was the addition of the cradle to lay the cut grain in a swath. Although the date of origin is unknown, Thomas Tusser mentioned a barley cradle in 1557. The colonists brought the cradle to America, where it reached its ultimate form—a frame of five tapering wooden fingers paralleling the blade and attached to the snath of the scythe. With a cradle, grain could be cut much faster than with the sickle, so that reaping with the sickle was finally abandoned. However, the sickle and scythe are still used on small, hilly fields throughout the world.

The modern reaper was developed gradually and simultaneously on both sides of the Atlantic. In Europe there was no progress until a deliberate attempt was made to stimulate agricultural inventions. The demand for grain grew with increased population, and agriculture had to compete with industry for labour. Consequently there was an increasing need for machinery to replace the disappearing migratory harvest hands. At the same time rural labour was deeply prejudiced against reapers. In America, where there had always been a labour shortage, the development of the great wheat-growing areas depended on the invention of a satisfactory mechanical reaper, and the U.S. Civil War hastened its adoption because the drain of manpower to the army made mechanical reaping imperative.

English Contributions.—When the London, England, Society of Arts offered a gold medal for the introduction of a reaping machine in 1780, Capel Loft brought forth Pliny's and Palladius' accounts of the Gallic header and suggested certain improvements in the simple mechanism. Following this same idea, William Pitt of Pendeford, England, in 1786 constructed a header with a revolving cylinder armed with rows of teeth that caught the heads and dropped them into the box of the machine. Like its Roman prototype, Pitt's machine was pushed through the grain. The header, however, was a failure, and nothing further was done with the design in England.

The first English patent for a reaper was taken out by Joseph Boyce in 1799. His machine had a revolving knife protected by guards but no reel and no device for laying the cut grain in gables or in a swath. As invention followed invention, first one feature and then another was tried, so that a shear-action cutter, elementary dividers and fingers, a simple reel, a platform consisting of an endless apron with rollers, a main wheel to support the weight of the machine, and pulling instead of pushing had all been experimented with before Henry Ogle constructed his reaper in 1822. It was drawn from the front and side and carried on two main wheels. The cutter consisted of a straight-edged knife blade. The reel, resembling the modern form, pushed the grain back upon a platform behind the cutter. The platform was hinged so that it could be tilted and serve as a dropper. Although Ogle's machine never became popular, his principle of the cutter and reel was adopted in all subsequent successful designs.

In 1826 Patrick Bell, a Scottish minister, invented a reaper with a shear-action cutter. Twelve movable blades about 15 in. long and 4 in. wide at the base, fastened on pivots, moved back and forth over 13 stationary blades of about the same size and

produced a clipping movement like that of shears. The cut grain fell upon an endless apron that carried it to the side and deposited it in a continuous swath. The model had a reel and dividers and was pushed, not pulled. Bell's reaper remained the most important English contribution but received little attention until U.S. designs were taken to England in 1851.

U.S. Contributions.—Although the first U.S. patent was granted in 1803, no machine of any importance was patented until 1822, when Jeremiah Bailey brought out a model that was both mower and reaper. The revolving cutter was shaped like a low-crowned hat, the knife being the edge of the brim. A shoe regulated the distance of the knife from the ground and was the first indication of the principle of a flexible bar. The next invention worthy of mention was that of William Manning in 1831. His cutter bar, made up of spear-shaped cutters sharpened on both edges, reciprocated over guard teeth 6 in.-8 in. long. The machine also had a divider, the first on record in America. Manning's cutter anticipated the designs used by Hussey and McCormick.

Obed Hussey and Cyrus H. McCormick experimented with their reapers simultaneously, but McCormick had his at work by 1831. Hussey, however, was the first to secure a patent—on Dec. 31, 1833. Hussey's machine was fairly simple in construction. Back of the two ground wheels and to the side was the platform supported by a roller. The cutter, original in design, had slotted fingers or guards about 8 in. long fixed solidly to the front edge of the platform. Through these vibrated a number of flat triangular knives riveted to an iron bar, thus forming a coarse-toothed saw.

McCormick's machine, patented the next year, was more complicated and not so well built. A single drive wheel furnished the power for the reciprocating knife. The knife, about 43 ft. long with a smooth or serrated edge, oscillated through wires designed to act as fingers to hold the grain. Behind this was a platform 5 ft.-6 ft. long made of thin plank from which the cut grain was raked by a man walking behind the machine. A cloth-covered frame served as a divider to separate the cut from the uncut grain. A revolving reel, 6 ft.-7 ft. in diameter and as long as the knife, was fastened over the cutter. The cutters in both these machines represented the new element added to reaper design. Neither functioned very well at first as they had a tendency to clog, but subsequent improvements obviated this difficulty. In 1851 both men sent models to England, where their performance was acclaimed.

As soon as a successful reaper had appeared on the market, inventors turned their attention to providing an automatic device that would deliver the cut grain in a form suitable for binding; thus the self-rake and the dropper were next added to the reaper. From 1850 to 1870 the self-raking reaper held the field, but by the middle 1870s the self-rakes in turn were being replaced by harvesters.

The main difference between harvesters and reapers is that the former include special mechanisms to handle and bind the cut grain into sheaves or bundles ready to be set up in shocks. The early attempts to produce machines that would bind as well as reap were very crude, and the actual binding with straw, wire or twine still had to be done by hand. C. W. and W. W. Marsh patented the first successful harvester in 1858. A canvas delivered the cut grain over the drive wheel to a box from which it was taken and bound by two men riding on the machine. This change in design set the pattern for future harvesters. However, a successful binding mechanism was still lacking. Because twine was very expensive, the first binders used wire, but the farmers and millers complained so much about the damage to cattle and machinery that these binders never became popular. John F. Appleby made a successful twine binder in 1858, but it was not put on the market until 1880, when the price of twine was sufficiently low to make its use economical. Thus the McCormick cutting principle, the Marsh frame and the Appleby binder were combined to produce the successful modern harvester.

The header, also belonging to the harvester class, was developed in the United States, Canada and Australia, where the weather

permits grain to stand a considerable time after ripening. As early as 1844, George Esterly patented a header that worked very well, and a few were manufactured. The following year in Australia a header was invented that cut and threshed the grain in one operation. The Haines Illinois harvester, patented in 1849, was widely used in the United States until it was replaced by better types of harvesters.

Combined harvesters and threshers are used wherever the threshed grain is dry enough to store. On large wheat farms a huge combine can head, thresh, separate and sack the grain from 60 ac. to 725 ac. per day, or about 1,700 bu. to 3,000 bu. Before tractors were available these combines were propelled either by steam engines or horses. For smaller farms in the Great Plains of the United States, the "baby" combine, cutting a 5-ft. or 6-ft. swath and operated by one man, was introduced in 1935. By the 1940s a "midget" combine, cutting only a 40-in. swath, was being used by small farmers to lower harvest costs. (See also HARVESTING MACHINERY.)

REAR VAULT in architecture, a vault supporting the thickness of the wall inside a window or door opening, usually with a splayed or sloped surface, and often laid out upon a different curve from that of the arch over the window or door itself. In Gothic architecture, especially in England, the rear vault is usually decorated at its inner edge by a projecting rib known as a scolinson rib, which is itself often supported by colonnettes known as scolinson shafts, at the inner edges of the opening.

REASON, in philosophy, the faculty or process of drawing logical inferences. Thus we speak of man as essentially a rational animal, it being implied that man differs from all other animals in that he can consciously draw inferences from premises. It is, however, exceedingly difficult in this respect to draw an absolute distinction between men and animals, observation of which undoubtedly suggests that the latter have a certain power of making inferences. Between the higher animals and the lower types of mankind the distinction is so hard to draw that many psychologists argue that the difference is one of degree rather than of kind (see *INSTINCT*). There is little doubt, however, that inference by man differs from that of the brute creation in respect of self-consciousness, and, though there can be no doubt that some animals dream, it is difficult to find evidence for the presence of ideas in the minds of the lower animals. In the nature of the case satisfactory conclusions as to the rationality which may be predicated of animals are impossible.

The term "reason" is also used in several narrower senses. Thus reason is opposed to sensation, perception, feeling, desire, as the faculty (the existence of which is denied by empiricists) by which fundamental truths are intuitively apprehended. These fundamental truths are the causes or "reasons" (*αἰτια*) of all derivative facts. With Kant, reason (*Vernunft*) is the power of synthesizing into unity, by means of comprehensive principles, the concepts provided by the intellect (*Verstand*). The reason which gives *a priori* principles Kant calls "Pure Reason," as distinguished from the "Practical Reason" which is specially concerned with the performance of actions. In formal logic the drawing of inferences (frequently called "ratiocination," from Lat. *ratiocinari*, to use the reasoning faculty) is classified from Aristotle downwards as deductive (from generals to particulars) and inductive (from particulars to generals); see *LOGIC, INDUCTION, SYLLOGISM*. In theology, reason, as distinguished from faith, is the human intelligence exercised upon religious truth whether by way of discovery or by way of explanation. The limits within which the reason may be used have been laid down differently in different churches and periods of thought; on the whole, modern Christianity, especially in the Protestant churches, tends to allow to reason a wide field, reserving, however, as the sphere of faith the ultimate (supernatural) truths of theology.

The Greek words for reason are *νοῦς* and *λόγος*, both vaguely

used. In Aristotle the *λόγος* of a thing is its definition, including its formal cause, while the ultimate principles of a science are *ἀρχαί*, the "reasons" (in a common modern sense) which explain all its particular facts. *Νοῦς* in Plato and Aristotle is used both widely for all the meanings which "reason" can have, and strictly for the faculty which apprehends intuitively. Thus, in the *Republic*, *νοῦς* is the faculty which apprehends necessary truth, while *δόξα* (opinion) is concerned with phenomena.

The Schoolmen distinguished between *ratio cognoscendi* (a reason for acknowledging a fact) and *ratio essendi* (a reason for the existence of this fact).

RÉAUMUR, RENÉ ANTOINE FERCHAULT DE (1683-1757), French scientist, was born on Feb. 28, 1683, at La Rochelle, where he received his early education. In 1703 he came to Paris, where he continued the study of mathematics and physics, and in 1708 was elected a member of the Académie des Sciences. In 1710 he was charged with the official description of the useful arts and manufactures of France, which led him to many practical researches that resulted in the establishment of new manufactures and the revival of neglected industries. For discoveries regarding iron and steel he was awarded a pension of 12,000 livres; but he requested that the money should be secured to the Académie des Sciences for the furtherance of experiments on improved industrial processes. In 1735 family arrangements obliged him to accept the post of commander and intendant of the royal and military order of Saint-Louis; he discharged his duties with scrupulous attention, but declined the emoluments. Réaumur died at La Bermondière, Maine, on Oct. 17, 1757. He bequeathed his manuscripts, which filled 138 portfolios, and his natural history collections to the Académie des Sciences.

Réaumur's papers dealt with nearly all branches of science. He examined and reported on the auriferous rivers, the turquoise mines, the forests and the fossil beds of France. He devised the method of tinning iron that is still employed, and investigated the chemical differences between iron and steel. His book on this subject (1722) was translated into English and German. The thermometric scale by which he is now best remembered was constructed on the principle of taking the freezing-point of water as 0°, and graduating the tube of the thermometer into degrees each of which was one-thousandth of the volume contained by the bulb and tube up

to the zero mark. It was an accident dependent on the coefficient of expansion of the particular quality of alcohol employed which made the boiling-point of water 80° R.; and mercurial thermometers the stems of which are graduated into eighty equal parts between the freezing- and boiling-points of water are Réaumur thermometers in name only. Réaumur wrote widely on natural history, his best known work on this subject being the *Mémoires pour servir à l'histoire des insectes* (6 vols., 1734-42).

REBAB or **RABAB**, an ancient stringed instrument, sometimes plucked and sometimes played with a bow, having a body either pear-shaped or boat-shaped and the characteristics of vaulted

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

AN ARABIAN REBAB AND BOW

back and the absence of neck; also a generic modern Arabic term applied by the Mohammedans of northern Africa to various stringed instruments played with a bow. The rebab exercised a very considerable influence on the history of stringed instruments in Europe, and was undoubtedly the means through which the bow was introduced to the West, though whether it may be accepted as the ancestor of the violin, as is held by some, is another matter.

The bowed instruments of the middle ages fall naturally into

two distinct classes, according to the principles observed in construction. One is the type having a body formed on the model of a Greek or a Roman cithara, with back and sound board connected by ribs, from which it was evolved by the addition of a neck and finger-board (see GUITAR and GUITAR FIDDLE). The other is the type derived from the Eastern rebab, with vaulted back attached directly to the sound board, which has never attained to any serious artistic development.

For the European development of the rebab, see REBEC.

REBATES, DEFERRED. A deferred rebate is a discount on the invoice price returned after a lapse of time to a trader, on certain conditions, as a means of maintaining monopoly and keeping out would-be competitors from the trade. The system is in use in many branches of British trade and industry. It consists in returning to the trader (merchant or retailer) at the end of every six or 12 months a rebate equal to perhaps 10 or 15% on his purchases, on condition that he shall not, during the period, have sold, displayed (or, it may be, offered) any of the kind of goods produced by the combination except those made by the combination. The effect of the arrangement is that if at any time during that period the customer is offered an article of better value by an outside maker or by a new firm starting in the industry, the buying of that article will cost him anything from one to 12 months' accumulated rebates on his association purchases and may result in his being placed on the association's "black list," which means that he shall not again be supplied with association goods except at prices which will yield an insufficient profit on resale. The reasons advanced by combinations for the use of the deferred rebate are not altogether reasons of monopoly. They contend that steadiness and continuity of custom are essential to economical manufacture; that by maintaining an even level of prices (which, as the market fluctuates, may be temporarily under-profitable as sometimes over-profitable) they are serving the best interest of the customer; and that these mutual advantages cannot be secured if the customer is left free to trade with the combination when its prices are below average, and go elsewhere when they are above. The most notable example of the use of the deferred rebate is to be found in the case of the shipping companies operating liner services, where the fluctuating competition of the "tramp" and the great importance of securing a steady volume of freights if a regular service is to be maintained lend particular weight to the arguments quoted above. In the manufacturing industries there is less agreement among members of combinations as to the advantage of the deferred rebate, and instances have occurred of the system being voluntarily abandoned. (J. H.)

REBEC or REBECK, a mediaeval stringed instrument played with a bow, derived from the Oriental rebab, and sometimes regarded as the ancestor of the viol and violin. Like the rebab (*q.v.*), the rebec assumed at first one of two forms—the pear-shaped body with a wide base, strung with three strings, or the long, narrow pear- or boat-shaped body with two strings and, in addition, the other Oriental characteristics of the rebab, *i.e.*, the vaulted back, the absence of ribs, and pegs set in the back of the head. Except for the addition of a fingerboard, what is now recognized as the rebec underwent no structural development and never entered the domain of art, despite the wide favour which it enjoyed throughout the middle ages.

REBECCA RIOTS, the name given to some disturbances which occurred in 1843 in South Wales. The rioting was directed against the charges at the toll-gates on the public roads, and the rioters took as their motto the words in Gen. xiv. 60, "And they blessed Rebekah, and said unto her, Thou art our sister, be thou the mother of thousands of millions, and let thy seed possess the gate of those which hate them." Many of the rioters were disguised as women and were on horseback; each band was led by a captain called "Rebecca," his followers being known as "her daughters." They destroyed not only the gates but also the toll-houses, the work being carried out suddenly and at night, but usually without violence to the toll-keepers, who were allowed to depart with their belongings. Emboldened by success, the Rebeccaes turned their attention to other grievances. The govern-

ment despatched soldiers and police to south Wales, and the disorder was quelled. South Wales was relieved from the burden of toll-gates, while the few rioters who were captured were only lightly punished. The movement was separate from Chartistism (*q.v.*), but was supported by the same class and arose from the same economic causes.

REBELLION, the act of one who engages in armed resistance to the government to which he owes allegiance. For instance the supporters of the Old Pretender in 1715 and of the Young Pretender in 1745 were regarded and punished as rebels. In the American Civil War of secession, the Federal Government continued for two years to regard the Confederates as rebels although they had been recognized as belligerents by neutral states. And in the South African War of 1899-1902 it was held by the Supreme Court of the Cape of Good Hope that rebels who joined the Burgher forces, and thus committed high treason, remained liable to be punished for criminal offences, although the Burghers had been recognized as belligerents; *Re v. Louw* 21 C. G. H. Supreme Court Rep. 36 (1905). See LAWS OF WAR.

REBIKOV, VLADIMIR (1866-1920), Russian composer, was born at Krasnoyarsk in 1866, and studied in Moscow, Berlin and Vienna. He then went to live at Odessa, where, in 1894, his first opera, *The Thunderstorm*, was produced. Other dramatic works are *The Christmas Tree* (1903); *Narcissus*; *The Fabes of Krylov* (his best-known work); *Prince Charming*, a fairy opera; and the pantomime *Snow-White* (1909). He also wrote suites for pianoforte, including the *Melodiques*, and mimetic vocal pieces. His music makes no appeal to the popular mind, and is difficult to grasp because of its harshness and lack of form. Rebikov's literary work includes a translation of Gevaert's *Traité d'Instrumentation* (1899) and *La musique de 1900*.

REBOUX, PAUL (1877-), French author, was born in Paris on May 23, 1877. Editor of several Paris newspapers, *Le Journal*, *Paris Soir*, etc., and a well-known broadcaster; his chief novels were: *Liste ou les amours romanesques* (1902); *Le Phare* (1907) and *Trio* (1924). His historical romances, *Lady Hamilton*, *Marie Stuart*, *Meyerling* (1928), *Levi XIV* and *Le Grande Catherine*, are successful reconstructions of atmosphere and period. As an essayist, Reboux became known for a mixture of humour and sound information, for example, *Le Nouveau Savoir-vivre* (Monaco, 1930). His books on gastronomy include *Savoir-manger* and *Plais nouveaux* (1927); books on medical subjects include *Sens interdit*, *Trop d'enfants* (1931) and *Tuberculeux, on ne veut pas vous guérir* (1932). One of his most popular works is *A la manière de*, a series of satirical imitations of well-known literary works, begun in collaboration with Charles Müller in 1908 and continued by Reboux after Müller's death in action (1914); a volume was published in 1931.

REBUS, a sort of riddle consisting of the representation of some sentence or thing by means of pictures or words, or a combination of both. Rebuses first became popular in France, where they were at first called *rebûs de Picardie*, that province, according to G. Ménage (1613-92), having been the scene of their origin. Camden mentions an instance of this kind of wit in a gallant who expressed his love to a woman named Rose Hill by painting in the border of his gown a rose, a hill, an eye, a loaf, and a well;

this, in the style of the rebûs, reads "Rose Hill I love well." A specimen of a modern rebûs is given here, the solution of which is: "Be independent but not too independent" (B in D pendant, butt knot 2 in D pendant).

The name is also applied to arrangements of words in which the position of the several vocables is to be taken into account in divining the meaning. Thus "I understand you undertake to overthrow my undertaking" makes the rebûs

Stand take to taking
I you throw my.

A simple French rebûs is expressed by the two letters G, a, which may be read, *J'ai grand appétit* (G grand, a petit).

"Rebûs" (or "allusive arms"), in heraldry (*q.v.*), is a coat of arms which bears an allusion to the name of the person—as three castles for Castleton, three cups for Butler.

Ben Jonson happily ridiculed this kind of wit in his description of Abel Druggier's device in the *Alchemist*.

FROM "WORLD'S BEST WORD PUZZLES"

SPECIMEN REBÛS. SOLUTION OF WHICH IS GIVEN IN THE TEXT

RECALL, a device by which the voters may remove an official from office before the expiration of his regular term. It is based upon the principle that officials are properly mere agents of the popular will, and as such should be constantly subject to their control. Under the plan, if a specified percentage of the electorate are dissatisfied with an official's conduct and sign a petition for his removal, the officer must face a general election to determine the majority opinion.

Like the initiative and referendum the recall originated in Switzerland where it is applicable not only to individuals but to the entire legislature. In the United States where its widest use is now found, it first appeared in 1903 in the city charter of Los Angeles. It was soon adopted by many cities with the commission form of government as the most effective way to control the commissioners into whose hands such large powers were put. It was first adopted with State-wide application in Oregon in 1908, followed by California in 1911, Arizona, Idaho, Washington, Colorado and Nevada in 1912, Michigan in 1913, Louisiana, North Dakota and Kansas in 1914. Most of these were States with a large number of elective officers, who, since they were not subject to removal by the governor, were, in effect, beyond control during their term of office. In one State, Kansas, the recall extends to appointed as well as elected officials. In four of the eleven, Idaho, Louisiana, Michigan and Washington, it is not applicable to judges on the ground that the judiciary should be independent of popular passions and political issues.

Though the general principle of the recall is simple, there are many variations in its practical application, which considerably alter its effect. For instance under some plans the question of removal may be decided in one election, and the question of a successor in a subsequent election. For economy's sake the two are often combined into one election in which the official whose conduct is under question may stand as a candidate if he desires. In the latter case the question of his record is evidently complicated by the element of his comparative popularity. The vote required to remove an official may be a simple majority or a higher percentage. The percentage of signatures required to force an election ranges widely, the average being about 25%; and the methods by which it is permissible to secure signatures may vary sufficiently to affect the result. The recall has, in fact, been but seldom resorted to and then almost entirely for local officers. Only twice has it found State application, notably in North Dakota in 1921 when the governor, attorney-general and commissioner of agriculture were removed. Only a few instances of its being applied to judges are on record, all of them in minor courts. In its State-wide application it becomes too cumbersome to be frequently resorted to. Its chief value is perhaps not to be measured by the frequency with which it is applied, but by the restraining influence which its existence may exercise.

See W. E. Rappard, "Initiative, Referendum and Recall in Switzerland," *Annals of the Amer. Acad. of Political and Social Science* (Sept. 1912); W. B. Munro, *The Initiative, Referendum and Recall* (1912); J. D. Barnett, *Operation of the Initiative, Referendum and Recall in Oregon* (1915). The argument against the recall of judges is presented by W. H. Taft in his veto of the enabling act for the admission of Arizona, whose Constitution allowed such a recall (*House Ex. Doc. No. 207*, 62nd Cong. 1st Sess.).

RÉCAMIER, JEANNE FRANÇOISE JULIE ADÉLAÏDE (1777-1849), a famous Frenchwoman in the literary and political circles of the early 19th century, was born on Dec. 4, 1777, at Lyons. Her maiden name was Bernard. She was married at fifteen to the banker Jacques Récamier (d. 1830), who was more than old enough to be her father. From the early days of the consulate to almost the end of the July monarchy her salon in Paris was one of the chief resorts of literary and political society that pretended to fashion. The *habitués* of her house included many former royalists, with others, such as Bernadotte and General Moreau, more or less disaffected to the government. Through her friend Madame de Staël, Madame Récamier became acquainted with Benjamin Constant (q.v.). She was eventually exiled from Paris by Napoleon's orders. After a short stay at Lyons she proceeded to Rome, and finally to Naples, where she was on good terms with Musset and his wife, who were then intriguing with

the Bourbons. She persuaded Constant to plead the claims of Murat in a memorandum addressed to the congress of Vienna, and also induced him definitely to oppose Napoleon during the Hundred Days. Her husband had sustained heavy losses in 1805, and she visited Madame de Staël at Coppet in Switzerland. In her later days she lost most of the rest of her fortune; but she continued to receive visitors at the Abbaye-aux-Bois, the old Paris convent to which she retired in 1814. Here Chateaubriand was a constant visitor, and in a manner master of the house; but even in old age, ill-health and reduced circumstances Madame Récamier never lost her attraction. She numbered among her admirers Mathieu de Montmorency, Lucien Bonaparte, Prince Augustus of Prussia, Ballanche, J. J. Ampère and Constant, but none of them obtained over her so great an influence as did Chateaubriand, though she suffered much from his imperious temper. Her sincerest affection seems to have been for Prosper de Barante, whom she met at Coppet. She died in Paris on May 11, 1849.

There are well-known portraits of her by Louis David in the galleries of the Louvre, and by François Gérard in the possession of the préfecture of the Seine. In 1859 *Souvenirs et correspondances tirés des papiers de Madame Récamier*, was edited by Mme. Lenormant. See Mme. Lenormant's *Madame Récamier, les amis de sa jeunesse et sa correspondance intime* (1891); Mme. Mohl, *Madame Récamier*, with a sketch of the history of society in France (1829 and 1869); also Guizot in the *Revue des deux mondes* for December 1859 and February 1873; H. Noel Williams, *Madame Récamier and her Friends* (London, 1902); E. Herriot (Eng. trans. by Alys Hallard), *Madame Récamier et ses amis* (1904) (elaborate and exhaustive); L. de Launay, *Un amoureux de Madame Récamier*; *Journal de J. J. Ampère* (1927).

RECANATI, a city of the Marches, Italy, in the province of Macerata, 8 mi. direct N.N.E. of the city of that name. Pop. (1936) 5,354 (town); 16,823 (commune). It has a station on the railway 17½ mi. S. of Ancona, and distant 4½ mi. from the town, which is built on a hill, 931 ft. above the sea. It was the birthplace of the poet Leopardi (1798-1837). It possesses a Gothic cathedral, built towards the close of the 14th century and dedicated to S. Flavianus, patriarch of Constantinople. The churches of S. Maria del Mercanti and San Domenico contain pictures by Lorenzo Lotto, as also does the municipal palace, with a fine old battlemented tower, while the palace of Cardinal Venier has a fine Renaissance portico by Giuliano da Maiano. The help given the popes in their struggles with the Sforza caused the decline of the city which suffered from an earthquake in 1742 and from wars (1797-99).

RECEIPT, in law, an acknowledgment in writing that a sum of money or other valuable consideration has been received by the person signing the acknowledgment in discharge of a debt or other obligation. Such a receipt is *prima facie* evidence of payment. By the Stamp Act of 1891 a duty of 1d was imposed on every receipt or form of writing discharging a debt of £2 or upwards; the payment of the duty is denoted by affixing a stamp to the document, and the cancelling of the same by the person giving the receipt. By s. 103 if a person gives a receipt, liable to duty, not duly stamped, or refuses to give a receipt, liable to duty, duly stamped or, on payment to the amount of £2 or upwards, gives a receipt for a less sum than £2 or divides the amount paid with intent to evade the duty, he is liable to a fine of £10. A receipt not duly stamped may be stamped at the Inland Revenue Office within 14 days on payment of a fine of £5 or within one month on payment of £10. By the Finance Act of 1920 the receipt stamp was increased to 2d.

American Law.—There are no stamp duties on receipts in the United States. On the effect of a receipt in full, given against payment of less than the amount due, see *Discharge*. On receipts for goods given by transportation or storage agencies see *Bill of Lading, Warehouse Receipt*. The commercial practice of a debtor requiring a receipt on paying a debt has, curiously, no warrant in law except in particular cases: a debtor paying a negotiable instrument (see *BILL OF EXCHANGE*) is entitled to have it surrendered to him, which serves as a receipt; and a mortgagor paying off a mortgage is entitled to receive from the mortgagee a "satisfaction piece" which serves as evidence that the obligation and the mortgage are discharged. In other cases.

in general, the debtor's assurance of procuring a receipt rests partly on business custom, partly on the creditor's practical desire to collect his debt and on his willingness to accept payment by check, which will then serve as a receipt.

RECEIVER, in English and American law, a person appointed by a court to administer property for its protection, to receive rent or other income and to pay authorized outgoings. Receivers may be either appointed *pendente lite* or by way of equitable execution, e.g., for the purpose of enabling a judgment creditor to obtain payment of his debt, when the position of the real estate is such that ordinary execution will not reach it. Formerly receivers were appointed only by the court of chancery, but by the Judicature Act of 1873 it is now within the power of all divisions of the High Court to appoint receivers. Their powers and their duties are set forth by Kerr, *On Receivers* (5th ed., 1905), who classifies the cases in which they may be appointed under the following heads: (a) infants; (b) executors and trustees; (c) pending litigation as to probate; (d) mortgagor and mortgagee; (e) debtor and creditor; (f) public companies; (g) vendor and purchaser; (h) covenant and covenantee; (i) tenant for life and remainderman; (j) partners; (k) lunacy; (l) tenants in common; (m) possession under legal title, and (n) other cases. The appointment of receivers is entirely within the discretion of the courts. In bankruptcy practice a receiver, termed official receiver, is an officer of the court who in this capacity takes possession of all a debtor's assets. In the United States the appointment of receivers lies within the jurisdiction of courts that are invested with equity powers and in exercise of their equity jurisdiction. Under statutes in many States the power to appoint receivers has been extended to actions at law in various types of cases. (See *BANKRUPTCY*.)

RECEIVING: see *LARCENY*.

RECEIVING SET, the equipment that reproduces speech, music, visible messages or signals from radio waves. (See *RADIO*; *RADIO RECEIVER*; *TELEVISION*.)

RECHABITES or **SONS OF RECHAB**, a sort of religious order among the Israelites, analogous to the *NAZARITES* (q.v.), with whom they shared the rule of abstinence from wine. They eschewed settled life, and lived in tents, refusing to sow grain or plant vineyards. They represented a protest against the contemporary civilization and a reaction towards simplicity of life. Their "father," or founder, was that Jehonadab (or Jonadab) son of Rechab, who encouraged Jehu to abolish the Tyrian Baal-worship (2 Kings x.). The "house of Rechab" fled for protection into Jerusalem at the approach of Nebuchadnezzar (Jer. xxxv.), and Jeremiah promised them, as a reward of their adherence to the ordinance of Jehonadab, that they should never lack a man to represent them (as a priest) before Yahweh. Later Jewish tradition states that the Rechabites intermarried with the Levites.

RECHBERG-ROTHENLÖWEN, JOHANN BERNHARD, COUNT (1806-1899), Austrian statesman, was the second son of the Bavarian statesman Count Aloys von Rechberg-Rothentöwen (1766-1849). Johann Bernhard was destined for the Bavarian public service, and he was educated at the universities of Strasbourg and Munich, but incurred the displeasure of King Louis I. by the part he played as second in a duel, and in 1828 transferred to the Austrian diplomatic service. After being attached to the embassies in Berlin, London and Brussels, he was appointed envoy at Stockholm (1841) and at Rio de Janeiro (1843). Returning to Europe in 1847, on the outbreak of the revolution of 1848 in Vienna he accompanied and assisted Prince Metternich in his flight to England. In July 1848 he was appointed Austrian plenipotentiary in the German federal diet at Frankfurt, and in 1851 became Austrian *interruncius* at Constantinople, and in 1853 Radetzky's civilian colleague in the government of Lombardo-Venetia. In 1855 he returned to Frankfurt as Austrian representative and president of the federal diet. Here his constant disputes with Bismarck, at that time Prussian envoy at the diet, were much sharpened by Rechberg's choleric temper, and on one occasion nearly led to a duel. Bismarck, however, always expressed a high appreciation of his character and abilities. In May 1859, on the eve of the war with Italy, he was appointed

Austrian minister of foreign affairs and minister president, surrendering the latter post to the archduke Rainer next year.

The five years during which Rechberg held the portfolio of foreign affairs covered the war with Italy and France, the insurrection in Poland, the attempted reform of the German Confederation through the Frankfurt *Fürstentag*, and the Austro-Prussian war with Denmark. Their story is told elsewhere. (See *AUSTRIA, EMPIRE OF*; *EUROPE*.) In the German question Rechberg's policy was one of compromise, and he generally advocated peaceful arrangement between Prussia and Austria as the indispensable preliminary to a reform of the Confederation. In the Schleswig-Holstein question he was, however, consistently outwitted by Bismarck, and on Oct. 27, 1864, Rechberg resigned. He received the Golden Fleece from the emperor as a sign of special favour. He had been made an hereditary member of the Upper House of the *Reichsrat* in 1861, and as late as 1879 continued occasionally to take part in debates. He died at his Kettenhof near Vienna on Feb. 26, 1899.

See the biography by Franz Ilwof in *Allgemeine Deutsche Biographie*, B. 53. *Nachträge* (Leipzig, 1907).

RECIDIVISM, a disposition or tendency to relapse into crime. While such a disposition may not be a matter of habit but the consequence of mental disorder or congenital defect, the term recidivist is, in criminology, usually employed interchangeably with "habitual offender" (q.v.).

RECIFE or **PERNAMBUCO**, a city and seaport of Brazil, capital of the state of Pernambuco, in 8° 3' S. and 34° 51' W., near the easternmost point of South America. The *município* of Recife, which is divided into two *distritos* and has an area of 60 sq.mi., had a population of 334,468 in 1950. The city had a population of 522,466.

At the mouth of the Capibaribe river, the city is comprised of four separate parts (Recife, Santo Antonio, São José and Boa Vista) which are integrated by numerous bridges.

The district of Recife occupies the southern end of the Olinda peninsula and is the principal commercial centre of the city. In addition to warehouses and terminal facilities, there are the customhouse, observatory, naval arsenal, government offices, several of the consulates and many of the more important banks, business houses and retail stores.

Santo Antonio, known as Mauritá or Mauritzstad during the period of Dutch occupation, is on an island of the same name. Among the important institutions and public buildings in this part of the city are the government palace, the state treasury, the court-house, the state museum, public library, several fine churches, including the city's famous church of São Francisco de Assis, the Santa Isabel theatre and many historic landmarks.

São José embraces a large district on the mainland and is chiefly residential in character. The Dutch fort of Cinco Pontas is in this section of the city, as is Restoration square, which commemorates the end of Dutch domination.

Boa Vista, also on the mainland, is both a commercial and residential district and contains many of the educational institutions of Recife, including a normal school and schools of law, medicine, engineering, commerce and fine arts.

Because of the waterways which separate the component parts of the city, Recife is often referred to as the "Venice of America."

Its position near the equator and low elevation combine to produce a hot climate which, however, is mitigated somewhat by the southeast trade winds. July, the coolest month, has a mean temperature of 77°, whereas from December through March it is 82°. The total annual rainfall, based upon a 47-year record, is 65 in., more than 80% of which falls from March through August.

The port of Recife is one of the most important of Brazil because of its proximity to Europe and its convenience for vessels passing around the east shoulder of the continent. Its harbour consists of a narrow body of water, about 2 mi. in length, which is sheltered on the east by a reef and breakwater. The latter extends about 3,600 ft. in a north and northeasterly direction from the reef—an ancient beach of firmly consolidated materials. A

second breakwater (Olinda Mole), about 2,500 ft. in length, runs in a southeasterly direction from the mainland and forms the other wing of the entrance channel. The distance between the heads of these two breakwaters is about 900 ft. The northern part of the harbour is approximately 1,600 ft. in width and has been dredged to a low water depth of 32 ft. The southern part is considerably smaller and has been dredged to a depth of but 25 ft. The quay is along the eastern margin of the peninsular district of Recife. The port is equipped with a modern coaling plant and grain conveyor, each having a capacity of 300 tons per hour, a sugar conveyor having a capacity of 1,600 bags per hour and more than 50 electric and steam cranes, the largest of which (floating) has a 30-ton capacity. Three sets of tracks, which connect with the Great Western of Brazil railway, serve the wharf and warehouses. There are 15 concrete warehouses having a total floor space of approximately 400,000 sq. ft., a cold storage warehouse, a warehouse for commodities which create a public hazard and 15 tanks for petroleum products and alcohol. The terminal facilities are operated by a state *directoria* under the authority of the federal government.

The principal imports of Recife are coal, petroleum and wheat; total imports in 1949 amounted to 571,174 short tons. Exports consist largely of sugar (the state of Pernambuco being the second largest producer in Brazil), cotton and other agricultural products. The total outbound traffic in 1949 amounted to 77,542 short tons.

More than 1,600 mi. of railways serve the states of Pernambuco, Alagoas, Paraíba and Rio Grande do Norte, having outlet through Recife, and a well-developed system of surfaced roads provides additional transportation facilities.

Recife, served by Panair do Brasil, a subsidiary of Pan American World Airways, as well as by several other national and European air lines, has national and international cable connections and radio, telegraph and telephone communications. Recife was settled about 1535, when Duarte Coelho Pereira landed there to take possession of the county granted him by the Portuguese crown. The site of Coelho's capital was Olinda, but Recife remained its port and did not become an independent *vila* (town) until 1710.

Down to the close of the 18th century, when Rio de Janeiro became important, Recife was the second city of Brazil and for a time its most important port. It was captured and plundered in 1695 by the English privateer James Lancaster. It was also captured by the Dutch in 1656 and remained in their possession till 1654, during which time the island of Santo Antonio was occupied and the town greatly improved. At the end of the Dutch war the capital was removed from Olinda to Recife, where it has since remained.

RECIPROCATING ENGINE; see STEAM ENGINE.

RECIPROCITY, the condition or state of being reciprocal, i.e., where there is give and take, mutual influence, or correspondence between two parties, persons or things (Lat. *reciprocus*, returning back the same way, alternating, probably from *re* back and *pro* forward). In a more particular sense, reciprocity refers to the commercial policy under which a country grants special tariff advantages to imports of another country in return for special tariff advantages granted to it by the other country. In American usage the terms "reciprocity" and "reciprocity agreements" have acquired a highly specialized meaning as a result of the tariff policy formerly pursued by the United States, particularly under the tariff acts of 1890 and 1897, in the negotiation of tariff agreements with other countries. In this specialized sense, a reciprocity agreement is one in which the contracting states grant to each other particular tariff concessions, in return for particular tariff concessions, without the intention or expectation that these concessions will be generalized, i.e. extended to third countries. Reciprocity agreements are to be distinguished from reciprocal trade agreements concluded by the United States since 1934, in which the tariff reductions made by the United States (except in the Cuban agreement) have been generalized to all countries except those found to be discriminating against American trade.

(H. F. G.)

RECKLINGHAUSEN, a town in the province of North

Rhine-Westphalia, Germany, 22 mi. N.W. of Dortmund. Pop. (1950) 104,791. The county of Recklinghausen belonged to the archbishopric of Cologne until 1803, when it passed to the duke of Arenberg. It was known as the West Recklinghausen. After 1815 the duke of Arenberg held it as a fief under Prussian sovereignty. In the neighbourhood of Recklinghausen are extensive coal-mines, iron and tin foundries and brick works, and the industries embrace the manufacture of linen, beer, spirits, cement, soap and ammonia.

RECLAMATION OF LAND; see LAND RECLAMATION.

RECLUS, JEAN JACQUES ELISÉE (1830-1905), French geographer, was born at Sainte-Foy la Grande (Gironde), on March 15, 1830, the second son of a Protestant pastor. He was educated at the Protestant college of Montauban, and studied geography under Karl Ritter at the University of Berlin. Leaving France in December 1851, he spent six years (1852-57) visiting the British Isles, the United States, Central America, and Colombia. During the siege of Paris, Reclus shared in Nadar's aerostatic operations. He was taken prisoner on April 5, 1871, while serving in the National Guard, now in open revolt, and on Nov. 16 sentenced to transportation for life; but the sentence was commuted in Jan. 1872 to perpetual banishment. After a short visit to Italy, he settled at Claren, in Switzerland, where he resumed his literary labours, and, after producing the *Histoire d'une montagne* (a companion to *Histoire d'un ruisseau*), wrote nearly the whole of his great work, *La Nouvelle Géographie universelle, la terre et les hommes*, 10 vols. (1875-94). This is a stupendous compilation, profusely illustrated with maps, plans and engravings, and was crowned with the gold medal of the Paris Geographical Society in 1892. An English edition appeared simultaneously, also in 10 vols., the first four by E. G. Ravenstein, the rest by A. H. Keane. Extreme accuracy and brilliant exposition form the leading characteristics of all Reclus's writings, which thus possess permanent literary and scientific value. In 1882 Reclus initiated the "Anti-Marriage Movement," in accordance with which he allowed his two daughters to marry without any civil or religious sanction. This resulted in government prosecutions, instituted in the High Court of Lyons, against the anarchists, members of the International Association, of which Reclus and Prince Kropotkin were designated as the two chief organizers. The prince was arrested and condemned to five years' imprisonment, but Reclus, being resident in Switzerland, escaped. In 1892 he became professor of comparative geography in the University of Brussels. Reclus died on July 4, 1905.

His works are: *Histoire d'un ruisseau* (1869); *La Terre: description des phénomènes de la vie du globe* (8 vols., 1867-1868); *Histoire d'une montagne* (1880); *La Nouvelle Géographie universelle, la terre et les hommes* (10 vols., 1875-1894); *L'Homme et la terre* (1905); and many contributions to scientific journals.

RECOGNIZANCE, a term of common law usually employed to describe an obligation of record, entered into before some court or magistrate duly authorized, whereby the party bound acknowledges that he owes a personal debt to the Crown, with a defeasance, i.e., subject to a condition that the obligation to pay shall be avoided if he shall do some particular act—as if he shall appear at the assizes, keep the peace, or the like. Recognizances are now used almost solely with reference to criminal proceedings. The security given by a receiver appointed by the High Court is still in the form of a recognizance acknowledging a debt to named officers of the court, and securing it on the real and personal estate of the receiver.

There is a general jurisdiction on conviction of misdemeanour both at common law and by statute to put the offender under recognizances to keep the peace and (or) be of good behaviour in addition to or in substitution for other punishment. On refusal to enter into recognizances as above, the court may order imprisonment for the refusal, limited in cases within the Acts to 12 months, and in cases within the Act of 1879 to six months.

The recognizances above described may be described as a form of punishment or a judicial security for good conduct. Recognizances are, however, most used with reference to proceedings before conviction and judgment. In preliminary enquiries into indictable offences the enquiring justices take recognizances to

ensure the attendance of the accused if liberated during any adjournment, and on commitment for trial take the recognizances of the accused (if allowed bail) to attend the court of trial and take his trial, and of the prosecutor and the witnesses for the prosecution or defence to attend and prosecute or give evidence. Recognizances taken are returnable under penalty to the court of trial, which orders their estreat (i.e.) if the conditions are breached. Similar powers as to the recognizances of persons prosecuted summarily were given by the Summary Jurisdiction acts, 1848 and 1879, amended by the Criminal Justice act, 1925.

By the Land Charges act, 1925, a recognizance, whether obtained or entered into on behalf of the crown or otherwise, did not operate as a charge on land or on any interest on land or on the unpaid purchase money for any land, unless a writ or order for the purpose of enforcing it was registered in the office of the land registry. This enactment was clearly applicable to receivers' recognizances; and on purchases of land search was made for registered recognizances and an official certificate could be obtained affirming or negating the existence of a registered entry.

In the U.S.A., the states allow by either common law or statutes recognizances in much the same way as in England.

RECONNAISSANCE, a military term for reconnoitring or examination of an enemy's position or movements. A topographical reconnaissance is a survey of a tract of country or route, by officers with small patrols, escorts or assistants. Strategic reconnaissance was formerly carried out by cavalry formations or squadrons, but it has now been taken over almost entirely by aircraft. Tactical reconnaissance falls to the lot of troops of all arms, whether in contact with the enemy or for self-protection. In this task lies now the main use of cavalry, infantry divisions being usually endowed with either a regiment or a squadron. A reconnaissance by a large force of all arms with the idea of provoking an enemy into showing his hand, if necessary by fighting, is called a reconnaissance in force.

RECONSTRUCTION FINANCE CORPORATION, in the U.S., was established by act of congress, Jan. 22, 1932, to "provide emergency financing facilities for financial institutions, to aid in financing agriculture, commerce, and industry."

Management and Organization.—In 1931 the former board of directors was abolished. Management and direction of the RFC was vested in an administrator and deputy administrator appointed by the president with the advice and consent of the senate. A loan policy board was established with the administrator as chairman.

Functions.—The RFC was authorized to make loans to business enterprises (including railroads and air carriers); to make loans to financial institutions; to subscribe for and make loans upon the nonassessable preferred stock of insurance companies and to purchase the legally issued capital notes and debentures thereof; to purchase the securities of and make loans to state, municipalities and other public agencies; and to make loans because of floods or other catastrophes.

Under the RFC act, as amended, the Defense Production act of 1950 and executive orders and regulations, the corporation also could make loans (including bank participations) to business enterprises for the purpose of financing defense or essential civilian requirements. In addition, the corporation was authorized to purchase securities or to make loans (including participations therein or guarantees thereof) for the purpose of aiding in financing projects for civil defense purposes.

Other functions related to the production of strategic and critical materials—synthetic rubber, tin and abaca (Manila hemp)—and the liquidation of certain defense plants and facilities.

Recovery Period.—During the 1930s, when the United States experienced the worst depression in its history, the need was recognized of giving special assistance to owners of real estate and holders of real estate mortgages. The RFC, while not dealing directly with the individual borrowers under federally insured mortgages, nevertheless assisted them through the creation of a market for such mortgages. Its activities along this line were directed toward creating confidence in real estate and thereby encouraging home building.

The RFC Mortgage company was formed at a time when practically no mortgage money was available to deserving borrowers to protect their business properties from foreclosure. Congress authorized the corporation in Jan. 1935 to invest in the capital stock of mortgage companies up to \$500,000,000 when any such investment was approved by the president, following which the corporation, with the approval of the president, subscribed for the capital stock of the RFC Mortgage company March 14, 1935, in the amount of \$10,000,000, later increased to \$25,000,000. The stock was all owned by the RFC.

The Federal National Mortgage association was organized by the RFC in 1938 under the authority of the National Housing act. Owned and operated by the RFC, it was established to deal exclusively with mortgages insured by the Federal Housing administration.

World War II.—As part of the national defense program, the RFC was empowered by congress to lend its full credit facilities to producers of war goods. Affected were not only the large suppliers of products needed by the military, as well as the civilian, front of the country but also tens of thousands of small suppliers. In addition the RFC was authorized to create new production facilities, to install special types of machinery in privately owned plants and to create stockpiles of critical and strategic materials for use in war production.

To enable the RFC to perform these functions, the president, on June 25, 1940, signed an act of congress authorizing the corporation to act through subsidiary corporations to be created by it, for purposes of national defense; to build and operate plants and facilities for the manufacture of matériel; to procure supplies and equipment, and to buy materials declared by the president to be strategic and critical. Various subsidiaries were created, such as the Defense Plant corporation, Rubber Reserve company, Metals Reserve company and Defense Supplies corporation. After the war, their functions, powers, duties and authority were transferred to the RFC.

The War Damage corporation was organized by the RFC on Dec. 13, 1941, to provide governmental insurance against loss of or damage to property as a result of enemy attack. War risk insurance on other than marine risks was practically unobtainable at the outbreak of the war.

Post-World War II.—On June 5, 1946, a small business division was organized by the RFC, the function of which was to deal with special small business problems; to develop and co-ordinate advisory services for loan applicants and borrowers; to co-operate with the Veterans administration and the department of commerce in matters pertaining to small business and to assist small business in buying surplus property. Until March 1946, when the War Assets administration took over, the RFC was responsible for the disposal of many items of surplus property. From May 1, 1944, until the close of the program, surplus aircraft and capital and producers' goods costing \$12,912,000,000 was turned over to the RFC for disposal.

Total loans and investments outstanding on June 30, 1953 (excluding loans under the Defense Production act) amounted to \$652,800,000. On the same date 195 loans were approved under the Defense Production act with outstanding balances totalling \$123,200,000. Starting in the final quarter of 1953, the RFC began an organized liquidation program to transfer loans and assets of the corporation into private banking channels. In July 1953 the president had signed a bill abolishing the Reconstruction Finance corporation and establishing the Small Business administration.

(C. B. H.; K. R. Cr.; X.)

RECORDER. The principal legal officer of an English city or borough having a court of quarter sessions. He must be a barrister of five years' standing, appointed by the crown. The recorder holds office in every quarter of a year, or oftener if he thinks fit, a court of quarter sessions in and for the borough. He is sole judge of the court, "having cognizance of all crimes, offences, and matters cognizable by courts of quarter sessions for counties in England," except that he may not allow or levy any borough rate, or grant licences (s. 165). He is not eligible to serve in parliament for the borough, or to be an alderman or

councillor, or stipendiary magistrate for the borough, though he is eligible to serve in parliament except for the borough. He may be appointed recorder for two or more boroughs conjointly. Appeals from the city and borough justices, and under the Rating and Valuation Act, 1925, are to the recorder as sole judge.

The recorder of London is judge of the lord mayor's court, and one of the commissioners of the central criminal court. (See QUARTER SESSIONS, COURT OF.)

In the United States, most of the states have county recorders elected by the voters of the county. In some of the states, the duties of the recorder fall upon the clerk of one of the courts. In all of the states provision is made by constitution or statutes for some official to record deeds and other legal instruments. In New York the recorder is one of the criminal court judges.

RECORDER, **PIPPLE FLUTE** or **ENGLISH FLUTE**, a mediaeval flute, blown by means of a whistle mouthpiece and held vertically in front of the performer like a clarinet. It consisted of a wooden tube, which was at first cylindrical or nearly so, but became, as the instrument developed and improved, an inverted cone.

Being very easy to play, the recorder enjoyed great popularity in all countries after the middle of the 18th century until the greater possibilities of the transverse flute turned the tide against it. After 1800 a smaller variety, called the flageolet, played a certain role as an amateur instrument in England (where even double and triple flageolets were built). In the 20th century an increased interest in ancient music brought forth a renaissance of the recorder, produced in various sizes.

RECORDING, PHONOGRAPHIC: see **GRAMOPHONE**.

RECTIFIER, as used in radio, consists of a device for the direct conversion of an alternating-current wave into a unidirectional wave.

RECTOR, a title given to the bearers of certain ecclesiastical and academic offices. In the Roman empire, after Constantine, the title rector was borne by governors of provinces subordinate to the prefects or exarchs. In the middle ages it was given to certain secular officials (e.g., the podestats of some Italian towns), but more especially to the heads of the universities, the representatives and rulers of the *universitas magistrorum et scholarum*, elected usually for a very short time. After the humanistic movement of the Renaissance the style rector was also given to the chief masters of schools containing several classes, and in some parts of Germany (e.g., Saxony, Württemberg) it is still thus used instead of the more modern title of director. Rector is also still the title of the heads of the Scottish universities (Lord Rector) and of the German universities (*Rector Magnificus*). Rector is the title of the heads of Exeter and Lincoln Colleges, Oxford. The heads of all Jesuit colleges are also known as rectors.

As an ecclesiastical title rector was once loosely used for rulers of the Church generally, whether bishops, abbots or parish priests, but it is now confined, as in Poland and Spain, to a priest with a cure of souls, in England to the incumbent of a parish where the tithes are not inappropriate and in the U.S. to the Protestant Episcopal clergyman in charge of a parish.

RECUSANT (Lat. *recusare*, to refuse), the name given in the 16th and 17th centuries to persons, particularly to adherents of the Roman faith, who persisted in refusing to attend the services of the English Church, and became thereby liable to prosecution and penalties.

RED BANK, a borough of Monmouth county, New Jersey, U.S., on an estuary called the Shrewsbury river, 6 mi. from the Atlantic ocean and 25 mi. S. of New York city. Pop. was 12,710 in 1950; 10,974 in 1940 by the federal census. It is served by the Central Railroad Company of New Jersey and the Pennsylvania railroad and by motorbus lines. It is a residential suburb, a summer resort and the trade centre of a rich farming region; and has fish industries, canneries, nurseries and various manufacturing plants. The name Red Bank was applied to this locality as early as 1734, and by 1780 there were several buildings within the limits of the present borough.

REDBREAST or **ROBIN**, a favourite among English birds because of its pleasing colour, its sagacity and fearlessness of man,

and its song. In July and August the hedgerows of the southern counties of England are beset with redbreasts, each bird keeping its own distance from the next, on their way to cross the English channel. A number of these redbreasts, as well as native birds, remain throughout the winter. On the continent the migration is still more marked, and the redbreast is then caught in numbers for the table. The first sharp frost makes them change their habitation, and a heavy fall of snow drives them toward the homesteads for food. The nest is usually built of moss and dead leaves, with a lining of hair. In this are laid from five to seven white eggs, sprinkled or blotched with light red. Two or three broods are raised. On the continent, the redbreast is, on the whole, a forest bird, not frequenting houses like the British form.

Although the female has a breast only a little duller than the male, the latter alone displays the red in courtship. After the young are reared, fights take place between them and the adults for the possession of the territory for the winter. The robin, like most insectivorous birds, throws up the indigestible parts of its food in the form of pellets.

Besides the British islands, the redbreast (*Erithacus rubecula*) is generally dispersed over Europe, and is in winter found in the oases of the Sahara. In northern Iran it is replaced by a nearly allied form, *E. hyrcanus*, distinguishable by its more ruddy hues, while in northern China and Japan another species, *E. akahige*, is found, of which the sexes differ in plumage—the cock having a blackish band below his red breast and greyish-black flanks, while the hen resembles the British species—but both sexes have the tail chestnut red. The genus *Erithacus* belongs to the family *Turdidae* or thrushes (q.v.).

English colonists in distant lands have applied the common nickname of the redbreast to other birds. The ordinary robin of North America is a thrush (see **ROBIN**), and one of the bluebirds (q.v.) of the same continent is in ordinary speech the blue robin; the Australian and Pacific robins have not all even the red breast; the Cape robin is *Cossophya caffra*, the Indian robin *Tamnomia* and the New Zealand robin *Miro*.

RED-BUD: see **JUDASTREE**.

REDCAR, a municipal borough in the north riding of Yorkshire, England, 8 mi. N.E. of Middlesbrough on the North-Eastern Region Railway route. Pop. (1938) 23,390. Area, 11 sq.mi.

Redcar is situated on the northeast coast of Yorkshire, midway along the continuous stretch of sand beaches between the Tees estuary and Saltburn. It thus serves as a residential town and a holiday resort for the dense industrial population employed in Middlesbrough. The population grew so rapidly with the rise of Middlesbrough that the longtime separate villages of Redcar and Coatham coalesced into one compact town.

Redcar was incorporated in Nov. 1922 and is the only borough in the Cleveland parliamentary division. Building is extensive to accommodate the needs of the growing population.

RED CROSS, the national and international agency whose primary purpose is to care for the sick, the wounded and prisoners in time of war. The Red Cross movement, especially after 1919, showed a world-wide tendency to regard the prevention and alleviation of all human suffering as within the purview of Red Cross activity.

Origins of the Movement.—The fundamental idea associated with the Red Cross resulted from the publication by Henri Dunant, at Geneva, Switzerland, in 1862, of a booklet entitled *Un Souvenir de Solferino*. Dunant had witnessed appalling scenes of bloodshed during the war of 1859 in Italy and his booklet gave a shocking account of the distress of the wounded left to die on the battlefield for lack of medical assistance. He urged the necessity of constituting permanent societies for the aid of the wounded, with the purpose of forming detachments of volunteer helpers, and expressed the hope that "the leaders of the military art of different nationalities agree upon some sacred international principle; sanctioned by convention, which, once signed and ratified, would serve as the basis for the creation of societies for the aid of the wounded in the different European countries."

Dunant's appeal quickly found its echo. The Société Genevoise d'Utilité Publique had as president Gustave Moynier, who was

impressed by the importance of the suggestions set forth in Dunant's booklet. At his request Dunant attended a meeting of this society and explained his ideas. The society thereupon named a commission to study ways to improve the condition of the wounded in war. The members of this commission, destined to become the Comité International de la Croix-Rouge, were: Gen. Guillaume Dufour, commander in chief of the Swiss army, Gustave Moynier, Henri Dunant, Louis Appia and Theodore Maunoir.

After drafting an agreement providing for the formation of national committees to assist army medical services by creating voluntary aid corps, they held an international meeting at Geneva from Oct. 26 to 29, 1863. Thirty-six experts and government delegates met at the Palais de l'Athénée, and there enunciated the fundamental principles of the Red Cross.

The International committee was urged to continue the mission it had assumed as guardian of the principles laid down in the convention, and to foster the formation of national societies in all countries to develop the Red Cross movement and organize aid for wounded soldiers and other victims of war.

The next step was to secure international legal status for the movement thus set on foot, ensuring the wounded themselves, the personnel engaged in their care and the medical supplies set aside for their use against attack, the whole being protected by a single recognized emblem. The difficulties were enormous, but they were successfully overcome through the prestige of General Dufour, the activity of Henri Dunant (who personally approached the authorities in a number of countries) and the organizational work of Gustave Moynier. Napoleon III brought his influence to bear in favour of the work, and the International committee induced the Swiss federal council to convoke in Geneva on Aug. 8, 1864, a diplomatic conference at which 26 governments were represented. The outcome of this conference was the Geneva convention, which laid down certain principles: the wounded were to be respected; military hospitals to be regarded as neutral; the personnel and material of the medical services were accorded protection; and the symbol of this protection was to be a white flag bearing a red cross (the emblem of the Red Cross throughout the world). The Geneva convention, as revised July 6, 1906, was extended to sea warfare at The Hague in 1907, to the treatment of prisoners of war in 1929, and was further extended and modernized at Geneva in 1949. (J. T. NN.)

INTERNATIONAL COMMITTEE OF THE RED CROSS

The objects of the International Committee of the Red Cross (Comité International de la Croix-Rouge) are to maintain the essential principles of the Red Cross, to recognize new national Red Cross societies after verification of the basis upon which they are founded, to work for the observance and development of international humanitarian conventions (especially the Geneva conventions) and to act as benevolent intermediary between governments and national Red Cross societies in time of international or civil war; in addition, in wartime, to establish information agencies concerning prisoners of war, to visit the prisoners in their camps and to improve their material and moral situation by using all available influence; and finally, both in wartime and in peacetime, to act as benevolent intermediary between governments, Red Cross societies and other relief organizations for the purpose of carrying out itself, or enabling others to carry out, the humanitarian task of relieving suffering caused by war and calamities.

The International committee's headquarters are at Geneva, where it was founded in 1863. Recruited by co-optation, the committee possesses juridical personality. The term "international" describes the nature of the committee's work, which is international in scope, while its composition is wholly Swiss (25 members elected by co-optation) to ensure neutrality of its activities in all countries. The committee's activities are governed by the principles upon which the Red Cross rests: absolute impartiality and independence, especially in political and religious matters, and equality as between all members of the great Red Cross family. A link between the committee and national societies is provided by the *Bulletin international de la Croix-Rouge* (from 1864) and the *Revue internationale de la Croix-Rouge* (from 1919).

The committee also publishes books, pamphlets, etc., dealing with Red Cross principles and activities.

In 1928, the 13th International Red Cross conference at The Hague established the statutes of the International Red Cross, which comprises the national societies, the International committee and the League of Red Cross Societies. These three elements are the basis of the universal Red Cross movement, whose assembly, the International conference, normally takes place every four years.

The committee was entrusted by the International Red Cross conference with the periodical distribution of Florence Nightingale medals, awarded to the most deserving nurses of all countries. In 1917 and again in 1944 it was awarded the Nobel peace prize.

World War I.—In successive European conflicts from 1864 the committee established agencies for information and the relief of wounded and sick combatants. Relief for prisoners of war was an accessory concern of the Red Cross in 1870 and was not recognized officially before 1912 (Balkan War). At the outbreak of World War I the committee opened the International Prisoners of War agency in Geneva with a staff, mainly voluntary, of about 1,200 persons. Forty-one delegates visited 524 internment camps, and facilities were obtained for the evacuation of civilians from occupied regions (northern France) and the repatriation or accommodation in neutral countries of sick and wounded combatants and medical personnel. The work relative to the eastern front was delegated to the Danish Red Cross, which set up an extensive information bureau for this purpose in Copenhagen.

The work of the committee and its agency in this war showed the insufficiency of treaty stipulations governing the situation of prisoners of war (ruled only by the regulations annexed to the fourth Hague convention of 1907), and contributed materially to the drafting and adoption in 1929 of the Geneva Prisoners of War convention.

Activities Between World Wars I and II.—After the war, the International committee organized the repatriation of 450,000 prisoners of war of all nationalities from Russia and from central Europe; it also effected the exchange of hostages in Upper Silesia, the return of Bulgarians interned in Greece and the exchange of prisoners between Greece and Turkey. In medical relief and reconstruction work in war-stricken countries, the committee co-operated actively with numerous Red Cross societies and other organizations.

After the treaty of Versailles, world opinion was largely dominated by the belief that the covenant of the League of Nations had banished war. The committee's specific function being inseparable from the circumstance of war, certain circles at that time held its continued existence to be at best an anachronism, and at worst a connivance at future attempts to revert to arms. From 1919 to 1929 the committee went through a critical period, withstanding widespread opposition in its refusal to yield to premature and dangerous optimism, and its insistence that so long as even a remote possibility of war remained the Red Cross was pledged to preparedness for its fundamental wartime tasks.

World War I had revealed grave deficiencies in international law, notably with regard to the treatment of prisoners of war and civilian internees, and had shown the urgent need of bringing civilians under protection. Ten years' intensive preparation led in 1929 to the revised convention for the relief of sick and wounded combatants, and the adoption of a new convention relative to the treatment of prisoners of war. At the 15th International Red Cross conference in Tokyo, Jap. (1934), a draft convention for the protection of civilians was approved, but the diplomatic conference convened for 1940, at which these proposals would have become law, was prevented by the outbreak of World War II. The Tokyo draft, however, served the committee to obtain the granting by all belligerents in World War II of prisoner-of-war status to interned enemy aliens. The 16th International Red Cross conference (London, 1938) put forward proposals on the following subjects: revision of the Geneva convention of 1929 (prisoners of war), and of the Hague convention of 1907 for the adaptation of the Geneva convention to war at sea; draft conventions: (1) for adaptation of the same to aerial warfare; (2) for

medical and security zones in wartime; and (3) concerning the condition and protection of civilians of enemy nationality in enemy or enemy-occupied territory.

Both the Gran Chaco War in the early 1930s and the Spanish Civil War (1936-39) called into action one of the International committee's most important humanitarian functions—to persuade belligerents not legally bound by conventions to accept their terms nevertheless. Combatants and civilians were thus spared much suffering as a result of the committee's intervention, through its delegates, in the above conflicts. The committee's services were also called upon during the wars in Ethiopia and China.

Numerous legal problems arising out of Red Cross functions and activities permanently occupy the committee in peacetime. Its work in connection with the subjects of the draft conventions and other measures for mitigating the destruction of life and property in wartime proved of great practical and moral value during World War II, either in obtaining good-will concessions, or as the basis of appeals to belligerent powers.

World War II.—In pursuance of article 79 of the Prisoner of War convention the committee opened the Central Prisoner of War agency in Geneva in Sept. 1939. As from 1940, the agency was considerably extended; all the other activities of the committee increased steadily and several new departments were added, especially in the field of relief supplies and transport by sea and land. The committee's staff, which in Sept. 1939 numbered 20, totalled 3,921 in June 1945, half of them voluntary workers. The committee's delegations in all countries numbered 81, comprising 179 delegates who paid more than 11,000 visits to prisoner-of-war camps.

At the end of 1946, the card index of the agency relating to prisoners of war and internees included about 39,000,000 cards. Incoming mail items had totalled 58,701,000, outgoing 60,393,000; telegrams received were 346,696, dispatched 218,582. Civilian messages for correspondence between free civilians in countries at war reached nearly 24,000,000. Close to 1,500,000 printed volumes for recreation or study, contributed by various relief organizations, had been forwarded to the camps. Relief supplies for prisoners and internees reached a total weight of 445,702 tons, valued at 3,400,000,000 Fr. (Swiss). Expenditure for the period 1940-46 amounted to 54,875,509 Fr. and contributions totalled 51,797,768 Fr., half of which were subscribed by Switzerland.

Relief for civilian war victims—particularly women and children—was the purpose of the Joint Relief commission of the International Red Cross, created in July 1941 (at the committee's suggestion) by the International committee and the League of Red Cross Societies. Foodstuffs, clothing and pharmaceutical supplies bought and dispatched by the Joint commission were distributed in the war-stricken countries by national Red Cross societies and other welfare organizations in the presence, whenever possible, of a delegate of the committee. From 1941 to 1946, the Joint Relief commission purchased and forwarded 83,000 tons of supplies valued at 340,000,000 Fr. The chief countries benefited were Belgium, France, Greece, Yugoslavia, the Netherlands, Norway and Poland. The commission's most notable relief schemes were for Belgian children in 1941 and for the famine-stricken Greek population during the winter of 1941-42. This last project was carried out conjointly with the Swedish government and the Swiss Red Cross society, and with the assistance of the Turkish Red Crescent. Organized by delegates at Athens, it saved the lives of 5% to 10% of the population of that city, and enabled 40% of the population to sustain life.

The strictness of the blockade and counterblockade, the scarcity of neutral shipping available and the vast extension of the relief scheme led to the creation of a Red Cross maritime transport system. The Foundation of the Organization of Red Cross Transports, set up by the committee in April 1942, had a fleet of 12 ships operating in the Atlantic, the Mediterranean and later in the North Sea. These ships, sailing under neutral colours, were always accompanied by the committee's agents. The ships owned by the foundation ("Caritas I," "Caritas II," "Henry Dunant") or chartered by it made in all 350 round trips and carried 202,965 tons of relief supplies between April 1942 and Dec. 31, 1946.

This cargo represented tonnage equal to that carried by 20,000 railway cars or 500 trains of 40 cars each.

Special Problems.—Total warfare called in question the fundamental principles embodied in the Red Cross conventions and the international humanitarian agreements. Unforeseen problems and complex situations arose which were not provided for, but had to be dealt with as they presented themselves, sometimes on a vast scale and with extreme urgency.

Breaches alleged by one party were communicated to the other by the committee acting as an intermediary between Red Cross societies, the latter being requested to inform their respective governments. The committee received many appeals to investigate and protest against alleged breaches of the rules of war and international law, but was unable on principle to entertain any such application, unless it emanated from all the governments concerned. On the other hand, the committee made spontaneous appeals to belligerent governments in behalf of war victims and in support of humanitarian principles, such action on its part being implied in its function as guardian of essential Red Cross principles.

During World War II, the committee's main task in this field was to secure progressive improvement in the implementing of the conventions, especially as regards the treatment of prisoners of war. To this end, the committee made almost daily application to the detaining powers.

While the Tokyo draft paved the way for the protection of interned enemy aliens, the civilian populations subjected to evacuation, deportation and the rigours attending military occupation remained outside the scope of existing conventions. As to concentration camps, it should be stressed that the committee had no legal basis whatever in international law which could enable it to intervene. These camps were regarded by the detaining authorities as a purely internal affair, and remained absolutely closed to the committee's delegates. Repeated applications to the authorities, however, enabled the committee, in the autumn of 1943, to send food parcels to civilian detainees whose exact addresses were known. During the last days of the war, several of the committee's delegates managed to enter certain concentration camps and succeeded at great personal risk in saving the lives of many thousands.

Two chief belligerents, the U.S.S.R. and Japan, had not ratified the Geneva Prisoner of War convention of 1929. Despite constant efforts during several years, the committee was unable to bring about agreements between Russia and Germany which would have allowed it to forward relief supplies to prisoners of war of either country detained by the other. In the far east, the greatest obstacles were raised to any systematic relief work by Geneva, and the committee's delegates had access only to a limited number of camps in Japan proper, Shanghai and Hong Kong.

After World War II.—Although its wartime services were gradually closing down, the committee was still engaged at mid-century in the following tasks:

1. Aid and protection for many prisoners of war and civilian internees who were detained, despite the close of hostilities and steps in view of their repatriation. This department was particularly active until the end of 1948. The number of reports on visits to prisoner-of-war camps after the armistice in Europe was nearly 2,500.

2. Aid to civilian populations suffering from the consequences of war.

3. Preparatory work for the revision of the Geneva conventions and the establishment of a new convention for the protection of civilians in time of war. This work included the meeting in Geneva of a preliminary Red Cross conference (July-August 1946) and of government experts (April 1947). The drafts prepared by the committee were approved, after slight amendment, by the 17th International Red Cross conference (Stockholm, Swed., Aug. 1948) and were subsequently accepted as a working document by the diplomatic conference of government delegates in Geneva (April 20-August 12, 1949). The Geneva conventions of Aug. 12, 1949 (for the amelioration of the condition of the wounded and sick in armed forces in the field; for the amelioration of the condi-

tion of the wounded, sick and shipwrecked members of armed forces at sea; relative to the treatment of prisoners of war; relative to the protection of civilian persons in time of war), were signed by 63 states.

4. The committee's subsequent interventions were in connection with events in Indochina, Indonesia, Kashmir, Greece, Palestine, Bengal and Korea. (M. H.)

LEAGUE OF RED CROSS SOCIETIES

The League of Red Cross Societies was formed in 1919 on the proposal of H. P. Davison, president of the War Council of the American Red Cross, by the Red Cross societies of France, Great Britain, Italy, Japan and the United States, to develop and intensify the humanitarian activities of the Red Cross in time of peace. By 1951 the league included 68 national Red Cross societies. Its statutes defined among its duties the following:

To act as a permanent liaison agent between national Red Cross societies.

To co-operate in all spheres of their work, especially for the improvement of health, the prevention of disease and the mitigation of suffering.

To represent and to speak for the national societies on the international level in accord with resolutions adopted by the board of governors.

To encourage and facilitate the establishment and the development of the activities of national societies.

To be the guardian of the integrity and interests of the member societies.

The league has a board of governors comprising one representative of each member society, and the board, when not in session, delegates its authority to an executive committee consisting of the chairman and vice-chairmen of the board, together with 12 other societies designated by the board. The board meets biennially and the executive committee at least twice a year. The expenses of the league are met by the voluntary contributions of member societies.

The international activities of the league are supervised by the chairman of the board of governors and carried out by an international secretariat with headquarters at Geneva. In addition to the various branches of the secretary-general's office, there are technical divisions on disaster relief, health, nursing, social service and Junior Red Cross corresponding to the principal peace-time activities of member societies.

The foundation of the league preceded by a few weeks the signing of the covenant of the League of Nations, of which article 25 read as follows:

The Members of the League agree to encourage and promote the establishment and co-operation of duly authorized voluntary national Red Cross organizations having as purposes the improvement of health, the prevention of disease and the mitigation of suffering throughout the world.

This confirmation in the covenant of the central points in the league's program was indicative of the widespread sentiment which caused the national Red Cross societies after World War I to extend their activities to the relief of all preventable suffering. The most immediate tangible result of this decision, and of the consequent activities of the League of Red Cross Societies, was the extension of the Red Cross movement to many countries where it had not previously penetrated—in particular to Latin America. There the association of the Red Cross with war had not found favour, but the idea of an international movement grouping the principal elements that sought to protect mankind against its natural enemies in time of peace made an immediate appeal.

Parallel with this growth in the number of societies came an increase in the Red Cross membership. By the early 1950s it was estimated that the number of Red Cross members in the world (including junior members) totalled 100,000,000.

Since the league functions essentially as a clearinghouse, to enable the national Red Cross societies to use each other's experience and to co-operate readily when need arises, the secretariat has given special attention to creating opportunities for frequent and regular contact between Red Cross representatives from different countries. In 1922 a program of study visits was begun under which delegates visit the headquarters of the league and the headquarters of such national societies as can readily afford facilities

for the study of the particular phase of Red Cross activity in which they are interested. This system is supplemented by regular visits by officers of the secretariat to the headquarters of the national societies. Still more important was the establishment of regional conferences. The Red Cross societies of the far east were first brought together in conference in Bangkok, Thai, in 1922 and again at Tokyo in 1926. The first regional conference for central and eastern European societies was held in Warsaw (Warszawa), Pol., in 1923, the second in Vienna, Aus., two years later and, after World War II, in Belgrade, Yugos., in 1947. Inter-America conferences started in Buenos Aires, Arg., in 1923. These meetings facilitate exchange of views and techniques concerned with problems common to the geographic, economic and social conditions of the respective countries and make possible collective action toward the solution of problems which transcend political boundaries.

The Relief Bureau.—The activities of the league in the technical fields already referred to (disaster relief, health, nursing, social service and Junior Red Cross), led to steady developments, especially in the improvement of standards. The important place of relief, especially disaster relief, in the league program can be attributed in large measure to the creation in 1924 of a special relief division which enabled Red Cross societies to handle disaster relief problems in their respective countries with less outside help. Nevertheless, in major natural disasters when outside help is requested, the necessary appeal is issued and the resultant relief activities co-ordinated by the league either on its own responsibility or in conjunction with the International Committee of the Red Cross. The first such joint appeals were occasioned by the Russian famine of 1921 and in connection with earthquakes in Iran, Japan and Central America. During World War II the magnitude of the distress and the extent of relief made available by national societies and other organizations caused the two international organizations of the Red Cross to create a Joint Relief Bureau. In 1951 the league appeal on behalf of the victims of the floods in the Po river valley, Italy, yielded more than \$1,000,000 in money or commodities given by member societies.

The Health Bureau.—The Health Bureau of the league secretariat after World War II acted primarily in the co-ordination of the medical and public health activities of the national societies and in providing health education materials. In 1951 priority was given to first aid, accident prevention, blood banks, standardization of blood transfusion equipment, tuberculosis control, maternal and child health, mental health and the training of health teachers. Co-operative relations existed with the World Health organization of the United Nations, the United Nations International Children's Emergency fund, the International Union Against Venereal Diseases, the International Blood Transfusion society, the International Union for Child Welfare and other governmental and intergovernmental agencies.

Nursing and Social Service Bureau.—This bureau, whose nursing activities are guided by an advisory committee composed of world leaders in the field, was set up originally in 1919 as a nursing bureau; in 1951 steps were taken to include a social service section. From its inception the bureau has assisted national societies to develop their public health or visiting nurse programs, acting in various ways as a co-ordinating agent. Higher standards for nurse training were developed and programs to include instruction in home care of the sick were extended. A significant contribution was made when the league established an international nursing centre in London in 1920 with the co-operation of Bedford College for Women and the College of Nursing.

Under the auspices of the Florence Nightingale foundation, sponsored in part by the league and with the collaboration of the British Red Cross society, graduate nurses from all over the world were given supplementary training. In 1944 responsibility for the centre was transferred to the International Council of Nurses but with the league represented on the governing body. The Nursing and Social Service Bureau set up an extensive information service, including documents collected or compiled for the use of national societies, and introduced a quarterly in English, French, German and Spanish. It also helps select candidates for Red Cross scholarships and study visit grants and helps arrange suitable training for accepted candidates. A priority program in 1951 was guidance in the organization of Red Cross nursing schools, in the training of nurses' aides, the teaching of home nursing and the enrolment of qualified nursing personnel.

Junior Red Cross Bureau.—This bureau co-ordinates and promotes the work of Junior Red Cross sections in national societies throughout the world. By the early 1950s there were such sections in 60 countries with more than 40,000 members and many of those sections were located in the Red Cross of the elementary and secondary schools. In others, the membership continued to be maintained in units outside the schools. Through a newsletter published in four languages assistance was being given to the organization and content of Red Cross activities appropriate for the several age groups and for adaptation to the needs, resources and cultures of the different countries. School correspondence, albums and art exchanges were facilitated.

Office of International Relations.—This office was established so that the secretariat co-operative relationship with international governmental organizations with objectives related to Red Cross activities, such as the World Health organization, United Nations Educational, Scientific and Cultural organization, Food and Agriculture organization, Refugee organization, International Children's Emergency fund, etc.

NATIONAL RED CROSS SOCIETIES

The national Red Cross societies were originally constituted in most countries to support and assist the army and navy medical services in time of war. Charters granted them by governments, public demand or the absence of other resources to meet great social needs caused them to widen their activities. A national Red Cross society, to obtain official recognition, was required to fulfill the following conditions:

The government of its country must have adhered to the Geneva conventions; the society must have been recognized by its legal government as an auxiliary of the public authorities in the sense of the Geneva conventions; it must adopt the name and emblem of the Red Cross (except in Mohammedan countries the Red Crescent, and in Iran the symbol of the Red Lion and Sun); its activity must extend throughout the country and its dependencies; its membership must be open to all citizens of the country irrespective of sex, politics or religion; and, finally, it must undertake to maintain regular contact with the other national societies and with the International Committee of the Red Cross at Geneva. Only one national Red Cross society may be recognized in each country. Each national society is directed by a central committee and includes a suitable number of regional and local committees which assist the central committee and ensure co-operation from all sections of the country. In most cases there are general meetings once a year of delegates from each local branch.

National Red Cross societies are autonomous and independent within their own territory. The first national Red Cross societies came into existence in Europe immediately following the Geneva conference of 1863, and by 1951 there were 68, with headquarters and founding dates as follows:

Albanian Red Cross; Tirana (Tirane); 1921.
American National Red Cross; Washington, D.C.; 1882.
Argentine Red Cross; Buenos Aires; 1880.
Australian Red Cross; Melbourne; 1914.
Austrian Red Cross; Vienna; 1867.
Belgian Red Cross; Brussels; 1864.
Bolivian Red Cross; La Paz; 1917.
Brazilian Red Cross; Rio de Janeiro; 1908.
British Red Cross society; London; 1870.
Bulgarian Red Cross; Sofia; 1885.
Burma Red Cross society; Rangoon; 1937.
Canadian Red Cross society; Toronto; 1866.
Chilian Red Cross; Santiago de Chile; 1903.
Chinese Red Cross society; Peking; 1904.
Colombian Red Cross society; Bogota; 1915.
Costa Rican Red Cross; San Jose; 1885.
Cuban Red Cross society; Havana; 1909.
Czechoslovak Red Cross; Prague; 1919.
Danish Red Cross; Copenhagen; 1871.
Dominican Red Cross; Ciudad Trujillo; 1927.
Ecuadorian Red Cross; Quito; 1923.
Egyptian Red Cross; Cairo; 1922.
Ethiopian Red Cross; Addis Ababa; 1935.
Finnish Red Cross; Helsinki; 1920.
French Red Cross; Paris; 1864.
Greek Red Cross; Athens; 1877.
Guatemalan Red Cross; Guatemala; 1933.
Haitian Red Cross; Port au Prince; 1932.
Honduran Red Cross; Tegucigalpa; 1937.
Hungarian Red Cross; Budapest; 1879.
Icelandic Red Cross; Reykjavik; 1878.
Indian Red Cross society; New Delhi; 1919.
Indonesian Red Cross; Jakarta (Batavia); 1945.
Iranian Red Lion and Sun society; Tehran; 1925.
Iraq Red Crescent society; Baghdad; 1932.
Irish Red Cross; Dublin; 1930.
Italian Red Cross; Rome; 1864.
Japanese Red Cross society; Tokyo; 1877.
Jordanian Red Crescent society; Amman; 1947.
Lebanese Red Cross; Beirut; 1945.
Liechtenstein Red Cross; Vaduz; 1945.

Luxembourg Red Cross; Luxembourg; 1914.
Mexican Red Cross, Mexico, D.F.; 1907.
Monacan Red Cross; Monaco; 1948.
Netherlands Red Cross; The Hague; 1867.
New Zealand Red Cross society; Wellington; 1915.
Nicaraguan Red Cross; Managua, D.N.; 1934.
Norwegian Red Cross; Oslo; 1865.
Pakistan Red Cross society; Karachi; 1947.
Panama Red Cross; Panama; 1917.
Paraguayan Red Cross; Asuncion; 1910.
Peruvian Red Cross society; Lima; 1870.
Philippine National Red Cross; Manila; 1947.
Polish Red Cross; Warsaw; 1919.
Portuguese Red Cross; Lisbon; 1865.
Rumanian Red Cross society; Bucharest; 1876.
Salvadorian Red Cross; San Salvador; 1885.
South African Red Cross society; Johannesburg; 1913.
Spanish Red Cross; Madrid; 1864.
Swedish Red Cross; Stockholm; 1865.
Swiss Red Cross; Berne; 1866.
Syrian Red Cross; Damascus; 1947.

In the course of years, a few societies ceased to exist where states in which they operated lost sovereignty, or where others had federated into a single society, following political changes.

War Work.—The discharge by national societies of their primary duty as auxiliaries to the medical services of the armed forces began early. The first opportunity for the relief of the wounded in Red Cross societies occurred in the Dano-Prussian War of 1862. In the Seven Weeks' War of 1866, the Franco-German War of 1870-71, the Russo-Japanese War of 1904-05 and the Balkan Wars of 1912-13 the Red Cross societies of belligerent countries provided ambulances, hospitals and medical and nursing personnel to the combatant forces.

World War I naturally led to a vast expansion of Red Cross activity. The American Red Cross alone mobilized 33,000 nurses, 55,000 nurses' aides, 100,000 volunteer helpers, set up 50,000 hospitals, etc., for U.S. troops. The British Red Cross in collaboration with the Order of St. John of Jerusalem and the dominion societies, provided trained nurses, voluntary aid detachments, ambulances and hospitals wherever British forces were engaged. Motor ambulance convoys were organized by the British Red Cross for the evacuation of wounded, in addition to ambulance trains (in Mesopotamia) motor ambulance launches. Similar energy was shown by the Red Cross societies of other belligerents, notably the French, German, Belgian, Italian, Austro-Hungarian, Russian, Serbian and Turkish societies. The Red Cross societies of neutral countries (Switzerland, the Netherlands, Sweden, Denmark, Norway and Spain) also provided assistance to prisoners of war; hospital facilities for serious cases of wounds and diseases, and food for the occupied territories.

In World War II, the work of the Red Cross societies again increased enormously. Although the activities were generally within the categories of World War I, many adaptations to a more total form of war were made. For instance, in World War II, the United States armed forces, not the American Red Cross as in World War I, operated their own hospitals and maintained their own nursing services. However, 70,000 nurses were assigned and certified to the military by the American Red Cross. The civilian service of World War I developed by the American Red Cross in World War II into nearly 1,000 overseas clubs, many of which, in addition to recreation facilities, offered meals and billets. The total expenditures by the national organization from 1919 to 1945, not including the chapters, for services to the armed forces alone amounted to \$365,816,818. Another new service was the blood plasma program, to which the American people gave 13,000,000 pints of blood for their fighting forces.

Again in World War II the British Red Cross and the Order of St. John of Jerusalem operated as a joint war organization and their welfare workers served with British forces in all theatres of operation. Home services were adapted and increased to the needs of the moment. County committees and requests for conscripts, items for hospitalized sailors, soldiers and airmen. Hundreds of thousands were trained in first aid, many of whom joined the Air Raid Precaution organization. Although originally formed to relieve suffering among the sick and wounded in the fighting forces, the British Red Cross in 1940 extended many of its activities to civilian victims of the war. Outstanding among its many activities was packing parcels for the 180,000 prisoners of war who received them regularly. In all their services for prisoners of war through the International Committee of the Red Cross, the British Red Cross and the societies of the dominions in close co-operation with the American Red Cross and the societies of the allied nations.

After World War II.—The extent of suffering following World War II brought into being intergovernmental agencies, bringing aid by governments, such as the United Nations Relief and Rehabilitation

woodland animal, the red-deer in Britain is now confined to open mountain-sides in the highlands of Scotland, Exmoor and a few other localities, and to parks; as a result, there has been a decided decline in the size and condition of the Scottish animals, which cannot compare with those from the Continent. (See DEER.)

REDDITCH, a town and urban district in Worcestershire, England, 15½ mi. S. of Birmingham by the L.M.S.R. Pop. (est. 1938) 22,580. Area, 18.8 sq.mi. It is the centre for the manufacture of needles, fishhooks and fishing tackle; and there is a large motorcycle and cycle works.

REDESDALE, JOHN FREEMAN-MITFORD, BARON (1748-1830), English lawyer and politician, younger son of John Mitford (d. 1761) and brother of the historian William Mitford, was born in London on Aug. 18, 1748. Having become a barrister of the Inner Temple in 1777, he wrote *A Treatise on the Pleadings in Suits in the Court of Chancery by English Bill*, which has been reprinted several times. In 1788 Mitford became M.P. for Beer-alston in Devon, and in 1791 he introduced the important bill for the relief of Roman Catholics, which was passed into law. In 1793 he became solicitor-general, becoming attorney-general six years later, when he sat for East Looe, in Cornwall. In Feb. 1801 he was chosen speaker of the House of Commons. A year later, he was appointed lord chancellor of Ireland with the title of Baron Redesdale. Being an outspoken opponent of Roman Catholic emancipation, Redesdale was unpopular in Ireland. In Feb. 1806 he was dismissed on the formation of the ministry of Fox and Grenville. Although Redesdale declined to return to official life, he was an active member of the House of Lords both on its political and its judicial sides. He died on Jan. 16, 1830.

See O. J. Burke, *History of the Lord Chancellors of Ireland* (Dublin, 1879); J. R. O'Flanagan, *Lives of the Lord Chancellors of Ireland* (1890); Sir J. Barington, *Personal Sketches of His Own Times* (1869); Sir S. E. Brydges, *Autobiography* (1834); and C. Abbot, *Lord Colchester, Diary and Correspondence* (1867).

RED INDIANS; see NORTH AMERICA: Ethnology.

RED JACKET (Sagoyewatha—"the who keeps them awake") (c. 1751-1830) was a Seneca Indian chief born near Geneva, N.Y., about 1751. He was an eloquent orator—whence his Indian name—and possessed considerable influence over his people. He fought for the British during the Revolution and because of his ability as a runner was a favourite among the officers, one of whom presented him with a heavily embroidered red coat. This made him conspicuous among his people and he was henceforth known as Red Jacket. He first appeared as a conspicuous figure when he made a notable speech in opposition to the treaty which was signed at Ft. Stanwix in 1784 by the United States and the Six Nations. In 1792 he went to Philadelphia, then the capital, to conclude a treaty of friendship with the United States, and President Washington presented him with a medal. Under his leadership the Senecas allied themselves with the Americans against the British in the War of 1812. Red Jacket understood the whites well and became more and more hostile to them as he realized their overwhelming power. "You are a kind-hearted people, seeking your own advantages," he said in one of his speeches. He tried to consolidate his people and preserve their ancient ways and rites, but by his stand only lost his leadership. He died in Seneca village, N.Y., on Jan. 20, 1830.

See J. Hubbard, *An Account of Sagoyewatha* (1886); Buffalo Historical Society, *Red Jacket* (1885).

REDLANDS, a city of San Bernardino county, Calif., U.S., at the foot of the San Bernardino mountains, 65 mi. E. of Los Angeles, on federal highways 70 and 99. It has an airport and is served by the Pacific Electric, the Santa Fe and the Southern Pacific railways and by motor-coach lines in all directions. The population in 1950 was 18,411 and in 1940 was 14,324 by federal census.

It lies at an altitude of from 1,300 to 2,100 ft., surrounded on three sides by peaks more than 10,000 ft. high (Mts. San Jacinto, San Antonio or "Old Baldy" and San Geronimo or "Grayback") in the midst of the largest navel orange growing district in the world. From 4,500 to 7,000 carloads of citrus fruit are produced and shipped from Redlands each season. The University of

Redlands (opened in 1907) has an enrolment of more than 1,100. A settlement called "Lugonia" was established there in 1874 but the present city was founded in 1887 by New Englanders and incorporated in 1888. The city is governed by an elected board of five trustees.

REDLICH, JOSEPH (1869-1936), Austrian historian and politician, was born in Göding, Moravia, on June 18, 1869. He studied jurisprudence and history in Vienna, travelled extensively, especially in England, and in 1901 published his first work, *Die englische Lokalverwaltung* (Local Government in England, 1904). He afterwards became Professor at Vienna University, and sat in the Austrian parliament till 1911 as deputy for his birthplace. Both in the Austrian parliament in Vienna and the Moravian diet he did much to further the idea of an understanding between the German and Czech races. In 1905 he published another study of English political life: *Recht und Technik des englischen Parlamentarismus* (1905), Eng. trans., *The Procedure of the House of Commons*, 3 vols. (1907), a standard work on the subject and indispensable to the student. During the World War he was politically active, and in 1918 was appointed minister of Finance in the Lammasch Cabinet. He then retired from active politics, to produce *Das österreichische Staats- und Rechtsproblem* (vol. 1 1920, vol. 2 1926), a history of Austrian domestic policy from 1848 onward. His other works include *Das Wesen der österreichischen Kommunalverfassung* (1910); *The Common Law and the Case Method in American University Law Schools* (1914); *Österreichische Regierung und Verwaltung im Weltkrieg* (English and German, 1925) and a biography, *Franz Joseph von Österreich* (1928). Redlich's attitude was usually rather that of a student of political theory and practice than of a pure historian, and his works were apt to be too voluminous to be easily read; but they were founded on encyclopaedic knowledge, most carefully presented, and were exhaustive.

RED LODGE, a city of southern Montana, U.S.A., 15 mi. from the Wyoming state line; the county seat of Carbon county. It is on federal highway 12 and is served by the Northern Pacific railway. Pop. (1950) 2,715; (1940) 2,950. It is the centre of one of the principal coal mining regions of the state, and there are also gold and silver mines and oil and gas fields in the vicinity. The Beartooth National forest lies a few miles to the west.

REDMAYNE, SIR RICHARD AUGUSTINE STUDDERT (1865-), K.C.B. (1914), was born at Gateshead-upon-Tyne, on July 22, 1865, and educated privately and at the Durham College of Science, Newcastle. In 1883 he became under-manager at a colliery firm in Durham, and eight years later went to South Africa. On his return in 1893 he was appointed manager of the Seaton Delaval collieries, Northumberland (1893-1902). He then obtained an appointment at Birmingham university, as professor of mining. He acted as chairman on numerous Government committees on questions affecting the mines, and in 1908 was appointed chief inspector of mines, a post which he held until 1920. He was chairman and governor of the Imperial-Mineral Resources bureau (1918-25), and chairman of the advisory council on minerals to the Imperial institute (1925-35). His writings include *Men, Mines and Memories* (1942), *The Problem of the Coal Mines* (1945) and many official reports on mining.

REDMOND, JOHN EDWARD (1856-1918), Irish politician, son of W. A. Redmond, M.P., was born at Ballyrent. He was educated at Trinity college, Dublin, and was called to the bar at Gray's Inn in 1886, and subsequently to the Irish bar, though he never practised. He was a clerk in the vote office of the House of Commons before he entered parliament in 1881 as member for New Ross. From 1885 to 1891 he represented North Wexford. As party whip he rendered great service to the Irish members by his thorough grasp of the procedure of the House. At the time of the rupture of the Irish party consequent on the Parnell scandals, Redmond was the most eloquent member of the minority who continued to recognize his leadership, and in 1891 he became the accredited leader of the Parnellites. In 1900 the two nationalist parties were amalgamated under his leadership. He contested Cork unsuccessfully in 1891, but was elected for Waterford, where he was re-elected in 1906. (For the political

events under his leadership of the Irish parliamentary party up to 1910, see IRELAND: History; ENGLISH HISTORY, etc.).

Redmond obtained for the first time a position of real power in parliament after the general election in Jan. 1910. Though he had amalgamated the two Irish Nationalist parties under his own lead in 1900, he had never hitherto been able, owing to the large Unionist majority of 1900 and the Liberal majority of 1906, to hold that balance of power in the House of Commons which had proved such a formidable weapon in the hands first of O'Connell and then of Parnell. But the reduction of the Liberal forces in Jan. 1910 made it impossible that Asquith's Government should long continue unless it found favour with Redmond.

The first use which he made of this new authority was to insist that Lloyd George's famous budget of 1909, on which the dissolution had turned, should be postponed till after the constitutional resolutions directed against the House of Lords—his one object being to remove the veto of the Upper House, which was the main barrier against Home Rule. This order of procedure was also demanded by the Labour party and by the Radicals; and the Government complied. But Redmond pressed further for an assurance that the royal prerogative would be at the prime minister's disposal to overbear any rejection by the Lords of the veto resolutions. He was impatient at the constitutional conference called in the summer at the beginning of King George's reign to endeavour to discover a solution by consent, and went to America to secure sympathy and funds. The conference having broken down, he conducted a strenuous campaign on behalf of the ministerial programme for the second general election of the year, in spite of a harassing movement on his flank by a small party of independent Nationalists under O'Brien and Healy, who accused him of having sold the Irish vote to the government.

When the result of the polling had confirmed Redmond in his tenure of the balance of parliamentary power, he forwarded the progress of the Parliament bill in 1911 by the steady vote of his party. In the autumn he was regularly consulted on the details of the forthcoming Home Rule bill, and when the bill was introduced, in April 1912, he procured its enthusiastic acceptance from a nationalist convention in Ireland. His speeches during its passage through parliament were, on the whole, moderate; he disclaimed separation but denounced any attempt to take Ulster out of the bill as a mutilation of Ireland. In token of the union of feeling between Nationalists and Liberals, he attended the meeting of the National Liberal Federation at Nottingham in Nov. 1912, and spoke for the first time on the same platform as Asquith. When the determined attitude of Ulster began to suggest to the Liberals the advisability of compromise, Redmond was very loth to agree, denouncing the Unionists and Ulster as engaged in "a gigantic game of bluff and blackmail." He insisted that Asquith's county option scheme was the extreme limit of concession. He was being pressed in Ireland by the rising power of Sinn Féiners and other extremists who had raised, in reply to Ulster, a great body of 100,000 nationalist volunteers, over whom Redmond only obtained control in June 1914 after a sharp struggle. Nevertheless he took part, at the end of July in the abortive Buckingham Palace Conference.

Then came the World War, and in the debate succeeding Sir E. Grey's famous declaration on Bank Holiday, Aug. 3, Redmond created a profound sensation by a speech in which he declared that the events of recent years had completely altered the Nationalist feeling towards Great Britain. The Government, he said, might withdraw its troops from Ireland, whose coasts would be defended by her own sons, Nationalist volunteers joining with Ulster volunteers in the task. This generous attitude was met by the decision of the Government to pass the Home Rule bill into law, suspending its operation till after the war. Redmond took an active part in promoting recruiting in Ireland, and stood on the platform in Dublin Mansion House on Sept. 25 by the side of the prime minister and the lord lieutenant. Unfortunately, his efforts were only moderately successful, but he refused Asquith's offer to join the first Coalition Government, and he successfully opposed all attempts to apply conscription to Ireland. It was a stunning blow to him when the smouldering

dissatisfaction of southern Ireland broke out into a blaze in the Dublin rebellion of Easter 1916. He expressed in the House of Commons his detestation of the crime, and lent his assistance to the attempt which was made by the Government in the summer through Lloyd George to arrange an agreed settlement of the Irish question.

But the effort failed; Duke, a Unionist, was appointed chief secretary; and Redmond treated the whole transaction as a fresh outrage on Ireland, moving on Oct. 18 a resolution (which was, of course, rejected) charging ministers with maintaining a system of Government in that country inconsistent with the principles for which the Allies were fighting in Europe. Next year he threatened a return of his party to the old obstructionist opposition; but when in May 1917 Lloyd George, as prime minister, suggested an Irish convention to produce a scheme of self-government, Redmond agreed; and in the convention he played a conciliatory part. During its sittings, however, his health failed. He died of heart failure in London on March 6, 1918.

See I. G. Redmond Howard, *John Redmond* (1910); *Home Rule: Speeches of John Redmond*, M.P., edit. by R. Barry O'Brien (1919); S. Gwyn, *John Redmond's Last Years* (1919).

REDMOND, WILLIAM HOEY KEARNEY (1861-1917), younger brother of John Redmond (q.v.), intended, as a young man, to adopt the army as his profession, and in 1881 he was a lieutenant in the Co. Wexford militia battalion of the Royal Irish regiment. But he resigned his commission to take part in the Land League movement and was imprisoned as a "suspect" in Kilmainham. He was returned for Wexford borough in 1883, and sat in parliament, though for different constituencies, from that time till his death. He was of an ardent and ebullient temper, which resulted in his spending three months in Wexford gaol in 1888 for inciting, at an eviction, to resistance to the sheriff, and in many agitated scenes at different times in the house of commons, where, however, he was personally very popular. Like his brother, in the Nationalist split he adhered to Parnell, and also like his brother, on the outbreak of World War I he instantly recognized the duty of Ireland to fling herself into it on the side of the Allies. Though 53 years old he joined at once the Irish division, receiving a commission in the Royal Irish regiment. He was promoted major for services at the front and mentioned in despatches. In his intervals of service he made two thrilling speeches in the house of commons, advocating conciliation and a new start between England and Ireland. He died of wounds in France June 7, 1917.

See Memorial Volume, *Major William Redmond* (1917); W. H. K. Redmond, *Trench Pictures from France* (1917); T. P. O'Connor, *The Parnell Movement* (1886).

RED OAK, a city of southwestern Iowa, U.S.A., 50 mi. S.E. of Omaha, Neb., on the Nishnabotna river, federal highway 34 and the Burlington railroad; the county seat of Montgomery county. Pop. (1950) 6,451. Manufactured products include batteries, furnaces, concrete pipe, water tanks, flour and feeds; popcorn and alfalfa are processed. The city was founded in 1855 and incorporated in 1869.

It has a council form of government.

REDON, a town of western France, capital of an *arrondissement* in the department of Ille-et-Vilaine, 45 mi. S.S.W. of Rennes by rail. Pop. (1946) 5,710. Redon grew up round a monastery founded in the 9th century. In the 14th century the abbey Jean de Tréal surrounded the town with walls, of which a portion remains. Redon stands on the right bank of the Vilaine, above the confluence of the Oust and the canal from Nantes to Brest. The church of St. Sauveur, a former abbey, has a square Romanesque central tower with rounded angles. A fine 14th century tower with a stone spire stands isolated from the church, from which it was separated by fire in 1782. The 13th century choir, with ambulatory and radiating chapels, is notable.

REDONDA, an island in the British West Indies. It is a dependency of Antigua, Leeward Islands, and lies 25 mi. S.W. of it, in 25° 6' N. and 61° 35' W. It is a rocky mountain, rising abruptly from the sea to a height of 1,000 ft.; area $\frac{1}{2}$ sq. mi. Phosphate of alumina (discovered in 1865) was formerly exploited,

with an annual output of about 7,000 tons.

REDONDO BEACH, a city of Los Angeles county, California, U.S.A., on the Pacific ocean, 19 mi. S.W. of Los Angeles and 10 mi. N.W. of the Los Angeles and Long Beach harbour. It is on federal highway 101 and is served by two bus systems. Pop. 25,208 in 1930 and 13,097 in 1940 by the federal census. In a natural amphitheatre facing the ocean, the city slopes gently upward from its silvery crescent-shaped beach to an elevation of 250 ft., with Los Angeles and the San Gabriel mountains in the background. It is a pleasure and health resort and a residential centre for workers in the adjacent oil fields and industrial districts. The city owns a mile of the water front, including Moonstone beach. A harbour enclosed by a breakwater provides yacht anchorage. The city was incorporated in 1892.

REDPOLE, the name given to several birds of the finch family (*Pringillidae*), allied to the linnet (*g.v.*), and possessing a reddish head. The best known is the lesser redpoll (*Carduelis linaria*). The mealy redpoll is a subspecies with a more northern range, visiting England in the winter. The type ranges over the whole of the north temperate zone. There are three additional subspecies in America, but these rarely reach the United States.

RED RIVER, the name of two American rivers, one emptying into the Mississippi near its mouth, and the other emptying into Lake Winnipeg.

1. The Red river, sometimes called the Red River of Louisiana, is the southernmost of the large tributaries of the Mississippi. It rises in northern Texas, in the northern part of the High Plains, or Llano Estacado, flows east by south in Texas, between Texas and Oklahoma, and to Fulton, in south-western Arkansas, then turns south-east and continues in a general south-easterly direction through Louisiana to the bank of the Mississippi, where it discharges partly into the Mississippi and partly into the Atchafalaya. Its length is estimated at 1,200 m. or more; its drainage basin has an area of at least 90,000 sq.m.; and its discharge ranges from 3,500 cu.ft. to 180,000 cu.ft. per second. Its middle and lower course is laden with a reddish silt from which it takes its name. From an elevation on the High Plains of about 2,450 ft., the river plunges into a canyon which is about 60 m. long and has nearly perpendicular walls of sandstone and gypsum formation 500 to 800 ft. high. Immediately below the canyon the river spreads out over a broad and sandy bed and flows for about 500 m. through a semi-arid plain. It narrows on entering the alluvial bottom lands, through which it pursues a sluggish and meandering course for the last 600 m. A shifting channel, deposits of silt and fallen trees have always hindered navigation. In 1828 the trees which the river had felled formed the great "Red River raft" extending from Loggy Bayou, 65 m. below Shreveport, Louisiana, to Hurricane Bluffs, 27 m. above Shreveport. Congress began in that year to make appropriations for the removal of the raft, and by 1841 Henry M. Shreve had opened a channel. The river was neglected from 1857 to 1872 and another raft, 32 m. in length, formed above Shreveport. A channel was opened through this in 1872-73, and the complete removal of the obstruction a few years later so improved the drainage that a large tract of waste land was reclaimed. In its course through Louisiana the river has built up a flood-plain with silt deposits more rapidly than its tributaries, with the result that numerous lakes and bayous have been formed on either side, and Cypress has been so flooded that boats ply between Shreveport, Louisiana, and Jefferson, Texas, 66 m. apart. The main river is navigable for small draught boats from the mouth to Fulton, Ark., a distance of 508.6 m.; however, there is little commerce above the mouth of the Black.

During the Civil War, in March and April 1864, Major-General Nathaniel P. Banks conducted a combined military and naval expedition up the Red river in an attempt to open a Federal highway to Texas, but on April 8, the vanguard of his army was repulsed with heavy loss at Sabine Cross-Roads by the Confederates under Lieut.-Gen. Richard Taylor and the expedition was abandoned; the gunboats commanded by Rear Admiral D. D. Porter were held above Alexandria by the lowness of the river, but it was flooded by a hurriedly built dam, and they escaped.

See R. B. Marcy and G. B. McClellan, *Exploration of the Red River of Louisiana* (Washington, 1853), and the annual *Reports of the Chief of Engineers of the U.S. Army*.

2. The Red river, commonly called the Red River of the North, rises in the lake region of western Minnesota, not far from the headwaters of the Mississippi, flows north between Minnesota and North Dakota, continues northward through the Canadian province of Manitoba, and discharges into Lake Winnipeg. It has cut a gorge 20 to 50 ft. deep through clay deposits throughout the greater part of its course; it drains a region that is famous for the production of wheat; and much water-power has been developed on its tributaries.

RED RIVER SETTLEMENT, a Scottish colony founded in 1811 near the present city of Winnipeg by a philanthropic Scottish nobleman, Lord Selkirk, who at that time controlled the Hudson's Bay company and received from it a grant of 113,000 sq.mi. in the basin of the Assiniboine and Red rivers. Quarrels soon arose with the French and half-breed employees of the North-West Fur company, and were fostered by its officials. On June 19, 1816, in a fight between the rivals, Governor Semple of the Hudson's Bay company and 20 of his 27 attendants were killed, an affair known as the Battle of Seven Oaks. New settlers were sent by Selkirk, and founded the village of Kildonan, now part of Winnipeg. In 1821 the rival companies united, and in 1836 repurchased from Selkirk's heirs all rights to the territory. In 1821 and in 1835 two forts, known as Lower and Upper Fort Garry, were built to command the junction of the Red and Assiniboine rivers. The purchase in 1869 of the territorial rights of the company by the Dominion of Canada led to a rebellion, and the setting up of a provisional government under Louis Riel, which was dispersed.

BIBLIOGRAPHY.—J. J. Hargrave, *Red River* (1869); George F. G. Stanley, *Birth of Western Canada* (1936); Vera Kelsey, *Red River Runs North* (1951).

REDRUTH, a market town in Cornwall, England, 17 mi. E.N.E. of Penzance, on the G.W. railway. Pop. with Camborne (*g.v.*) 34,920 (1938). It lies high, on the northward slope of the central elevation of the county, with bare rocky moors to the south. It is the chief tin-mining town in Cornwall, and the bulk of the population is engaged in the mines or at the numerous tin-streaming works. A large quantity of the tin is sold by public auction at the mining exchange, the sales being known as tin-ticketings. There are manufactures of safety fuses, breweries, tanning, iron foundries and railway works, and near by are numerous stone quarries. The parish church of St. Uny, of which only the tower is ancient (Perpendicular), stands outside the town to the west, at the foot of Carn Brea. On the summit of this hill, near a small ancient castle, prehistoric remains are traceable.

RED SEA, a narrow strip of water extending south-south-east from Suez to the Strait of Bab el Mandeb in a nearly straight line, and separating the coasts of Arabia from those of Egypt, Nubia and Abyssinia. Its total length is about 1,200 m., and its breadth varies from about 250 m. in the southern half to 130 m. in 27° 45' N., where it divides into two parts, the Gulf of Suez and the Gulf of Aqaba, separated from each other by the peninsula of Sinai. Structurally, the Red sea is part of a great rift-valley system forming one of the most marked features of the earth's crust. The rift valley of the Jordan and the Dead sea is continued southward by the Wadi el Araba, and its submerged southern section gives the Gulf of Aqaba. This well marked north-north-east to south-south-west line meets the north-north-west to south-south-east line, already marked in the Gulf of Suez, and together they form, to the south, the main basin of the Red sea. The rift may be traced still farther southward among the great African lakes.

This great structural depression is probably of Tertiary age, being laid down between two ancient Archaean blocks—Arabia and North Africa. Secondary and Tertiary deposits appear on both flanks in Egypt and Arabia, while Archaean material appears at the surface in many places on the Red sea coast. These extensive earth movements were accompanied by much volcanic activity, traces of which are still evident. A group of volcanic islands occurs in 14° N., and on Jebel Teir, farther north, a volcano has only recently become extinct. The margin of the Red sea

itself consists, on the Arabian side, of a strip of low plain backed by ranges of barren hills of coral and sand formation, and here and there by mountains of considerable height. The greater elevations are for the most part formed of limestones, except in the south, where they are largely volcanic. The coasts of the Gulf of Aqaba are steep, with numerous coral reefs on both sides. On the African side there are, in the north, wide stretches of desert plain, which towards the south rise to elevated tablelands, and ultimately to the mountains of Abyssinia. The shores of the Red sea are little indented; good harbours are almost wanting in the desert regions of the north, while in the south the chief inlets are at Massawa, and at Kamaran, almost directly opposite. Coral formations are abundant; immense reefs, both barrier and fringing, skirt both coasts, often enclosing wide channels between the reef and the land.

Depths.—The mean depth of the Red sea is 267 fathoms. The Gulf of Suez is shallow, and slopes regularly down to the northern extremity of the Red sea basin, which has a maximum depth of 640 fathoms, and then over a shoal of 60 fathoms goes down to 1,200 fathoms in $22^{\circ} 7' N$. The Gulf of Aqaba is separated from the Red sea by a submarine bank only 70 fathoms from the surface, and in $28^{\circ} 39' N$. and $34^{\circ} 43' E$. it attains the depth of 700 fathoms. South of the 1,200-fathom depression a ridge rises to 500 fathoms in the latitude of Jeddah, and, south of this again, a similar depression goes down to 1,190 fathoms. Throughout this northern part, *i.e.*, to the banks of Suakin and Farsan in $20^{\circ} N$, the 100-fathom line keeps to a belt of coral reef close inshore, but in lower latitudes the shallow coral region, 300 m. long and 70 to 80 m. across, extends farther and farther seaward until, in the latitude of Hodeida, the deep channel (marked by the 100-fathom line) is only 20 m. broad, all the rest of the area being dangerous to navigation, even for small vessels. In the middle of the gradually narrowing channel three depressions are known to exist; soundings in two of these are: 1,209 fathoms in $20^{\circ} N$. and 890 fathoms in $16^{\circ} N$, a little to the north of Massawa. To the north-west of the volcanic island of Zebayr the depth is less than 500 fathoms; the bottom of the channel rises to the 100-fathom line at Hanish island (also volcanic), then shoals to 45 fathoms, and sinks again, in about the latitude of Mokha, in a narrow channel which curves westward round the island of Perim (depth 170 fathoms), to lose itself in the Indian ocean. This western channel is 16 m. wide in the Strait of Bab el Mandeb; the eastern channel of the strait is 2 m. broad and 16 fathoms deep. Estimates of the total area of the Red sea vary considerably, but it may be taken at 177,030 sq. st. m. approximately, and the volume at 53,700 cb. st. m. approximately.

Metereology.—In the northern part, down to almost $19^{\circ} N$, the prevailing winds are north and north-west. The middle region, to 14° – $16^{\circ} N$, has variable winds in an area of low barometric pressure, while in the southern Red sea south-east and east winds prevail. From June to August the north-west wind blows over the entire area; in September it retreats again as far as $16^{\circ} N$, south of which the winds are for a time variable. In the Gulf of Suez the westerly, or "Egyptian," wind occurs frequently during winter, sometimes blowing with violence, and generally accompanied by fog and clouds of dust. Strong north-north-east winds prevail in the Gulf of Aqaba during the greater part of the year; they are weakest in April and May, sometimes giving place at that season to southerly breezes. The high temperature and great relative humidity in summer, make it a difficult region for active life.

The mean annual temperature of the surface waters near the head is 77° ; it rises to 80° in about $22^{\circ} N$, to 84° in $16^{\circ} N$, and drops again to 82° at the Strait of Bab el Mandeb. Daily variations of temperature are observable to a depth of over 50 fathoms. Temperature is, on the whole, higher near the Arabian than the Egyptian side, but it everywhere diminishes with increase of depth and latitude, down to 380 fathoms from the surface; below this depth a uniform constant temperature of 70.7° is observed throughout. In the Gulf of Suez temperature is relatively low, falling rapidly from south to north. The waters of the Gulf of Aqaba are warmer towards the Arabian than the Sinai coast; a uniform temperature of 70.2° is observed at all depths below

270 fathoms.

Salinity.—The salinity of the waters is relatively great, the highest reading being 41 per mille (Gulf of Suez), and the lowest 36.5 near Perim island. The distribution is, speaking generally, the opposite to that of temperature; salinity increases from the surface downwards, and from the south northwards, and it is greater towards the western than the eastern side. This statement holds good for the Gulf of Suez, in which the water is much saltier than in the open sea; but in the Gulf of Aqaba the distribution is exceedingly uniform, nowhere differing much from an average of 40 per mille.

The movements of the waters are of great irregularity and complexity, rendering navigation difficult and dangerous. Two features stand out with special distinctness; the exchange of water between the Red sea and the Indian ocean, and the tidal streams of the Gulf of Suez. From the observations of salinity it is inferred that a surface current flows inwards to the Red sea in the eastern channel of the Strait of Bab el Mandeb, while a current of very salt water flows outward to the Indian ocean, through the western channel, at a depth of 50 to 100 fathoms from the surface. In the Gulfs of Suez and Aqaba, almost the only part of the Red sea in which tidal phenomena are well developed, a sharply-defined tidal circulation is found. Elsewhere, the surface movements at least are controlled by the prevailing winds, which give rise in places to complex "transverse" currents, and near the coast are modified by the channels enclosed by the coral reefs. During the prevalence of the north and north-west winds the surface level of the northern part is depressed by as much as 2 feet.

The Red sea was important in Egyptian maritime commerce at least as early as the 2nd millennium B.C. (see QOSER, *Et.*) and it had associations with India early in the 1st millennium B.C. Under the Arabs the Red sea was an important highway of trade with connections to India, Persia and East Africa. This sea helped to keep Islam in touch with the thinkers of the East and with the glories of the ancient world during "the dark ages" in the West; with the revolutions in shipping and movement by sea that followed "the age of discovery" the Red sea seemed to retreat into the background; but with the cutting of the Suez canal (1869) and the shortening of the route to India, Australia and the East, the Red sea not only recovered its former importance but became one of the greatest commercial highways in the world.

REDSHANK, the name of a bird, *Tringa totanus*, so called from the colour of its long legs. In suitable localities it is abundant throughout the greater part of Europe and Asia, retiring southward for the winter, though a considerable number remain along the coasts of some of the more northern countries. The body of the redshank is as big as a snipe's, but its longer neck, wings and legs make it appear larger. Above, the general colour is greyish-drab, freckled with black, except the lower part of the back and a conspicuous band on each wing, which are white, while the flight-quills are black. The bird nests in inland localities as well as by the sea. The males in spring have a beautiful song-flight, rising and falling with quivering wings, and a striking courtship on the ground. They are very pugnacious, fights often continuing for over an hour. The redshank is very wary, and is disliked by shore gunners for giving the alarm to other species. The nest is generally concealed in a tuft of rushes or grass in the swamp whence the bird gets its sustenance, and contains four eggs of a warmly tinted brown with blackish spots or blotches.

The black, dusky or spotted redshank (*T. erythropus*) is a larger and less common bird, and in the greater part of Europe it only occurs on its passage to or from its breeding-grounds, which are south of the Arctic circle. The spot chosen for the nest is

nearly always in forests and at some distance from water. In breeding-dress the head, neck, shoulders and lower parts are black, the back and rump white, while the legs become crimson. At other times of the year the plumage is similar to that of the common redshank and the legs are of the same light orange-red.

REDSTART or FIRETAIL (*Phoenicurus phoenicurus*), a small bird which is a summer visitor to Europe, where it haunts gardens, orchards, and old buildings. Its habit of flitting its red tail, and the white forehead, black throat, and bay breast of the cock are distinguishing features; the hen is more plainly coloured; but the characteristic colouring and action of the tail pertain to her equally as to her mate. The nest is almost always placed in a hole of a tree or building, and contains from five to seven eggs of a delicate greenish blue, occasionally sprinkled with faint red spots. The young on assuming their feathers present a great resemblance to those of the redbreast (*q.v.*) at the same age; but the red tail, though of duller hue than in the adult, forms even at this early age an easy means of distinguishing them. The redstart breeds regularly in all the counties of England and Wales. It also reaches the extreme north of Scotland; but in Ireland it is very rare. It appears throughout the whole of Europe in summer, and is known to winter in the interior of Africa. Several very nearly allied forms occur in Asia; and one, *P. aurea*, is found in Japan. The black redstart (*P. ochurus*) is darker than the preceding, with a more southerly range. Like the last, however, it winters in Africa. It often haunts the vicinity of houses. The males of the black redstart seem to be more than one year in acquiring their full plumage. Allied to the redstarts are the bluethroats (*q.v.*). These groups belong to the subfamily *Turdinae* of the thrushes. The American redstart (*Selophaga ruticilla*) belongs to the purely New World family *Mniotiltidae*, and ranges from Canada (in summer) to Bolivia, but is rare on the Pacific coast. The salmon of the breast, wings, and tail of the male are replaced by yellow in the female. The painted redstart (*S. picta*) has a deep red breast and belly. It inhabits the Mexican plateau, extending north to Arizona and New Mexico.

REDUCTION: *see* OXIDATION AND REDUCTION.

RED WING, a city of Minnesota, U.S., on the Mississippi river, below the mouth of the Cannon and above the head of Lake Pepin; 50 mi. S.E. of St. Paul, county seat of Goodhue county; on federal highways 61 and 53, state highways 19 and 58. It is served by Chicago Great Western and Chicago, Milwaukee, St. Paul and Pacific railways, bus and barge lines. Pop. (1950) 10,645. In 1695 Pierre Charles le Sueur established a post on Prairie Island, 8 mi. above Red Wing, and in 1727 René Boucher built a fort (abandoned in 1755) on the shore of Lake Pepin. A village of the Dakotas had long occupied the site of the city when in 1837 two Swiss missionaries established a mission which they maintained until 1846. In 1848 a second mission was established by the American board. The city was platted in 1853; chartered in 1857. Red Wing is the name of the Dakota chief who settled his people there, and who is buried on the top of Barn bluff. Red Wing produces shoes, leather, pottery, flour, marine motors, etc.

REDWING, a species of thrush (*q.v.*), *Turdus musicus*, a winter visitor to the British Islands, arriving in autumn about the same time as the fieldfare (*q.v.*). It is very similar to the song-thrush, but with a white streak over the eye, and the sides of its body, inner wing-coverts and axillaries reddish-orange. The redwing breeds in colonies in woods in subarctic Europe and Asia to Lake Baikal. In winter it migrates as far south as North Africa and the Himalayas. Its song has often been praised, but is disappointing in comparison with that of the song-thrush or blackbird. In its winter quarters it often gives a peculiar inward song in early spring, while still in flocks. Its nest and eggs resemble those of the blackbird.

REDWOOD, SIR BOVERTON (1846-1919), British chemist, was born on April 26, 1846, and educated at University College school, London. He was trained as a pharmacist, but early specialized in the study of petroleum, becoming in 1869 secretary of the Petroleum association and subsequently studying oil conditions at first hand in many parts of the world (1883-86). He served on several important Government commissions both before

and during the World War. Founder of the Society of Petroleum Technologists, he became its first president 1913-14 and he was also a member of many other societies in pure and applied science. He was knighted in 1905, was made a baronet in 1911 and died in London on June 4, 1919. Redwood wrote widely on his subject, including *Petroleum*, 3 vol. (1913).

REDWOOD (*Sequoia sempervirens*) a valuable, gigantic, coniferous tree extending along the Pacific coastal forests from southern Oregon to near Santa Barbara, California. The largest tree upon which accurate measurements have been made is 364 ft. tall and 12 ft. 7 in. in diameter at breast height. It is seldom found more than 35 mi. inland or above 3,000 ft. in elevation. An unusual feature of this tree is its ability to develop thrifty, vigorous, stump sprouts which attain commercial proportions in a relatively short time. While coppice sprouts of this sort are a common feature of broad-leaved species, their occurrence among conifers is relatively rare. The allied bigtree, *Sequoia gigantea* (syn. *Sequoiadendron giganteum*) also of California (discovered in 1850 in the Sierra Nevada) develops a much more massive bole but not quite the stature of coastal species (*see* SEQUOIA).

REDWOOD CITY, a town of California, U.S.A., on Redwood creek, 27 mi. S. by E. of San Francisco; the county seat of San Mateo county. It is on federal highway 101, and is served by the Southern Pacific Ry. Pop. 25,342 in 1950 by federal census. It was settled about 1856 and incorporated in 1867.

REDWOOD HIGHWAY, an American highway 479 mi. long commencing at San Francisco, Calif., and terminating at Grants Pass, Ore. From Crescent City, Calif., to Eureka, the highway passes close to the Pacific coast, now high up on the cliffs and again down by the sea. It passes through 100 mi. of ancient redwood forests 20 mi. wide, whose trees are 200 and 300 ft. high, very straight, and as much as 30 ft. in diameter. South of Eureka the principal points touched are Fortuna, the Humboldt State Redwood park, Ukiah and Santa Rosa.

RED WOODS, INSOLUBLE. Under this designation, *sanderswood* (*Pterocarpus santalinus*, Tropical Asia), *barwood* (*Baphia nitida*, West Coast of Africa) and *camwood* come into commerce. These closely resemble one another in tinctorial property, and contain colouring matters which are sparingly soluble in water. They may be applied to wool without the aid of a mordant, though in general the material is first dyed and a mordant, usually bichromate of potash, added to the dye-bath. The shade given with *sanderswood* and *barwood* is dull red brown, with *camwood* a more violet tint. Both *sanderswood* and *barwood* still find employment for "topping" indigos, i.e., the indigo-dyed woollen material is treated in a boiling bath with one or other of these dyewoods. Little is known of the chemical structure of the colouring matters of these dyewoods.

REED, JOSEPH (1741-1785), American politician, was born in Trenton, N.J., on Aug. 27, 1741. He graduated at Princeton in 1757, studied law in 1763-65 at the Middle Temple, London, and then practised in Trenton until his removal to Philadelphia in 1770. He was aide-de-camp and military secretary to Gen. Washington in 1775-76, and was adjutant general in 1776-77. In 1777-78 he was a delegate to the Continental Congress. From 1778 to 1781 he was president of the State executive council. During his administration the proprietary rights of the Penn family were abrogated (1779), and provision was made for the gradual abolition of slavery (1780). Reed was elected to Congress in 1784, but died in Philadelphia on March 5, 1785.

The Life and Correspondence of Joseph Reed (Philadelphia, 1874), by his grandson, William B. Reed, is based upon the family papers. It pictures Reed as an heroic patriot and statesman; George Bancroft, on the other hand, in the ninth volume (p. 229) of his *History* (1866) and in *Joseph Reed: an Historical Essay* (1867), pictures him as a trimmer of the most pronounced type. Bancroft withdrew his most specific charge in the 1876 edition of his *History*, in which, however, his tone towards Reed was unchanged.

His grandson, WILLIAM BRADFORD REED (1806-76), graduated at the Pennsylvania university in 1822. He was professor of American history in the University of Pennsylvania in 1850-56, United States minister to China in 1857-58, and in 1858 negotiated a treaty with China, proclaimed in 1860.

REED, THOMAS BRACKETT (1839-1902), American statesman, was born in Portland, Me., on Oct. 18, 1839. He graduated at Bowdoin college in 1860, and in 1865 was admitted to the bar. He was a member of the Maine House of Representatives in 1868-69 and of the State Senate in 1870, was attorney-general of the State in 1870-72, and was city solicitor of Portland in 1874-77. He was a Republican member of the National House of Representatives from 1877 until 1899, of which he was speaker in 1889-91 and in 1895-99. He was a "strong" speaker in his control of the proceedings, and he developed an organized committee system, making the majority of the committee on rules consist of the speaker and chairman of the committees on ways and means and on appropriations. The "Reed rules," drawn up by him, William McKinley and J. G. Cannon, were adopted on Feb. 14, 1890; they provided that every member must vote, unless pecuniarily interested in a measure, that members present and not voting may be counted for a quorum, and that no dilatory motion be entertained by the speaker. His parliamentary methods were bitterly attacked by his political enemies, who called him "Tsar Reed." His rules and methods of control of legislation were adopted by his successors in the speakership, and the power of the rules committee was greatly increased. After the war with Spain Reed broke with the administration on the issue of imperialism. He resigned his seat in 1899 and practised law in New York city. He died in Washington on Dec. 7, 1902. Reed was a remarkable personality, of whom many good stories were told, and opinions varied as to his conduct in the chair; but he was essentially a man of rugged honesty and power.

Reed's Rules were published as a parliamentary manual. He edited with others a *Library of Modern Eloquence* (1901). See the chapter on Reed in H. B. Fuller's *Speakers of the House* (Boston, 1909).

REED, WALTER (1851-1902), American bacteriologist, was born in Gloucester county, Va., on Sept. 13, 1851, and was educated at the University of Virginia and Bellevue Medical school (M.D., 1879). In 1874 he entered the medical corps of the U.S. army as assistant surgeon, with rank of lieutenant. In 1893 he was promoted to surgeon, with the rank of major, and made professor of bacteriology in the newly-organized Army Medical school. In 1898, when the Spanish American War opened, he was appointed chairman of a committee to investigate the causation and mode of propagation of typhoid fever, an epidemic of which had broken out among the soldiers. His *Report on the Origin and Spread of Typhoid Fever in U.S. Military Camps* (1904) revealed a number of points concerning the disease not before known, and emphasized others which had been little appreciated. In 1897 he and an associate proved the theory of Sanarelli—that the bacillus *Icteroides* was the specific cause of yellow fever—erroneous. In 1899, when the disease was especially severe in Cuba, he was made chairman of a committee to investigate its cause and method of transmission. His observation of many cases led him to discount the then prevalent idea that the disease was transmitted by fomites in bedding, clothing, etc., of patients suffering from yellow fever, and to revive the discarded notion of Dr. Carlos Finlay that the yellow fever parasite was carried only by mosquitoes. Since the disease was not taken by animals there was no method of proof except by experiment upon human beings. By a thorough set of experiments, in which some of Reed's co-workers sacrificed their lives for the cause, he proved to a sceptical world that the yellow fever parasite was carried only by the mosquito *Culex fasciatus* and that its bite caused the disease only under certain conditions. Possessed of this knowledge, American sanitary engineers eradicated the yellow fever from Cuba, and it has since been largely eliminated from civilized portions of the world. Reed died at Washington, D.C., on Nov. 23, 1902.

See H. A. Kelly, *Walter Reed and Yellow Fever* (1906), which contains a bibliography of Reed's publications; also P. De Kruij, *Microbe Hunters*, pp. 321-333 (1916).

REED, a term applied to several distinct species of large, water-loving grasses. The common or water-reed, *Phragmites communis*, occurs along the margins of lakes, fens, marshes and placid streams, not only throughout Great Britain and the United

States, but widely distributed in Arctic and also in temperate regions, extending into the tropics. Another very important species is *Ammophila arenaria* (also known as *Panicum arenaria*), the sea-reed or marram-grass, a native of the sandy shores of Europe and north Africa. Both species have been of notable geological importance, the former binding the soil and so impeding denudation, and actually converting swamp into dry land, largely by the aid of its tall (5 to 10 ft.) close set stems. The latter species, of which the branching rootstocks may be traced 30 or even 40 ft., is of still greater importance in holding sand-dunes against the sea, and for this purpose has not only been long protected by law, but has been extensively planted on the coasts of Norfolk, Netherlands, Gascony, etc. Other reeds are *Calamagrostis* (various species), *Cyperium argenteum* (pampas grass), etc., also *Arundo donax*, the largest European grass (6 to 12 ft. high), which is abundant in Europe. Reeds have been used from the earliest times in thatching and in other branches of construction, and also for arrows, the pipes of musical instruments, etc. Reed pens are still used in the East. Plants belonging to other orders occasionally share the name, especially the bur-reed (*Spartanium*) and the reed-mace (*Zypha*), both belonging to the family Typhaceae. The bulrushes (*Scirpus*), belonging to the family Cyperaceae are also to be distinguished.

REEDBUCK, a foxy-red South African antelope (*Redunca arundineum*) of medium size, with a bushy tail, a bare gland-patch behind the ear, and in the male short horns which bend forwards in a regular curve. There are several other species of the genus *Redunca* to which the name of reedbuck is also applied, one of these ranging as far north as Abyssinia, and another inhabiting west Africa.

REED INSTRUMENTS, a class of wind instruments in the tubes of which sound-waves are generated by the vibrations of a reed mouthpiece. Reed instruments fall into two great classes: (1) those blown directly by the breath of the performer, who is thus able to control more or less the character of the expression; (2) those in which the wind supply is obtained by mechanical devices, such as the bag of bagpipe instruments or the bellows of such keyboard instruments as the organ and harmonium.

Directly-blown reed instruments comprise the section of modern wind instruments known as the "wood wind," with the exception of flute and piccolo; and they are classified according to the kind of reed vibrator of which the mouthpiece is composed. There are three kinds of reed mouthpieces: (1) the single or beating reed; (2) the double reed; (3) the free reed, all of which perform the function of sound-producer.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART
THE ANCIENT SYRX OR PIPE OF PAN, CONSISTING OF TUBES OF VARYING LENGTHS, BOUND TOGETHER

(For illustration see FREE REED VIBRATOR.) The reed used consists of a thin tongue or strip of reed, cane or some elastic material, thinned gradually to a delicate edge. It is adapted to the tube in such a manner that when it is at rest the opening at the mouthpiece end of the tube consists only of a very slight aperture or chink, which is periodically opened and closed by the pulsations of the reed when acted upon by the compressed breath of the player. This principle is common to all reed mouthpieces, and the difference in timbre is in a measure due to the manner in which the pulsations are brought about and the degree of elasticity permitted.

The single or beating reed consists of a single blade bevelled at the edge and placed over a table or frame communicating with the main bore of the instrument, against which it beats, causing a series of pulsations. The single reed is common to all the members of the clarinet family, consisting, besides the clarinet, of the basset-horn or tenor, and of the bass and pedal clarinets; of the batphone, an early bass clarinet, and of the saxophone. The ancient Greek aulos (q.v.) was also undoubtedly used with a beating

reed during some period of its history.

The *double reed* consists of two blades of reed or other suitable material tightly bound together by many turns of waxed silk, so that above the construction the tube formed by the two blades has an oval section, while below, where it communicates with the main bore of the instrument, it is strictly cylindrical. The chink in this case is thus formed by two thin walls of reed of equal elasticity (see *Oboe*, *Bassoon*). The double reed is common to the members of the oboe family, consisting, besides the oboe, of the cor anglais or tenor, of the fagotto or bassoon, and of the contra fagotto or double bassoon; and it is also used in the sarrusophone family, instruments of brass but classed with the wood wind on account of the mouthpiece and fingering.

The *free reed* is not represented among members of the modern wood wind, and, as adapted to a directly-blown instrument, only finds application in the Chinese cheng, the prototype of the harmonium, and in the mouth-organ or harmonica.

The reed in wind instruments produces a peculiar tone quality to which it has given its name; it varies in the three different kinds of mouthpieces without losing its fundamental reedy timbre.

For reed instruments of the second class, viz., those indirectly blown by mechanical means, see under the names of the individual instruments—*BAG-PIPE*; *CONCERTINA*; *HARMONIUM*; *ORGAN*; etc.

REEVE, a bailiff, steward or business agent; in early English history, one entrusted with administration of a division of a country; the chief magistrate of a town or district. The name survives in Canada for the president of a village or town council and in the United States, in composition, as port-reeve, town-reeve, etc.

REEVE, in ornithology, the female of the ruff (*q.v.*).

REEVES, JOHN SIMS (1818-1900), English vocalist, was born at Woolwich, Sept. 26, 1818, and received his musical education from his father, a musician in the Royal Artillery. He studied with Hobbs and T. Cooke, and appeared at Drury Lane (1841-43) in subordinate tenor parts. He studied under Bordogni in Paris and Mazzucato in Milan, and his *début* in Italian opera was made at Scala as Edgardo in *Lucia*. His career on the English operatic stage began at Drury Lane in Dec. 1847 in *Lucia*, under the conductorship of Hector Berlioz. At the Norwich Festival (1848) he made a great sensation in "The enemy said," from *Israel in Egypt*. He was recognized as the leading English tenor; and in Costa's *Eli* and *Naaman* the tenor parts were written for him. His first Handel Festival was that of 1857. He died at Worthing, Oct. 25, 1900.

REEVES, WILLIAM PEMBER (1857-1932), New Zealand administrator, was born at Canterbury, New Zealand, on Feb. 10, 1857, and educated at Christchurch, N.Z. He read for the law and was called to the New Zealand bar, but eventually took up journalism, becoming editor of the *Canterbury Times* and the *Lyttelton Times*. In 1887 he entered parliament, and held office from 1891 to 1896 as minister of education. He published several volumes on the history of New Zealand, and one volume of verse, and contributed to the 10th and to the present editions of the *Encyclopædia Britannica*.

RE-EXPORTS: see *EXPORTS*.

REFECTORY, the dining-hall of a monastery, convent, etc. There frequently was a sort of ambo, approached by steps, from which to read the *legenda sanctorum*, etc., during meals. The refectory was generally situated by the side of the south cloister, so as to be removed from the church but contiguous to the kitchen. The word is also sometimes applied to any large hall used for community meals, as in a college, school, etc.

REFEREE, a person to whom anything is referred; an arbitrator. The court of referees in England was a court to which the house of commons committed the decision of all questions as to the right of petitioners to be heard in opposition to private bills. The court now consists of the chairman of ways and means, the deputy chairman and not less than seven other members of the house appointed by the speaker, and its duty, as defined by a standing order, is to decide upon all petitions against private bills, or against provisional orders or provisional certificates, as to the rights of the petitioners to be heard upon such petitions. In the high court of justice, under the Judicature act 1873, cases may

be submitted to three official referees, for trial, enquiry and report, or assessment of damages. Enquiry and report may be directed in any case, trial only by consent of the parties, or in any matter requiring any prolonged examination of documents or accounts, or any investigation which cannot be tried in the ordinary way.

UNITED STATES.—The term referee is commonly applied to persons to whom a court sends a cause or some question therein for determination or for the purpose of taking evidence and reporting upon the same. In this connection it is synonymous with such terms as auditor, commissioner, arbitrator, assessor, etc. In some states the term is applied to a master, who is appointed in equity suits pursuant to statute as distinguished from masters appointed pursuant to the old equity practice. See *EQUITY*.

REFERENDUM AND INITIATIVE, two methods by which the wishes of the general body of electors in a constitutional state may be expressed with regard to proposed legislation. They exist in a variety of forms. The referendum may be obligatory or optional. Under the former type certain classes of actions by a legislature are required, ordinarily by constitutional provision, to be referred to a popular vote for approval or rejection. Amendments to constitutions proposed by legislatures are subject in most states of the United States, for example, to an obligatory referendum. Under the optional (or facultative) referendum a specified number of voters by petition may demand a popular vote on a law passed by a legislative body. By this means the actions of a legislature may be overruled. Certain classes of legislation usually are excepted from the optional referendum. The referendum may also be constitutional or legislative depending on the nature of the matter referred. In the United States questions subject to the obligatory referendum are mostly constitutional while those subject to the optional referendum are invariably legislative. The obligatory and optional forms are to be distinguished from the submission by legislative bodies of particular questions to a referendum or plebiscite, the effect of which may be determinative of the issue or only advisory to the legislature.

By the initiative a specified number of voters may invoke a popular vote on a proposed law or constitutional amendment. In its direct form a proposal supported by the requisite number of voters is submitted directly to a popular vote for decision. Under the indirect form the legislature has an opportunity to enact such a proposal. If rejected, the proposition is submitted to a popular vote, in some instances with an alternative proposal by the legislature or with a statement of its reasons for rejection.

The initiative and referendum came into common use in Switzerland in the Liberal reaction after the Paris revolution of 1836. In 1831 St. Gall first adopted the "facultative referendum" (then and for some time after called the "veto"), and its example was followed by several cantons before 1848. The "obligatory referendum" appears first in 1852 and 1854 respectively in the Valais and the Grisons, when the older system was reformed, but in its modern form it was first adopted in 1865 by the canton of rural Basle. The initiative was first adopted in 1845 by Vaud. In the case both of the facultative referendum and of the initiative each canton fixes the number of citizens who have a right to exercise this power. Both institutions have been used freely in both federal and cantonal matters. Swiss experience with the devices of direct legislation was influential in the adoption of the initiative and the optional referendum in U.S. states and municipalities.

BRITISH EMPIRE.—The Australian commonwealth constitution provides for neither the initiative nor the optional referendum, but the obligatory referendum exists with respect to amendments to the constitution proposed by parliament. Such use of the referendum by states with written constitutions is an action by the people in its constituent capacity with respect to the alteration of the fundamental law. It is different in theory from the initiative and the optional referendum which provide the people with a check, both positive and negative, on the representative assembly. The commonwealth parliament also may submit by special action specific issues to referendum. By this means in 1916, and again in 1917, the vital question of extension to service abroad of compulsory enlistment (which was already in use for

home defense) was referred to the electorate and on each occasion rejected.

New Zealand used the machinery of the referendum in 1911, 1914, 1919, 1922, 1925 and 1928 in order to discover the will of her people respecting the troublesome question of prohibition. On each occasion prohibition was rejected, and at the last referendum in Nov. 1928 a large majority voted against prohibition.

Canada.—The referendum in the legislative sense has, when resorted to, been as a rule the result of special laws, and particularly on the question of prohibition. The suppression of the liquor traffic was thus carried out in Alberta, 1915, Manitoba, British Columbia and Saskatchewan in 1916, and Ontario in 1919. In 1920, however, British Columbia by means of a referendum, reversed its decision and adopted a system of government liquor control—an example subsequently followed by Manitoba, Saskatchewan, Alberta and Ontario. Under United States influence the referendum has been widely introduced into local government matters, more particularly as regards the submission of by-laws about money to the people, and in this restricted sense has operated successfully, though upon occasions it has proved difficult to induce any large number of voters to exercise the franchise.

Irish Free State.—The Irish Free State constitution, 1922, requires a referendum to be taken on any measure passed by the Dail, if a demand is made by either one-fifth of the senate or one-twentieth of the electorate.

European Countries.—Formal adherence to democratic doctrines in drafting new constitutions in various European countries after World War I led to frequent provision for use of the initiative and referendum. These provisions were used but little, and by 1945 conquest and revolution had nullified most of these constitutions. The German Constitution of 1919 empowered the president to order a referendum on any law passed by the reichstag; he was also empowered to order a referendum on questions in dispute between the reichstag and the reichsrat. The optional referendum was allowed on petition of one-twentieth of the voters if one-third of the reichstag had requested the deferment of the publication of a law. One-tenth of the voters might initiate a proposed law. By this means in 1926 the electorate voted on the question of the confiscation of the property of the Hohenzollerns and other former ruling houses, and in 1929 on a proposal to renounce the war guilt clause of the Versailles Treaty and to make it criminal for an official to agree to make payments to a foreign power, a clause directed toward officials who had just signed the Young Plan. Both measures failed for lack of the requisite majority of all qualified voters.

The Estonian Constitution of 1920 provided for the optional referendum and the initiative. The legislative body was given an opportunity to adopt initiated measures before the popular vote. The constitution provided for a dissolution of the assembly if the people rejected a measure adopted by it or adopted an initiative which it had rejected. Constitutions of Lithuania, Latvia and Austria included provisions regarding direct legislation.

The United States.—The obligatory referendum on amendments to state constitutions proposed by state legislatures, first adopted by Connecticut in 1818, has become the prevailing method for the amendment of state constitutions. It was used in 1945 in all states except New Hampshire and Delaware. In some states a referendum is obligatory on bond issues and a like rule is widespread in local government for bond issues, tax questions, and related matters. Owing to the detailed nature of state constitutions and the necessity for their frequent amendment, many issues not of a nature to arouse great interest among the voters are referred to them for amendment.

In U.S. usage, "initiative and referendum" or "direct legislation" refers, not to the obligatory referendum, but to the optional referendum on legislation and to the initiation of laws or constitutional amendments by the voters (with the assumption that a popular vote or referendum on the initiated measure will follow). These devices were adopted in the U.S. under the leadership of groups hostile to machine rule, distrustful of legislatures and with a deep faith in democracy. The belief was that by granting the people a means to overrule legislative action and to

initiate popular votes on legislation, abuses at the time characteristic of state legislatures might be prevented. Conservative groups were hostile to the adoption of the institution of direct legislation. In the period 1898-1918, 18 states adopted operative systems for either the initiative or the referendum or both. The chief use of direct legislation has been in the western states, and it has not fulfilled the hopes of its advocates or the fears of its opponents. In practice the referendum is used by groups which consider themselves aggrieved by an action of the legislature and feel that they might persuade a majority of the electorate to support them in their demand that the law not go into effect. The initiative tends to be used by groups which have been unable to induce the legislature to enact a desired law. By the initiative they can seek direct action by the electorate.

In the period 1924-36, voters of the states passed on 1,493 measures, 1,021 of which were constitutional amendments submitted under the obligatory referendum. In 75 instances the optional referendum was used; 101 initiated constitutional amendments were voted upon as well as 147 initiated laws. The initiative and referendum are thus much less important than the obligatory referendum in bringing issues to the voters. Moreover, a large proportion of the instances of their use occurs in California and Oregon. In the legislative process as a whole the initiative and referendum are comparatively unimportant in so far as the volume of legislation directly affected is concerned. The devices may be regarded, in the words of Woodrow Wilson, as a "gun behind the door" to be used when abuses arise in the legislative body.

REFLECTION. When waves of any kind travelling in one medium arrive at another in which their velocity is different, part of their energy is, in general, turned back into the first medium. This is termed reflection. If the surface of separation is smooth, i.e., if the irregularities in it are small compared with the wave length of the incident disturbance, the reflection is regular; if the surface is rough each facet reflects the rays incident upon it in accordance with the laws of regular reflection (see LIGHT) and the reflection, as a whole is irregular or diffuse. Consider, for example, the reflection of light at smooth and ruffled water surfaces. From the ruffled surface rays enter the eye after reflection from suitably inclined facets distributed over a wide area on the surface and a diffuse band of light is seen, while from the smooth surface only those rays reflected at the requisite angle from a small area on the surface can reach the eye. In the first case the optical system of the eye focuses the water surface on the retina just as it does all other rough surfaces. In the latter the rays appear to come from a laterally inverted replica of the luminous source situated as far below the surface as the source itself is above, and it is this image which is then focussed on the retina. The diffusion of light by matt surfaces in general is an example of the same phenomenon differing only in the number and size of the facets which scatter the light.

Echoes and reverberations are caused by the reflection of sound (q.v.) and the "fading" of wireless signals (in part) by variations in the conditions under which the electromagnetic waves are reflected by the Heaviside layer in the upper atmosphere. (See WIRELESS TELEGRAPHY.)

REFLECTORS. The light from most illuminants is distributed in a manner such that under most conditions it cannot be efficiently employed without the use of reflectors, or other media for re-directing the light into useful angles. Reflectors in common usage today not only control the direction of the light, but also

serve to shield the eyes from the brilliancy of the bare light source, and diffuse the light to produce a comfortable illumination. While all materials have to some degree the qualities of reflection, only a few can be used efficiently as accessories for primary light sources. Consideration of permanence, transmission, opacity, character of surface and reflection factor are necessary in determining the fitness of materials for use as reflectors.

The materials ordinarily used for reflectors are classed as (1) translucent, in which a part of the incident light is reflected and part transmitted or absorbed, and (2) opaque, in which part of the light is reflected and the rest absorbed; both types are necessary depending upon the character of the light distribution. The three types of light distribution from reflectors used for general interior illumination are classed as (1) direct, (2) semi-indirect and (3) indirect, a classification based upon the percentage of emitted light below or above the horizontal plane through the centre of the light source. Direct reflectors shed more than half of the emitted light below the horizontal; semi-indirect reflectors throw more than half above the horizontal with a small amount below; and indirect reflectors throw all of the light upward to the ceiling which reflects it downward.

The shape of the candle-power distribution curve of a reflector is within the control of the designer because of the diverse types of reflection characteristics available. Where very accurate control of the light is necessary, polished-metal, mirrored-glass, or prismatic-glass surfaces are usually employed. These media have a reflection characteristic similar to a mirror where the angle of reflection is equal to the angle of incidence. Automobile headlight reflectors, searchlight and floodlight projectors, and industrial high mounted luminaires are typical of the equipment requiring this type of reflector. An inconsiderable corrugation of surface of this type produces a slight diffusion of the light and yet permits of a very accurate control of the light distribution. Dull-finished metal surfaces, of which unpolished aluminium is typical, have some of the light-directing characteristics of the polished surface but more diffusion. This type of surface is commonly used for small local lighting reflectors and in some types of floodlights and spotlights. The inherent low cost, ease of manufacture and light weight make spun aluminium popular for many uses.

Rough or mat-finish reflecting surfaces permit of little or no actual control of light, since a beam of light striking a mat-finish surface will be reflected in all directions. Black magnesium carbonate is typical of several surfaces falling in the classification, although it lacks the necessary permanence, soils easily, and is difficult to clean. Porcelain enamelled metal combines the diffusing characteristics of mat-finish surfaces with some of the light control characteristics of glass surfaces. Porcelain-enamelled reflectors are popular for industrial lighting purposes because of the ease of cleaning them when they get dirty. The cost is low because the metal shell can be formed by spinning, or in the press, and the porcelain enamel finish put on afterwards. Opal glass has the same general reflection characteristics as porcelain enamel and also transmits some light—a feature desirable for some locations. (See ILLUMINATING ENGINEERING; TELESCOPE; MIRROR; MICROSCOPE; LIGHT.) (J. M. K.)

REFORMATION. This word, like "Catholic," is in itself a question-begging term; but both are adopted, if only under protest, in the general speech of the present day. By "Reformation," then, we mean that religious revolution of the 16th century which has divided western Christendom into two camps, the Catholic and the Protestant. This was in itself a very complex movement, due to a multiplicity of causes which may be grouped under four main headings: *moral, doctrinal, economic and political.*

Moral Causes.—These were the most important of all, for they lay at the very root. From St. Bernard at the beginning of the 12th century to Bishop Fox, who founded Corpus Christi college at Oxford in 1516, there is no generation from which we cannot choose orthodox and distinguished churchmen who urged the crying need for Church reform in language which might seem harsh from the pen of a modern Protestant. From Innocent III. in 1215 to Leo X. in 1512, nine great world-councils were held, with Church reform in the forefront of their programme; yet

each in turn confessed the failure of its predecessors, and the Council of Trent (1545) testified to the impotence of them all.

The attempt to saddle the Black Death (1348-50) with this state of things is grossly unhistorical. Two of the greatest cardinals of the 13th century, St. Bonaventura (d. 1274) and Hugues de St. Cher (d. 1260) were among the most outspoken of all our witnesses against the clerical morals of their day. Even plainest is the testimony of another very distinguished bishop, Guillaume Durand, who was consulted for the Council of Vienne (1311). In his long memorial, he drew a terrible picture of the reigning and growing abuses, and concluded that the thing most needful was "a reformation in head and in members," that is, from the pope and his court downwards; and this became a watchword not only at succeeding councils, not only among outside critics, but sometimes of popes. It is acknowledged on all hands that the abuses emphasized at the council of 1215 were in many respects even more rampant in 1512, and that the discipline so often demanded was never realized until after the Council of Trent had completed its long work (1564).

The celibacy of the clergy had presented great and continual difficulties. (See CELIBACY.) Even so energetic a reformer as St. Anselm was practically compelled to abandon his design of separating the English clergy from their partners. A visitation of the diocese of Hereford in 1397 shows 52 concubinary clergy known to the bishop out of 281 parishes. Another of Lausanne diocese in 1416-17 shows, among 273 communities, more than 80 clergy known as concubinary. The Oxford chancellor Gascoigne (1450), a strong anti-Lollard, tells us that the bishop of St. Asaph of his day was earning 400 marks (the equivalent of something like £5,000 a year in modern money) from the licences for concubinage that he sold to his priests; and, though these figures are doubtless greatly exaggerated, yet Sir Thomas More does not deny that there was something of the same system in Ireland; and similar evidence comes to us from other parts of Europe.

It is rare to find any mediaeval author who, if he generalizes about monks, friars and nuns at all, fails to complain of the immoral example which they too frequently set. St. Bernardino of Siena (d. 1444) tells us that "very many" men of his day had no belief in Heaven, and looked upon the Christian scriptures as merely interesting fictions, because of the evil lives of cloisterers and other clergy. Pope Gregory X. had said the same at the council of Lyons (1274), and by about 1500 it had become a commonplace that the lives of the clergy were mainly responsible for the increase of heresy. And some of the most distinguished mediaeval witnesses, such as Cardinal Hugues de St. Cher (d. 1260) and St. Catharine of Siena (d. 1380) point out that clerical vices were naturally reflected and even exaggerated in the laity. Again, long before Luther's appearance, orthodox Catholics were emphasizing the abusive side of many Church ceremonies and practices; the sale of indulgences (*q.v.*), the multiplication of holy-days and the vice and riot which often marked these festivals; the abuse of the mass and of the consecrated oils for witchcraft; and the extent to which clerical immunities encouraged crimes. The laity of the later middle ages, with all their faults, were improving far more rapidly than the clergy; and this gave a proportionately increasing impetus to criticism.

Doctrine.—Here the clergy had once been supreme, and would probably have had little difficulty in maintaining their authority if they had kept unquestionable moral superiority. Few people are really interested in pushing theological enquiries very far, and so long as men's conduct corresponds to their doctrine, the vast majority of mankind are willing to accept this at least as a working theory, and are under no temptation to question the speculative basis of practices which they approve. So long as there was no deep gulf between what the clergy actually were and what the people had a right to expect of them, free-thought was mainly limited to a few philosophers here and there, to a few weavers at their loom or cobblers at their bench, and to that dead weight of indifference, of resistance against idealism of any kind, which

¹More than 200 orthodox witnesses are cited on pp 379-419 of G. G. Coulton's *Five Centuries of Religion*, Vol. II.

has prevailed in every generation among the masses who need to concentrate so much of their thoughts and their labour upon the elementary problems of daily bread. We have abundant proof that the majority of the mediaeval population were not actively religious; but for a long time the enthusiastic churchman had generally nothing worse to struggle with than inertia and complacent ignorance. About the year A.D. 1000, there came a revival comparable almost to that which we call the Renaissance. With this revival we also find signs of free-thought and religious friction; an ice-bound world was now thawing; therefore it moved less regularly and under less strict control than might have been desired. Many features of the then existing dogmatic scheme had been created less by profound philosophy than by popular feeling or by comparatively unreflecting impulses. All men, for instance, had gradually grown to assume that we must take that text "many are called, but few are chosen" in its most baldly literal sense. Even in the 13th century, and in a philosopher so remarkable for balance and moderation as St. Thomas Aquinas, we find that the "few" who shall be saved are directly contrasted with the "very many" who shall go to hell. His contemporary, the Franciscan Berthold of Regensburg, whom Roger Bacon singles out as the greatest preacher of the day, actually commits himself in one passage to a rough numerical calculation; only about one in 100,000 shall be saved; and few mediaeval theologians put it more favourably than one in 1,000.

Moreover, they exerted all their imagination and their rhetoric to impress upon their hearers the terrible significance of this separation between the sheep and the goats. All was to depend upon the last moment of life; and, even there, it must depend mainly upon the faith in which the sinner died. Berthold asks his hearers to imagine themselves writhing white-hot within a white-hot universe until the day of judgment, when the pains will be greatly increased. Let them imagine this continuing for as many years as all the hairs that have grown upon all the beasts in this world since the creation; and, even then, the sinner will be only at the beginning of his torments. Yet Berthold was one of the kindest of men; if he defended the current dogma with this ferociously implacable logic, it was because he had inherited it as part of the deposit of faith, and because he now found himself faced by an opposition which no student of the Reformation can afford to ignore.

Heresy.—The first half of the 13th century had witnessed the rise of several powerful heretical sects, which even the eloquence and influence of men like St. Bernard could not extinguish, though the leaders could be taken and slain. All these sects were more or less antisacerdotal; and more than one held among its chief tenets that the personal unworthiness of the priest impairs or destroys the value of the sacrament which he administers, a doctrine to which some colour had been lent by the very methods taken to combat clerical concubinage by the great pope Gregory VII. (d. 1085).

Towards the end of the century, these popular and comparatively unlearned revolts were succeeded by others of very different intellectual weight. The Waldensians [1175] took their stand upon the Bible; this they read in the vernacular, and committed to memory with a diligence which, as even their persecutors complained, ought to have shamed the orthodox out of their ignorance.

About the same time, the complete works of Aristotle began to filter into the University of Paris through translations from the Arabic, and, a little later, through more accurate versions made by orthodox scholars. The Bible led the Waldensians to deny any essential distinction between clergy and laity; but they long persisted in regarding themselves as orthodox Catholics. The new Aristotle, and especially his Arabic translators and commentators, led a certain number of Paris teachers to adopt the teaching of Averroes (q.v.), and thus to deny such fundamental doctrines as the personality of God, the creation, and the immortality of the soul.

But stern measures of repression, first by bishops and clergy and then by the Inquisition (q.v.), prevented the general diffusion of these doctrines. In southern France, indeed, about 1200, it was complained that the heretics outnumbered the

Catholics; but Innocent III. exterminated them in a merciless crusade; and the new orders of friars, instituted soon afterwards, did almost as much as the sword and the Inquisition to crush movements which were necessarily sporadic and disorganized, since there was no chance of bringing that side of university scholarship into quiet and steady co-operation with the less articulate impulses of the multitudes. Moreover, from the very first, there was naturally a good deal of base leaven in these revolts; and even the Waldensians, whose original tenets resembled modern Quakerism in a good many respects, were gradually compelled, under persecution, to make common cause with other rebels whom they had begun by opposing.

Orthodoxy.—Society as a mass was not ripe for revolution; the nonconformists had too little of a positive programme to substitute for that of the conformists. For the orthodox had gradually set themselves to systematize the theology which they had inherited. Peter Lombard, bishop of Paris (d. 1164) compiled his *Sentences*, i.e., texts from the Bible and from the fathers, arranged with comments so as to present a fairly consistent foundation upon which most of later mediaeval theology was built. St. Thomas Aquinas (d. 1274) built up a powerful constructive plea for Christianity in his *Summa contra Gentiles* and a wonderfully complete synthesis of Christian tradition with Aristotelian philosophy in his *Summa totius Theologie*.

From the mid 13th century onwards, there was a tendency in official circles to look upon the intellectual and social equilibrium as complete; philosophers were less concerned to advance than to hold the positions already gained and to strengthen the outworks from generation to generation. Roger Bacon, the slightly older contemporary of Aquinas, might indeed criticize this imposing philosophical structure in terms which almost anticipate Huxley; it rested (he said) upon a Bible misunderstood, and an Aristotle misunderstood, and upon an almost total neglect of the physical and mathematical sciences. But Bacon exaggerates so far as Aristotle is concerned; and he, like those few who thought with him, had no chance in face of the Inquisition; therefore, though a great deal of Averroism survived at the universities, and we have evidence throughout the later middle ages for groups of "intellectuals" who treated Christianity as an outworn superstition, it was improbable that these men would ever have led a revolt. The academic tendency was rather to evade serious issues under shelter of the theory of "double truth"; things (they said) might be theologically true even while they were philosophically false. Far more important was the gradual change of thought among the masses. These, as zealous teachers complained, had always looked too grossly for tangible and immediate results. Saints' images which refused to work expected miracles might be scorned or maltreated; the failure of St. Louis' crusade led common folk to say "nowadays, Mohammed is stronger than Christ." The Black Death inflicted a terrible shock, from which all vital things recovered rapidly, but which shook all mere conventions to their base; to that extent, it must certainly be counted among the hastening factors of the Reformation.

The popes, by their voluntary desertion of Rome for Avignon, did much to impair their prestige, especially in England, where they seemed necessarily partisans of France in the Hundred Years' War. This was expressed in popular rhymes: "The pope is a Frenchman now, but Jesus is English; let us see who will do most, Jesus or the pope!" Then came the Great Schism, with 39 years of struggle between rival popes upon whose claims, though historians are mostly in agreement, the Roman church has never pronounced so clearly and unequivocally as to render it a question settled for all time. Among contemporaries, St. Catharine of Siena was certain that Urban was true pope, and Clement a pretender. But the Spaniard, St. Vincent Ferrer, proves with every reinforcement of scholastic logic, not only that Clement is true pope, but that no man who, having heard the pleas in his favour, decides for Urban, can hope for heaven. The effect of this upon the masses can scarcely be exaggerated; it was the schism, perhaps, which lent its greatest force to the heresy of Wycliffe. For, at the same time, popular devotions and a popular theology were growing up under the wing of the Church,

yet in considerable independence of the priesthood.

Piers Plowman is only one of many books which show how pious and thoughtful folk, outside the hierarchy, were exercised by such problems as predestination, or the damnation of virtuous non-Christians, or the papal doctrine of indulgences (*q.v.*). The multiplication of books of popular piety in the last generations before the Reformation is enormous. For good or for evil, the people were beginning to outgrow clerical tutelage. Even in the foundation of schools and hospitals, the laity were beginning not only to pay their money, as they had done for long past, but to demand control of their own foundations. There was new life everywhere about 1500; but the gains were far more secular than sacerdotal.

Economic Causes.—During the later centuries of the middle ages, clerical possessions were enormous; churchmen owned a proportion which has been variously estimated at one-fifth or one-third of the whole landed property; yet they claimed to be free of taxation by the state. This naturally led to extreme friction; the preamble of Boniface VIII.'s celebrated bull *Clericis Laicos* (1296), in which he strongly asserted this claim for immunity, runs: "That the laity are bitterly hostile to the clergy is a matter of ancient tradition which is also plainly confirmed by the experience of modern times."

Equal friction arose from the farther claim, which had gradually grown up and was finally fixed by John XXII. (1316-34), that all Church benefices belong to the pope, who may appoint whom he will. This naturally led to a systematic trade in benefices at the Roman court: "Nothing is to be had at Rome without money," wrote Aeneas Silvius, the future pope Pius II. (1458-64). The popes took from each bishop half of his year's income (annates), and proportionately from abbots of great monasteries. Justice was sold in all the Church courts even more frequently than by secular judges; from at least the 12th century onwards, it was notorious that the archdeacons derived a large proportion of their income from bribes. These economic causes for reformation are most pitifully summed up in the *Hundred Grievances of the German Nation*, laid before Adrian VI. (1522-23) by the German princes.

The Inquisition.—Moreover, the Inquisition itself, by its very constitution, had become a terrible economic burden. It had always paid its way by wholesale confiscations; even "reconciled" heretics must lose their goods. Therefore when heresy had been brought under control, the Inquisition lost its chief reason for being. In the 15th century, when the Inquisition was first established, the papal treasury was empty, and the popes were forced to raise an interest in the Inquisition which was not to be found in the 16th century.

In the 16th century, the Inquisition directed much of its energies to the suppression of witchcraft; for an enormous number of its chief customs still survived, especially among the peasantry, who form the overwhelming majority of the population. Many peasants, said Berthold of Regensburg (1250), and especially many peasant women, cannot take any step in life without having recourse to witchcraft. Therefore, easy though it was to raise an outcry against some unpopular individual, any general enforcement of severe measures against witchcraft must have been extremely unpopular. The enormous multiplication of witch-hunts during the 15th century—for on this side Joan of Arc's fate is quite typical—was both symptom and cause of a deep gulf between the ignorant multitude and the theology of leaders like Aquinas. "Every Inquisitor whom [the Church] commissioned to suppress witchcraft was an active missionary who scattered the seeds of the belief ever more widely" (Lea). A bull of Innocent VIII. in 1484 had the practical effect that thenceforward to question the reality of witchcraft was to question the utterance of the vicar of Christ, "Thus the Inquisition in its decrepitude had a temporary resumption of activity" (Lea). Here again, however, we are to some extent anticipating; for the Inquisition was not only an economic but also a political force.

But, before quitting the economic factors, we must remember that they brought as much weakness as strength into the Reformation movement. It is evident that an economically irreproachable

Church would have been as impregnable as the earliest Christian society had been; but it is equally true that the purity of reform was very early tainted by greed; so that, when force was used on both sides, there was little or no moral difference between a defensive commercialized hierarchy and an aggressive squirearchy eager for plunder.

Political Causes.—The political factor, though by itself it might never have led to actual revolt, came in at the last stage with decisive effect. It was the struggle with Protestantism which evolved the half-way principle of *cuius regio, eius religio*; "the ruler's choice determines the established religion of his territory"; and this in turn has led to our modern toleration of all creeds. But the mediaeval ideal had been one empire with one religion; and the actual conditions cannot be better described than in the words of the jurist-historian F. W. Maitland (*Canon Law in the Ch. of England*, p. 100), "We could frame no acceptable definition of a State which would not comprehend the [mediaeval] Church. What has it not that a State should have? It has laws, law-givers, law-courts, lawyers. It uses physical force to compel men to obey the laws. It keeps prisons. In the 13th century, though with squeamish phrases, it pronounced sentence of death. It is no voluntary society; if people are not born into it they are baptized into it when they cannot help themselves. If they attempt to leave they are guilty of *crimen laesae maiestatis*, and are likely to be burned. It is supported by involuntary contributions, by tithe and by tax. And, it may be added, it claims to override, all the world over, the power of the secular State."

Much of this power came to the Church by a process as legitimate as that which could be claimed by most of the civil governments. The Church had consciously modelled her organization on that of the Roman empire; and she survived when the empire went to wreck. At first there was no question of serious rivalry with the earthly state. Gregory I., in face of an imperial edict or law which he might have been excused for interpreting as a trespass upon Church privileges, had no doubt about his duty of publishing the edict as he was commanded, even while he protested against it; "What am I," he wrote to the imperial council, "but dust and a worm? . . . a man set under authority."

It was only by degrees, and not without many reactions, even under Charles's weak successors, that the popes reached a position which rendered possible the claims of Gregory VII., a man of commanding genius and rare courage. Starting from Augustine's theory of the City of God, founded by Christ, in its contrast with the earthly city, founded by Cain, Gregory insists that the papal power of binding and loosing places him above all earthly sovereigns. It enables him to annul all oaths made contrary to God's will (of which the pope is interpreter) and to absolve all subjects from allegiance to an emperor whom the pope has deposed. Innocent III. (d. 1216) reasserted these claims both in theory and in practice; and at the death of the Emperor Frederick II. in 1250 the long struggle between papacy and empire was virtually decided in favour of the former.

National Spirit.—Yet the papacy now found a more formidable rival in the growing spirit of nationalism, which, no less than imperialism, must necessarily find itself in conflict with a non-national authority claiming moral dictatorship, and therefore political dominion, over the whole western world. It has sometimes been asserted that nationalism was unknown to the middle ages; that the one Church, with one Latin tongue for all educated Europe, effaced merely national divisions. This, however, is a very superficial view. In proportion as the heterogeneous mediaeval populations consolidated into nations, they developed also the consciousness of nationality; divisions became fewer than in the dark ages, but deeper; we may say that the papacy and the Latin tongue had scarcely more to do with the ending of the Hundred Years' War than with its outbreak; and Marsilius of Padua (1324) was on unassailable historical ground when he asserted that popes had very frequently been the authors of European wars.

France was the greatest nation in the 14th century; therefore she was nationally one of the most self-conscious; and it is she who came into directest conflict with the papacy. Boniface VIII.

(d. 1302) attempted to forbid taxation of the clergy by the State; again, he claimed that "all law is enclosed in the basket of the pope's breast." In his bull *Unam Sanctam*, he proclaimed to the world: "We declare that all human beings are subject to the pontiff of Rome; and we assert, define and pronounce this tenet to be essential and necessary to salvation." This attitude led to a conflict with Philippe-le-Bel of France, in which Boniface was humbled; this, again was a prelude to the transference from Rome to Avignon, where the popes in fact, though not in pretension, became virtually subjects of the French king. Even in England, where it might be argued that the clergy themselves were becoming more papalist than ever, and where Archbishop Arundel could proclaim that it was heresy to dispute any papal decretal (1408), yet king and parliament were putting very definite limits to papal control by their Statutes of Provisors and of Praemunire. Other sovereigns presently protected themselves by similar measures.

Publicists.—For, meanwhile, in the first half of the 14th century, publicists like Marsilius of Padua and William of Ockham (see OCCAM) enunciated theories which probably represented what a good many thinkers had long since been saying confidentially to each other in universities like Paris, and in great self-governing cities like Padua. For Marsilius and Ockham, the Bible is the great rule of life for Christendom; the supreme power resides in a council of the whole Church, to which Ockham, apparently, was ready to admit women, and which may judge the pope. Indeed, Ockham is ready to conceive a Christendom without the pope; true, there are certain functions which it would be difficult to arrange otherwise, but the papacy is not essential to the Church of Christ. These speculations formed a fitting prelude to the conciliar epoch (1414-57) during which, mainly at Constance (q.v.) and Basel, the Church attempted to put definite constitutional limits to papal autocracy. Both councils decreed, and compelled popes practically to admit, that a general council may judge and depose even a supreme pontiff, and that the pope cannot legislate without conciliar approval.

It is true that the constitutionalists here, as in the England of 1642, over-reached themselves, and the later mediaeval papacy profited by a reaction which rendered it despotic again within the Church. But the laity never forgot; and temporal princes grew more and more accustomed to maintain their own interests in open conflict with the pope.

Two factors contributed further to this political independence. The monastic reforms decreed by the councils of Constance and Basel, in so far as they were carried out at all, owed much of their success to the secular authorities; in this field, at any rate, it became increasingly plain that the Church was not likely to reform herself merely from within. Again, the later mediaeval popes were predominantly politicians. The papacy had become an Italian principate; the pontiffs constantly involved themselves in those civil wars which made Italy a "hostelry of pain" (Dante); and they showed no less selfishness and duplicity than the princes with whom they were contending. They were ready to go any lengths to secure a little more authority or a few more square miles of territory; as when Clement V. (1309) decreed that the resisting Venetians should be sold into slavery, and Gregory XI. and Sixtus IV. decreed the same for the Florentines and Julius II. for both Florence and Bologna. The bull by which Nicholas V. (1442) encouraged Portugal to what became the organized trade in negro slaves did not immediately show these disastrous results; but when, in 1538, Paul III. decreed slavery against all Englishmen who should dare to support Henry VIII. against the pope, nobody was deceived as to the selfishness of this political move. (For evidence on these points see articles SLAVERY and INQUISITION; also T. Brecht, *Kirche und Sklaverei*, p. 156.) A quarrel with this spiritual autocrat, however moral or religious might be the original cause of difference, became *ipso facto* a political quarrel. Therefore, in 1500, any spark might have kindled a general conflagration.

Martin Luther.—This spark, when it came, was in fact moral and religious; but it at once kindled the mass of inflammable politico-economic material. The pope was working his indulgences to an excess which strained loyalty to the breaking-point. Ber-

thold of Regensburg, long ago [1250], had complained that "many thousands" went to hell because they thought themselves to have bought absolution from these "penny-preachers." Gascoigne, the great Oxford chancellor [1450], wrote even more strongly, in proportion to the growing evil: "Sinners say nowadays 'I care not how many or what evils I do in God's sight; for I can easily and quickly get plenary remission of all guilt and penalty by an absolution and indulgence granted me by the pope, whose written grant I have bought for 4d or 6d, or have won as a stake for a game of tennis.'" (*Lib. Verdum*, p. 86; full translation in G. G. Coulton, *Social Life in Britain*, p. 204.)

Then, in 1517, the rupture came. A scandalous archbishop of Mainz promised Leo X. 10,000 ducats as a bribe for permission to hold three archbishoprics at the same time. This money was to be paid in part from the sums which here, as everywhere else, were being raised by the sale of indulgences for the building of St. Peter's at Rome. An Augustinian friar and university professor of Wittenberg, Martin Luther, expressed the general indignation by drafting 95 theses on the indulgence system, on which he challenged dispute with all comers.

We may say "the general indignation," for Germany was thoroughly prepared for this revolt. She had many flourishing cities, and a high general level of education for that time; the printing press had long been active; several editions of the vernacular Bible had been published, and very many little books of popular piety. The Greek and Latin classics were being studied busily, and in a far less pagan spirit than in Italy. The Inquisition, again, was comparatively inoperative in Germany; there was little chance of its nipping any doctrine in the bud before it had time to gain popular support. And, lastly, the weakness of the central Government was favourable to Luther; it was the patronage of a few local princes that sheltered his movement in its first stages.

GERMANY

The political complications were here very great; the empire contained more than 300 separate states, small and great, which often rendered little more than nominal obedience to the emperor. Luther was first summoned to Rome and then commanded to present himself before the papal legate at Augsburg (Oct. 1518). Finding that the legate practically demanded submission without discussion, Luther published his account of the interview as an appeal to the German people (*Acta Augustana*). Leo X. then sent an envoy, Miltitz, who was so tactful that a reconciliation might conceivably have been effected but for the Leipzig disputation on the papal primacy and supremacy (June 1519), to which Luther was challenged by the Dominican friar Johann Eck. Luther, in his months of preparation for this debate, discovered how many forgeries there were among the documents which seemed to tell most against him; and Eck, by driving him to the admission that not all the tenets of the Hussite heretics were wrong, widened the breach still farther. The younger university teachers were now on Luther's side; and, encouraged by the growing approbation of all classes among the laity, he began to appeal unhesitatingly and unceasingly through the pulpit and the press.

In three great treatises (1520) he took up a position from which he never after retreated on any essential point. For he had a positive programme; a national Church, free from papal interference; inspection of monasteries; limitation of holy-days and pilgrimages, and marriage for the priesthood as the best remedy for the standing disgrace of concubinage.

Leo X. met this programme with a bull (*Exsurge Domine*, June 1520) in which he condemned 41 propositions attributed to Luther. One of these is all the more significant because the condemnation was repeated in other papal letters: Luther had said "I do not wish the will of the Holy Spirit and the Church to be hindered." The pope, on the other hand, had said "I do not wish the Church to be hindered by the will of any man." The bull was sent to all the universities of the empire, and to the archbishops of the empire, and to the bishops of the empire, and to the cardinals of the empire, and to the pope himself. The bull was ordered to be read in all the churches of the empire. The bull was ordered to be read in all the churches of the empire. The bull was ordered to be read in all the churches of the empire.

Luther received encouragement from many quarters.

He was now excommunicate, and his writings were solemnly burned; he retaliated by burning the papal decretals with equal publicity. Luther had great virtues and great faults; but at this crisis even his faults had a value for the world; for his courage and self-assertion precipitated the crystallization of a thousand thoughts and impulses with which society had gradually become saturated, but which had remained in solution until now.

This Church quarrel now became the most burning question in all German politics. The young Emperor Charles V. was crowned in Oct. 1520, and fixed January for his first Diet, at Worms. He had followed the fight, and was determined to uphold the traditions of his ancestors. The princes insisted that Luther should not be placed under the ban of the empire without being heard in his defence; he was therefore summoned under a safe conduct. He decided to go, "even though there were as many devils at Worms as tiles on the house-roofs." Nearly 2,000 people came out from the city to welcome him. He was brought before the Diet (April 17) and asked whether he would retract his books and their contents; he requested a day to consider his answer. His reply on the 18th was clear and decided: "The duty that I owe to my Germany will not allow me to recant." Pressed still farther: "It is impossible for me to recant unless I am proved to be in the wrong by the testimony of Scripture or by evident reasoning." Pressed farther again, while the torches began burning down their sockets, as to the infallibility of general councils (the infallibility of the pope was not yet a necessary article of faith) he replied that these had sometimes erred by contradicting Holy Scripture, and he could prove it. At this, the emperor made a sign to break up the meeting.

The Credo of Charles.—Next day Charles read to the diet his own profession of faith; he stressed the authority not of popes but of councils; and upon that he was firm; here is a single friar now setting up his private judgment against 1,000 years of Catholicism, and "I have therefore resolved to stake upon this cause all my kingdoms and lordships, my friends, my body and my blood, my life and my soul." He called upon the diet to help him in this crusade; but "many turned paler than death." For the antagonism was here clearly stated; Luther was ready to stake all upon his own personal convictions, and the emperor upon his own loyalty to tradition. Here, then, was the clear parting of the ways. Both sides relied, fundamentally, upon the Bible. St. Thomas Aquinas had been as convinced as any later Protestant theologian that the Bible was inerrant not only in its spiritual teaching but even on matters of historical fact.

Authority and Judgment.—The real question which had gradually grown up during the Christian centuries, and which had now come to a point, was not as to the infallibility of the Bible but as to the methods of interpretation: was the book sufficient in itself, with no light beyond God's grace and the earnest searcher's conscience, or could it be rightly interpreted only in the light of ancient tradition, and by certain divinely-constituted teachers who, whenever they met in solemn convocation, were inerrant? Luther, in asserting that general councils had sometimes contradicted the Bible, had thrown down the gauntlet; at that point the emperor had naturally dissolved the assembly but only to take up the gauntlet solemnly next day; if the princes then turned pale, it was because they saw war imminent, and knew neither where it would end nor even (in most cases) on which side they must range themselves. To many, it seemed impossible to accept the existing constitution of Church and society as sacrosanct, to the extent of condemning all radical reform as sacrilegious, and all radical reformers as faggots for the stake.

Yet, on the other hand, they saw how intimately this treatment of nonconformity as heresy, this distrust of free discussion, and these methods of physical coercion, had grown into the whole social fabric, and therefore how great was the fear lest the edifice should collapse if once a friar were allowed to publish his own biblical interpretations against those of the councils, and to persuade the community that the burning of heretics is against the will of the Holy Spirit. Therefore, in the struggle that now follows, all other questions, however important in themselves, are

subordinate to this one fundamental antithesis between authority and private judgment. Did the princes desire a world in which the deposit of faith might safely be entrusted to the reason and religious feeling and good sense of the majority, or must physical force be held over men's heads everywhere and always as a menace, and be very frequently employed in fact? Were most men so firmly assured of the fundamentals that all contrary pleas of a small minority might be mainly left to work out their own confusion (as in More's *Utopia*) or was orthodox assurance so wavering that the centre of gravity might shift under the shock of a friar's contradictions, and the Church might turn upside down, and the State with it? The risk was plainly enormous; here was Luther, willing to take that risk for himself and for the world; but few of the politicians could have faced the crisis without serious misgivings.

The Wartburg.—No compromise between Luther and the emperor was now possible; on the 26th, it was announced that his safe-conduct would expire in 21 days. He left Worms; but he was seized by the advice and with the connivance of the elector of Saxony, and carried off to the elector's castle of the Wartburg near Eisenach. The emperor signed Luther's condemnation as a pestilent heretic (May 26); but his secretary wrote to a friend in Spain: "I am persuaded this is not the end, but the beginning. . . . Since [the Emperor's] edict, Luther's books are sold with impunity at every step and corner of the streets and market places."

Luther spent nearly ten months in hiding at the castle of the Wartburg, his "Patmos," as he afterwards called it. Here his pen was unceasingly busy with controversial pamphlets and his translation of the New Testament. But his body suffered from want of exercise, and his mind from natural doubts; could so many past generations and so many estimable contemporaries have been wrong, while he, the mere friar, was right as against them all? Might he not be dragging thousands down to hell with himself? Yet his convictions constantly returned more strongly than ever; and, by a natural reaction, he felt increasing confidence in his divine commission; to doubt of this, or to remain treacherously silent, would be to incur damnation. The gulf between authority and private judgment was thenceforward too wide to be bridged; and Luther emerged from the Wartburg as a determined revolutionary. Yet he was a conservative revolutionary; and this it was which brought him out of his retirement.

His doctrines had been spreading widely; the statistics of the German press are most eloquent here; in 1517 only 37 vernacular books were printed; in 1518 there were 71, and by 1523 the number had risen to 498, of which 180 were by Luther himself. For here was a population which, far beyond all others in Europe, had already been gaining a certain familiarity with the Bible in the vernacular. Fourteen editions in High German, and four in Low German, had appeared before 1518; and, though these editions were doubtless limited and therefore expensive, yet they must have done something to permeate popular thought. Most of the great cities were becoming Lutheran; the new doctrines spread, busily, rally enough, in Luther's own religious order (the Austin Friars) and in his University of Wittenberg.

Here, in fact, things went too fast. One of the Wittenberg professors, Andrew Bodenstein (Carlstadt), pushed matters to extremes; he lectured and preached and wrote against almost all the traditional ceremonies.

Momentum.—At the same time, and only 60 miles away, the populous weaving centre of Zwickau was in still greater religious commotion; three of the Zwickau enthusiasts came to Wittenberg, and Carlstadt persuaded the magistrates to publish an epoch-making ordinance, which practically transferred the whole direction of Church affairs to the laity, who at the same time undertook the poor relief and the moral discipline of the city. Carlstadt went even farther, and started an iconoclastic crusade. Luther's friend and colleague Melancthon (*g.v.*) disapproved strongly, but could do nothing. The elector also was seriously troubled; other princes were taking the Wittenberg disturbances as a text for armed intervention; and Luther risked his own personal safety to return and restore order. He preached at Wittenberg on eight

successive days: "I will preach reform, I will talk about it, I will write about it, but I will not use force or compulsion with any one. . . . The word will drop into one heart to-day, and to-morrow into another, and so will work that each will forsake the mass."

A new pope came to the throne in 1522, Adrian VI., a pious man sincerely anxious for reform. At the diet of the empire held at Nuremberg (1522-3) his nuncio pressed that serious measures should be taken against Luther, since Charles V.'s decree, however decisively worded, was practically a dead letter. The members of the diet answered by presenting a list of 100 grievances against the Church; the nuncio reported to the pope that "among a thousand men scarcely one could be found untainted by Lutheran teaching." Then Adrian died suddenly, and was succeeded by Clement VII., a Medici by birth and by nature interested less in reform than in papal prestige. His legate, Campeggio, though a most dexterous diplomatist, could effect very little. The Diet of Speyer (1524) began to plan a Church council for Germany, which would have separated from Rome and anticipated England in the formation of a national Church.

The Peasants' War.—It is from this moment that we must date "the beginning of the separation of Germany into two opposite camps of Protestant and Roman Catholic, although the real parting of the ways actually occurred after the Peasants' War" (T. M. Lindsay). That war, though precipitated by the Lutheran revolt, was essentially a mere continuation of the struggles described above. Luther's message was democratic; his language displayed the defects of his qualities; his extraordinary force and directness constantly tempted him into exaggeration, and added fuel to the social discontent which had smoldered for generations side by side with anti-clericalism.

Seven years after Luther's attack on the indulgence system, the peasants' revolt broke suddenly out (June 1524). It began on the upper Rhine, encouraged doubtless by the successful assertion of freedom by the Swiss. In a few weeks the conflagration spread as far north as the Harz, and eastward to Tirol and Styria; cities, knights, and even princes made terms with the insurgents or joined their ranks. But the want of efficient leadership and discipline soon made itself felt; other princes and knights, with trained soldiers at their back, beat the insurgents in one battle after another, and the main revolt was subdued before the end of 1525, leaving the peasants in a worse plight than before, though the Tirolese held out longer and gained real concessions. Luther at first had sympathized with the insurgents and protested against harsh measures; he even risked his life by going among them and preaching peace and moderation.

But soon their excesses angered and dismayed him; his tract *Against the murdering, thieving hordes of peasants* breathed fire and slaughter. Its pitiless tone may be explained, though never excused, by the disastrous reaction of this social revolt upon Luther's own revolution; the more so, since the rebels had in nearly all cases claimed religious sanctions for the movement. It was therefore evident that the Reformation was bound to emphasize political and social differences. Hitherto it might have been called a national movement in Germany, but henceforward it was a party-question in every sense of the word.

A Religion of State.—The story is complicated by the multiplicity and kaleidoscopic changes of these 300 German States, and especially by the confusion between the two Saxons. Catholicism and Protestantism were exposed to all the gusts of party politics. In Luther himself the prophet often gave way to the politician; and he, who in 1525 had at first insisted that the peasants must be met not with blows but with reasons, was soon ready to call upon secular princes to draw the sword against all enemies of the Reformation. He had begun by insisting on responsibility to God alone; but now with most of the Reformers, he ended by subordinating Church to State. In July 1525, a league of Catholic princes was being formed to quench the Reformation in blood; in October, the landgrave Philip of Hesse began to frame a defensive league of Protestant princes. This support could be bought only by abandoning absolute freedom of private judgment and by allowing many ecclesiastical endowments to be secularized. In order to avoid offending the landgrave, Luther, Melancthon and Ruer-

agreed in allowing him to commit bigamy; a concession which may be paralleled by a few similar licences from popes, but which, coming from these Reformers, justly scandalized the public more than the papal actions. On both sides, Catholic and Protestant, self-interest now played a very great part.

The ups and downs may be very briefly summarized. "The Diet of Augsburg (Dec. 1525) did little. That of Speyer (June 1526) refused to execute the edict of Worms, and procured the decision that each prince should so act in matters of faith as to be able to answer for his conduct to God and the emperor. This gave the Reformers a most valuable breathing space, but the Catholic States were presently provoked into organizing persecution against heretical subjects; the emperor, having now made up his private quarrel with the pope, was determined to fight the innovators, and a diet at Speyer (1529) altered the tolerant decree of 1526. Six princes and 14 cities read a solemn protest at the diet against this vote; and the action of this small minority gave to the party that name of Protestant by which it has ever since been known.

Schmalkalden.—For the Diet of Augsburg (June 1530) Melancthon drew up a confession, which minimized the differences between Lutherans and Catholics, and exaggerated those which separated Luther from the more radical Swiss reformer Zwingli. The emperor granted a respite till April 15, 1531. By that date, eight princes and 11 cities had formed at Schmalkalden a defensive league for six years. The emperor, more and more hampered by the Turkish peril, finally granted the "Peace of Nuremberg (July 1532) which guaranteed the Protestants from molestation until the next general council of the Church. But Clement VII. was in no haste to call such a council; he feared the emperor's encroachments scarcely less than Luther's heresy; and, meanwhile, Protestantism gained much ground, though in Switzerland it had received a check in the death of Zwingli. When at last the general council, in spite of dissensions among the orthodox, seemed imminent, the Protestant princes refused to attend it; they renewed the Schmalkaldic League (1537) and were joined by fresh allies. The emperor formed a counter-league (Nuremberg, 1538) and war seemed imminent, when a compromise was arranged at the Diet of Frankfurt (1539).

A series of conferences, from 1540 onwards, produced no real agreement. In 1544 the Peace of Nuremberg was formally prolonged for another five years; but the continual spread of Protestantism, not always without a violence equal to that which their enemies were prepared to exercise, precipitated a struggle. The long-delayed council of the Church had at last met (Trent, 1542); but the Protestants refused to attend it. The emperor declared war; the Protestants were beaten at Mühlberg (1547), and promised to send representatives to Trent, but were freed from that undertaking by Catholic dissensions. At the Diet of Augsburg (1548), Charles drew up on his own responsibility a sort of compromise, the *Interim*; and in 1551 the Protestants sent representatives to Trent.

But the *Interim* was naturally unpopular on both sides; and, next year, Maurice of Saxony took advantage of the emperor's twofold embarrassments with France and Turkey to turn suddenly against him; he almost succeeded in taking him prisoner. Charles, foreseeing defeat and shrinking from the humiliation, soon transferred to his brother Ferdinand of Austria the direction of German affairs (1554). Maurice was killed in the moment of victory at Sievershausen; John Frederick of Saxony died soon afterwards; but Protestantism was too deeply rooted to be shaken.

"Cuius regio, eius religio."—While the Diet of Augsburg was hesitating to grant religious peace, a rival assembly at Naumburg was attended by more princes than the diet itself, and decided to abide by the confession of Augsburg (1555). (See AUGSBURG, CONFESSION OF.) The diet, after many struggles, agreed to one of those compromises which leave seeds for future war. It consecrated the principle *cuius regio, eius religio*; each prince might choose for himself between Catholicism and Protestantism; his subjects must submit to that choice unless they preferred to emigrate. We must here end the story of the Reformation in Germany. The mere fact that Catholicism had been compelled, over and over again, to negotiate with Protestantism on something

like equal terms, was a death-blow to the mediaeval conception of the Church. Now, by this Peace of Augsburg, Protestantism was actually legalized for about half the population of Germany; and this proportion has since maintained itself with little alteration.

SWITZERLAND

Switzerland had broken loose from the empire in 1499; and here was plenty of fuel for Luther's spark. Ulrich Zwingli (b. 1484) was ordained priest in 1506 and soon distinguished himself as an opponent of moral abuses both in the Church and among the laity. In 1518 he succeeded in expelling the indulgence-seller of St. Peter's from the canton of Schwyz; and was promoted to the great minster of Zürich. Here his learning and zeal, aided by the strongly democratic tendencies of this city of Zürich, made him into a combination of prophet, priest and politician. The burghers of Zürich had long exercised a disciplinary control over their clergy which was far from usual; and here also was an important printing press. Zwingli, in his campaign against the wholesale enlistment of young Swissers as mercenaries for foreign countries, was bold enough to preach also "that it is no sin to eat flesh on a fast day, though it is a great sin to sell human flesh for slaughter." This brought him into conflict with the bishop of his diocese (Constance). In 1522, by a custom general among the Swiss clergy, he contracted a connection with the widow of a citizen, and joined with ten other priests in a petition to the bishop against the law of celibacy, on the ground that this was commonly broken in Switzerland. In April 1524 he married her publicly, in defiance of the Church.

Meanwhile the magistrates had arranged a public disputation between orthodox and innovators (Jan. 1523). More than 600 clergy and representative laity attended, and the magistrates decided in Zwingli's favour. In consequence of a second disputation in the autumn, all church pictures and images were abolished; presently the monasteries were disbanded, and their funds devoted to schools and the poor. The neighbouring canton of Lucerne sent to warn Zürich against its heresies; threats were added, and Zürich began to prepare for war. In 1525 a new form of liturgy was prescribed, severely puritanical; and in 1529 the Catholic worship was forbidden.

Division.—Meanwhile the revolt spread to other cantons. At a disputation at Baden (May 1526), which Zwingli refused to attend, 82 clerical representatives voted for the conservative side, as against 20 reformers. Yet the movement went rapidly forward, in spite of Zwingli's quarrel with the more conservative Luther, and of the set-back which followed here, as in Germany, upon the Peasants' Revolt. The forest cantons, with their comparatively primitive and scattered peasantry, were naturally on the conservative side; they had formed an anti-heretical league (April 1524); and in Zwingli the prophet became more and more overshadowed by the politician. Between 1527 and 1530 Zürich succeeded in creating a league of the greater Protestant towns, to which the five forest cantons replied by a "Christian Union" (April 1529). Each party was ready to ally itself with the foreigner; Zürich with France, the Union with Austria. The Swiss confederacy was thus broken up into two opposing camps. The Catholics were unable to accept the full principle of mutual tolerance; and Zürich also was aggressive and intolerant. The two armies faced each other at Kappel, but peace was patched up (June 1529). This was only a truce; they met again at Kappel, where Zwingli was defeated and slain (1531). The peace now made granted to each canton the choice of its own religion, and did much also to protect minorities. The country soon settled into much the same division which still obtains: Catholicism reigned mainly in the mountains and Protestantism in the more fertile lands and in the great cities.

Geneva.—Geneva (not yet in Switzerland) deserves separate mention: it owed everything to its neutral position and to the personality of John Calvin (q.v.). The Genevese had lived for centuries under a prince-bishop, though with a good deal of democracy in their civic constitution; thus State and Church were more closely interwoven here than in most other cities.

In 1530 the city rebelled against its bishop; in 1534 it entered

into a contract for joint citizenship with Protestant Berne; in 1536 it formally committed itself to Protestantism, and two months later Calvin settled in the city. He was a man of precociously wide and exact scholarship, bred in the law, and touched with inspiration from Erasmus and Luther at the age of 24 (1533).

Calvin's "Institution."—Next year he fled from France; in 1535 he was at Basel, where he wrote in Latin his *Institution of Christian Religion*, which he afterwards turned into French. This epoch-making book has often been misrepresented. Calvin's insistence upon the torments of hell is merely the orthodox mediaeval doctrine, in a far milder form than we find it (for instance) in St. Bernardino of Siena. His insistence upon predestination does not go far beyond St. Thomas Aquinas, whose actual words are often softened down by his modern exponents. The great value of Calvin's book was that it gave a clear and logical structure to a hitherto formless and disorganized Protestant thought, much as St. Thomas and his fellows had constructed a logical synthesis from the heterogeneous mass of Catholic traditions.

In July of 1536 Calvin passed through Geneva, where the reformer Guillaume Farel persuaded him to stay. He introduced into the city, now an independent republic, a discipline which, like his *Institution*, may easily be misunderstood. His supervision of morals and expenses and amusements was no new thing; there is practically no detail in that field which had not been insisted upon by orthodox mediaeval theologians for centuries past, and written in town statute-books, and sometimes even enforced in practice. Here, Calvin's innovation was to substitute stern regularity for impulse and caprice. For the matter was now in the hands of business men; the bishop having been driven out, this enforcement of discipline devolved upon the town council as wielders both of ecclesiastical and of secular authority.

And behind that was another revival from the past. Anxious as Calvin was to revert to the Christianity of the earliest days, and finding as he did in the Lord's Supper the central Christian rite, he insisted on the rejection of unworthy communicants. This regulation proved too stringent for many others besides the "libertines"; and Calvin, with his two chief colleagues, was banished in 1538. The city recalled him in 1541, and he obeyed, most unwillingly, for the sake of what he regarded as a great public work. His *Ecclesiastical Ordinances* and his institution of the *Consistory*, became in one sense the parents of Presbyterianism (q.v.). The discipline which had always been advocated was now actually enforced; and nonconformists were punished, sometimes even to the death; the world will never forget how this rebel Calvin burned the Unitarian Servetus. But he saw that a Protestant ministry could never hold its ground without solid learning; therefore he wrote a catechism which should teach even children to give reasons for their faith; moreover, he founded a grammar-school and an academy which attracted able men from all lands, and which sent missionaries out in all directions.

FRANCE

In France, as in Switzerland, the germ of the Reformation is pre-Lutheran. The concordat of 1516 had put the French Church practically under royal authority; the Renaissance (q.v.) was rapidly sapping mediaeval conventions; and one very remarkable man devoted himself with equal enthusiasm to religious reform and to learning. This was Jacques Lefèvre (Faber Stapulensis), who in 1512, at the age of about 55, published a Latin translation of the Pauline epistles, with a commentary which roughly anticipated Luther's theory of grace and his denial of transubstantiation. In 1524 Lefèvre revised a French translation of the New Testament, as a forerunner of the whole Bible. He was now under the protection of his old pupil Briçonnet, bishop of Meaux, who had set his heart on the reformation of morals and religion within that diocese. With the help of other pupils, such as Guillaume Farel, Lefèvre created a whole school of students and evangelical preachers.

Meanwhile Luther's doctrines were spreading in France and had been formally condemned (1521); and in 1523 the bishop of

Meaux found himself obliged to fulminate against Luther by name, and against certain doctrines held by Farel and other extremists. Then the *parlement* took strong measures against the innovators: Lefèvre's Testament was burned, while he and his friends found safety in flight. Heresy spread rapidly, and Francis I. favoured or punished it according to the changes of the political weathercock. At the end of 1533 he decreed instant burning against any man convicted by two witnesses of being a Lutheran; but the next January he signed a secret treaty with the Protestant princes of Germany.

Then the excesses of the wilder reformers, who placarded Paris with an offensive broadside against the mass and the priests, caused a natural reaction among the people and at court. In two months, nearly 200 heretics were in the Paris prisons, and eight had been burned. When Lefèvre died (1536) "partly from the timidity of the leaders and partly from the rashness of the rank and file, the first or Evangelical phase of Protestantism in France had failed to bring about a reform of the Church" (A. A. Tilley in *Camb. Mod. Hist.*, vol. II).

In that same year Calvin published his *Institution*, with which the second, or Calvinistic, phase began. The book supplied the Protestants with a clear and detailed theory of religion; on the other hand, it involved a considerable recoil from two most important principles: it set definite limits both to free enquiry and to individualism. Thenceforward French reformers shared the strength and the weakness of institutionalism. More truly in France than in any other great country, Geneva now became "the Protestant Rome."

The Waldensians.—After a lull, persecution became more severe again (1538-40). The theological faculty of Paris drew up 26 articles of faith in answer to the *Institution*, which Calvin had now published in French, and which was solemnly burned in 1544; meanwhile, many Calvinists were burned here and there. In 1530, the Waldensians (Vaudois) who had survived from mediaeval persecutions in a group of 30 remote mountain villages along the Durance, affiliated themselves to the Lutherans; therefore in 1545, after varying negotiations, an army was sent against them without warning; 22 villages were burned and 3,000 men, women and children were killed.

A still deeper impression was made by the *auto-da-fé* of Meaux (1546) because this was a solemn and judicial act. Sixty persons were here arrested for the crime of having celebrated the Lord's Supper in Protestant fashion; all but ten were punished; 14 were tortured and burned. Even this did not drive the new doctrines altogether underground; other executions took place elsewhere; but meanwhile missionaries and pedlars were secretly preaching and distributing forbidden pamphlets in every province except far-off Brittany. After ten years of this, Francis I. died, and Henry II. sharpened the persecution, by creating an anti-heretical committee of the *parlement* of Paris, which became known as the *chambre ardente*. This condemned at least 100 persons to death in 3 years; and the provincial *parlements* followed suit.

Yet Protestantism still grew; and in 1555 it began to organize itself; churches were founded on the model which Calvin had framed for Strassburg, and in 1559 a General Synod met, representing from 40 to 50 churches. The Government now procured papal approbation for an Inquisition after the Spanish model; but the Paris *parlement* was not prepared to go so far. Meanwhile the new doctrines were taken up by some of the higher nobility; they thus acquired the advantage and the disadvantage of becoming both fashionable and political. The execution of a distinguished member of the *parlement*, Anne du Bourg, for merely protesting against persecution (1559), could be described by an eyewitness as "doing more harm to the Catholic Church than 100 ministers could have done." But the "tumult of Amboise," next year, redressed the balance. The Government, during the boyhood of Francis II., had fallen into the hands of the Guise family; and a number of Protestant nobles conspired at Amboise to arrest and imprison these unpopular rulers. The plot failed and brought natural discredit upon the religious cause.

A Political Party.—Protestantism was now becoming almost as definitely a political party in France as Catholicism; therefore,

a council was held at Poissy, virtually representing the whole nation, to find a *modus vivendi* on the basis of mutual toleration. The Protestants were represented by 12 ministers and 30 laymen; the Catholics by six cardinals and 64 prelates or doctors; the king presided, with the queen mother and princes of the blood. The conference failed to effect a compromise between irreconcilable doctrines; but it was followed by an edict granting liberty of conscience within certain definite limitations. This, however, without fully satisfying the Protestants, was enough to exasperate the Catholics.

In March 1562, the former were holding a religious service in a barn at Vassy, in spite of the edict which forbade their worship in any walled town. The duke of Guise, passing through the town, sent his men to expel them. They resisted, and the soldiers stormed the barn, killing 63 of the worshippers and wounding 100 or more. The example of this "massacre of Vassy" was followed in many other places; henceforward the Wars of Religion began, and we can no longer treat the French Reformation as a purely spiritual movement. The massacre of St. Bartholomew was a natural sequel to the tumult of Amboise and the massacre of Vassy. But, before quitting this subject, we must note that the "Presbyterian" constitution owes even more, directly, to the French Protestants than to any other source. Their "confession of faith" and their "book of discipline," though founded essentially upon Calvin, have more directly influenced the Dutch, Scottish and American churches, than Calvin's own constitution at Geneva.

THE NETHERLANDS

When we have thus followed the German, Swiss and French Reformations, we find little that is new in other Continental countries. The Netherlands were well prepared for Protestantism by their busy civic life, their early welcome of the printing-press, their vernacular translation of the Bible (1477), and the educational work of the *Brothers of the Common Life* or *Common Lot* (see *BROTHERS OF COMMON LIFE*; GROOT, GERHARD). Luther's writings were welcomed at once; and the Bible was frequently printed in Dutch, Flemish and French between 1513 and 1531.

Charles V. began with public burnings of Lutheran books *en masse*, and then established the Inquisition (1522). Burnings for heresy began early; but the emperor's edicts, though severe and frequently repeated, were difficult to enforce in face of the growing opposition. Special severity and peculiar tortures were reserved for the Anabaptists, who were intercepted and slaughtered in large numbers even when they attempted to emigrate. At last, in 1534, they were provoked to strike back, but with the natural result of severer persecution. Under Philip II., political and religious oppression were intertwined. When, in 1565, he insisted on the publication of the decrees of the Council of Trent, not in the pope's name but in his own, Holland and Brabant protested against this as an infringement of their constitutional liberties. Next year, a confederacy of nobles and leading citizens pledged themselves to resist the Inquisition, and adopted the nickname of *Gueux* (g.v.) which the courtiers had fastened upon them.

In July, Philip promised to withdraw the Inquisition and grant such tolerance as his conscience would permit; but the secret archives of Simancas show that he wrote simultaneously to the pope and explained this promise as a mere ruse to gain time. At that point, a series of iconoclastic outrages by the Protestant mob gave a legitimate handle to the Catholics. The duke of Alva was then made viceroy by Philip II.; he proclaimed heresy as high treason and inaugurated a reign of terror (1567); from that time forth the struggle became political; religious discussion was merged in civil war.

DENMARK AND SWEDEN

In Scandinavia the revolution was comparatively bloodless. King Christian II. of Denmark imported a Lutheran preacher in 1519, and would have welcomed Luther himself; he published new codes of law which no pope could approve. But he became unpopular, fled from his kingdom in 1523, and was reconciled to the

pope in 1529. Meanwhile Frederick I., proclaimed as his successor, made peace with the clergy; but Lutheran doctrines still spread; and, Frederick believing himself to have been tricked by the pope in the matter of the archbishopric of Lund, was confirmed in his own growing inclinations towards Protestantism.

His son Christian and his son-in-law Albert of Brandenburg had already declared themselves and in 1527 Frederick met the solemn remonstrances of the bishops with the reply that faith is free, and that each man must follow his own conscience. In 1530, 21 Lutheran preachers, accused of heresy, offered to dispute publicly in Danish against the accusing bishops, who, however, refused to discuss religious questions in the vernacular. Frederick's son Christian III., in 1536, abolished the bishops' authority, seized their possessions, and imported a disciple of Luther, Bugenhagen, as his chief ecclesiastical adviser. Much of the ancient ritual was preserved; and, though there was inevitable friction between the two parties, this systematic and authoritative change of official religion avoided civil war, and brought Denmark higher in commerce and in learning than she had ever stood before. Frederick and Christian made corresponding changes in their subject lands of Norway and Iceland; but here the ancient abuses had been less crying; the people were less ready for change; so that the revolution thus forced upon them from above caused perhaps as much evil as that which it professed to remedy.

In Sweden also the royal initiative secured a bloodless change. Gustavus Vasa (1523-62) had made the acquaintance of Lutheran preachers before his accession; and political necessities led him to look towards disendowment of the Church. A public disputation in the king's palace (1524) went in favour of the reformers; between 1526 and 1547 the whole Bible was published in the vernacular; and men could henceforth judge better for themselves between the rival claims. The diet of 1527 decided in favour of Lutheranism and disendowment. The next king showed some preference for Calvinism; and John III. (1568-92) proposed reunion with Rome. John's son had adopted Catholicism; therefore the people resolved to secure themselves before his formal accession. A synod of lay folk and clergy was held at Upsala; it decided to accept the Bible as the supreme authority, adopted the Augsburg confession, and restored Luther's catechism as the foundation of all religious teaching.

ITALY AND SPAIN

In Southern Europe, in Italy and Spain, Protestantism enjoyed no princely protection of any importance, nor (perhaps on that account) did it ever spread far enough to gain a hold upon the people. Here, as elsewhere, orthodox reformers constantly fell under suspicion because orthodox and radical reform were so difficult to reconcile in practice. The celebrated *Counsel for Amendment of the Church*, drawn up in 1537 by a papal commission of cardinals and other distinguished theologians, insisted that dispensations from Church law should not be so frequent, and should never be given for money. Yet one of these same cardinals, Caraffa, when raised to the papacy as Paul IV., condemned the document in 1559 by his Index of Prohibited Books, while three of the other cardinals (Sadoleto, Contarini and Pole) fell under suspicion of unorthodoxy in later years. Many Italian reformers were thus driven over the line; others protested their loyalty to the law.

The Triumph of Orthodoxy.—The Inquisition, in both countries, was a deciding factor. Into Italy it was reintroduced in 1542 by Cardinal Caraffa, who, when raised to the papacy, worked it with increasing severity. Although Naples and Venice refused to grant it full powers, yet, even there, it was strong enough to prevent any real organization of Protestantism; while in the principalities of Ferrara, Modena and elsewhere heresy was always struck down before it could mature; at Modena 14 persons were burned in the single year 1568. Many fled abroad; in Switzerland there grew up a considerable Italian community; some of these, persecuted by Calvin for their extreme radicalism, fled into Poland and contributed to the spread of Unitarianism.

In Spain, orthodoxism triumphed still more easily. Cardinal Ximenes (d. 1517) had, by the most drastic disciplinary action,

raised the Spanish clergy far above the general European level of morals and learning; consequently there was a strong party in his attack could accuse even Erasmus of wild exaggeration in his attack upon Church abuses; distinguished men were condemned for favouring "Erasmic" propositions. Secret communities of Protestants gradually formed at Seville (where we are told of nearly 1,000 members) and at Valladolid. But two *autos da fé* (1559-60) burned 24 men and women at Seville; two others (1559) burned 27 at Valladolid; there were other sporadic executions, and the Spanish non-conformists, like the Italian, could find safety only in flight. In Portugal, where the Inquisition was even more rigorous, we can scarcely guess what might have been the result if anything like private judgment had been possible for the people; what actually happened was that the country produced very few Protestants.

GREAT BRITAIN AND IRELAND

The English story is peculiar in one most important particular. In its beginnings, the Reformation was strongly political, yet not anti-Catholic; Henry VIII's ideal was "the papacy without the pope."

Here, as in Germany, the ground was well prepared. Lollardy had been driven underground; but it was still very far from complete extinction. The clergy were, on the whole, unpopular, especially in London. The bishop of London wrote to Wolsey in 1515: "Assured am I, if my chancellor be tried by any [jury of] 12 men in London, they be so maliciously set in favour of heretical pravity that they will cast and condemn any cleric, though he were as innocent as Abel." And Charles V.'s envoy, Chapuys, reported to his master from London in 1529: "Nearly all the people here hate the priests." Here, therefore, as in many other parts of Europe, the mediaeval concordat between Church and State was already breaking down.

And here also the Renaissance had already begun to undermine the old fabric. In 1516, More told Erasmus that the *Epistolae Obscurorum Virorum*, a bitter satire upon the monks and the traditional philosophy, was "read everywhere" in England. Erasmus's own writings had enjoyed great popularity; and Colet, dean of St. Paul's, supported the new learning against tradition with a boldness which naturally started other men upon still bolder courses; moreover, More's *Utopia*, published in 1516, was almost as revolutionary on the theological as on the social and political side. All religions are tolerated in Utopia, and almost all religious discussion. For in this country "nothing is seen or heard in the churches, but that which seemeth to agree indifferently with them all. If there be a distinct kind of sacrifice peculiar to any several sect, that they execute at home in their own houses." Wider knowledge of the universe was beginning to break down that mediaeval condemnation of all non-Christians to hell; and this breakdown must, sooner or later, involve a break with yet other mediaeval tenets.

The "Defender of the Faith."—Therefore, when Luther came forward, his works found an early welcome in England; and in 1521 Henry wrote a Latin treatise against the heresiarch which earned him from the pope the solemn title of "Defender of the Faith." Heretical books were burned in St. Paul's churchyard, and four heretics were burned in the diocese of Lincoln, while 50 more abjured their creed. But Lutheran groups began to form at the two universities, especially at Cambridge; which produced eight leaders of the new movement. Here, in 1525, the prior of the Austin Friars, Dr. Barnes, preached a sermon which caused his prosecution for heresy; he was compelled to abjure at St. Paul's, in company with four German merchants. But, a year later, the king was planning a divorce and remarriage, since it was politically necessary for him to have a definite heir to the throne.

This has often been represented as a mere piece of sensuality; but the facts speak plainly to the contrary. There was nothing to prevent Henry, if he had wished it, from keeping a barren like those of his contemporary Francis I. in France and his successor Charles II. in England. Moreover, before the question of Catherine's divorce came up, Henry was already taking very strong measures in another direction; he heaped honours upon his one

known illegitimate son, Henry Fitzroy, and planned, with the advice of his council, the proclamation of this six-year-old boy as heir to the throne. But the plan broke down and Henry's attachment to Anne Boleyn now contributed to suggest the other expedient of a divorce from Catharine. (In the strict technical sense it was not a *divorce*, but a *decree of nullity*; however, the briefer term was very commonly used then, as since.)

This complicated story may be reduced to a few simple issues. In the minds of all the principal actors except Catharine, the problem was mainly or wholly political. The king needed a male heir; and his counsellors augured disaster to the kingdom from a female or a disputed succession. So also with Rome; Clement VII. himself was long in making up his mind as to the Catharine case; and most significant of all, he actually suggested in 1530 that the problem might be solved without divorce, by allowing Henry two wives at once. (A. F. Pollard, *Henry VIII.* [1905], p. 207.) Even if, as some of Henry's advisers suggested, this was merely a diplomatic feint, it is no less significant in this present connection. Henry had thought of the proposal seriously at an earlier stage, and based it upon Old Testament precedents. As Pollard points out, Eugenius IV. had actually granted similar licence to Henry IV. of Castile, for similar political reasons, in 1437. For the pope's real difficulty was not in the moral problem of the Boleyn marriage but in the political problem of the divorce, since Catharine was aunt to the most powerful sovereign in Europe, and the one from whom Clement had most to fear personally. Therefore the pope evaded all definite decisions, shifting in response to the shifting political situation, for three years (1527-29), when at last he transferred the case to Rome.

Then, at Cranmer's advice, Henry appealed to the universities, and, apart from Oxford and Cambridge, eight of the greatest in Europe decided for him (Paris, Orléans, Bourges, Toulouse, Bologna, Ferrara, Pavia and Padua). However much we may discount these verdicts by royal pressure and other evidence which suggests bribery by both parties, yet on the whole "these opinions must stand for the general opinion of the learned, unless the divines of France and Italy were more generally venal than is commonly supposed" (H. M. Gwatkin).

Supreme Head.—Already in 1529 Henry had begun to permit the circulation of anti-papal German pamphlets as a threat to the pope; and had even allowed his envoy to hint at further Lutheran developments. Next year, the bishop of Norwich complained of the impossibility of destroying heretical books so long as many folk believed the king to favour them. But at that very moment Henry was taking public measures against heresy, burning Tyndale's New Testament, and forbidding all English Bibles until a version should be made "by great, learned and Catholic persons." This last (as More confessed about the same time) was a great desideratum; yet no such orthodox version was made, or even attempted until long after England had broken finally with Rome (1582-1609).

Already, in 1529, Henry had begun an attack upon the clergy, probably upon the advice of his new minister, the adventurer Thomas Cromwell. Taking advantage of their notorious unpopularity, Henry considerably curtailed the clerical exactions of which lay folk were complaining, and restricted the evils of plurality and non-residence. It was made a penal offense to evade this statute by seeking dispensation from Rome.

Next year, came a still plainer step. Henry, under form of law and without real justice, condemned the clergy of England for having allowed the papal legate to set up his court in England, in violation of the Statute of Praemunire. He extorted not only an enormous fine, but also an acknowledgment in the convocation of Canterbury that the king is "only and supreme lord [of the clergy]," and, as far as the law of Christ allows, even supreme head." But this weapon rested in its sheath until the parliament of 1532.

In this parliament, by means which cannot be palliated except on the plea that they were usual in the politics of that day, and that his adversaries were not more scrupulous, Henry first forced convocation, the parliament of the clergy, to accept three articles which definitely submitted Church to State in England. He then

procured from parliament a statute abolishing "annates," one of the most lucrative sources of papal revenue from England; this, however, he held in his hand at first only as a menace to Rome, until he had procured papal bulls of approval for the election of Cranmer as archbishop of Canterbury. Next, he procured a statute declaring the king supreme head of Church and State, and forbidding all appeals to Rome. Then, by a capitulation even more humiliating than the previous "submission of the clergy," convocation, at Henry's demand, declared the nullity of Catharine's marriage. There was a mock-trial of the case at Dunstable, and Henry, who had already secretly married Anne Boleyn, was now free to make her his queen. How he then succeeded in defying papal excommunication, and in preventing any papal crusade being launched against him by the Catholic princes of Europe, is a purely political story. Before parliament dissolved, it passed a statute forbidding all further payments of any kind to "the bishop of Rome," and "an act for the submission of the clergy to the king's majesty."

The rest of Henry's reign was spent in ruthless warfare against heretics who believed in mediaeval Catholicism less than he did, and against others who believed more than he. His "six articles" of 1539 rehearsed nearly all the main points of the mediaeval creed; to deny transubstantiation was made heresy, and therefore punishable with burning; to deny any of the other five was felony. Consequently the king was burning heretics on the one hand, while on the other he was enforcing obedience to the royal supremacy by beheading Fisher and More.

The Monasteries.—Three causes led him to strike at the monasteries. They were pro-papal, wealthy, and not popular enough to find many defenders. Among the few points of importance upon which historians on both sides are agreed, are two which concern us here: that the monasteries necessarily considered their own cause bound up with the pope's and that one of the most remarkable features of Henry's despotic reign is the absence of organized or determined resistance on the part of the clergy, whether cloistered or not. Henry was extravagant; he wanted money; and here was a comparatively easy prey. Everywhere else in Europe, the civil authority had already been obliged to interfere in the cause of monastic reform.

The articles of reform for English monasteries, which Cromwell issued by Henry's orders, do not deserve the blame which has sometimes been cast upon them. Not only the majority of them, but the most important, were taken straight from the Benedictine rule or from the decrees of popes and other orthodox reformers in the past. When, for instance, Cromwell prescribes "that no monk, or brother of this monastery, by any means go forth of the precinct of the same," he is here only summarizing the plain prohibition in chapter 66 of St. Benedict's rule. When, again, he goes on to command that "women, of what state or condition soever they be, be utterly excluded," this is one of the most time-honoured and frequently repeated of monastic statutes. The only real novelties in this Cromwellian document are the command to accept and preach royal supremacy, and the freedom given to subject monks to complain against superiors who neglect or contravene any of this long list of injunctions.

But Cromwell's visitation of the monasteries is open to far more serious criticism. He chose base agents, who did their work in a base and hasty fashion. It is quite possible that they invented much of their evidence; yet we have irrefragable orthodox testimony to the fact that this unfavourable evidence did not violate probability. The spoils of the monasteries were devoted partly to public purposes, but mainly to pay Henry's courtiers: here England compares very unfavourably with Scotland and some of the German states, where the money went in a large measure to education. Yet, apart from all this which must be said against Henry's unjust and wasteful methods, his dissolution of the monasteries is justified by the experience of other European countries, all of whom, sooner or later, have been compelled to do the same. In Italy and Spain, where Protestantism has been virtually non-existent; in France, where Louis XIV. drove out thousands of Huguenots, and the pastor François Rochette was condemned and hanged in 1761 for exercising his pastoral office; in Austria, where

the small minority of Protestants was either driven into exile or submitted to the same leaden, crushing tyranny which England exercised over the Irish Catholics; in all these countries there has been a wholesale dissolution and disendowment.

The Tudor monasteries were probably in much the same state as that Oxford which Gibbon describes in his autobiography; and if the universities of Gibbon's day had been entrenched behind all sorts of extra-legal privileges; if the students had been as numerous as the Tudor Religious were; and if they had successfully resisted, for at least three centuries, all serious efforts for reform, then we can hardly doubt that they also would have been disestablished and disendowed before now. The dissolution was one of many causes for a rising in Lincolnshire, and for the "Pilgrimage of Grace," in the north, where the people were poorest and least educated, and the monasteries would most be missed. Henry here showed himself a perfidious negotiator and took a very cruel vengeance; but his cause had been supported by many of the higher nobility; and he had no difficulty in getting the shire levies of the south to march against the northern rebels (1536).

Edward VI.—Under Edward VI. religious changes came far more rapidly. Henry VIII. had ended by not only permitting but enjoining the popular study of the vernacular Bible (1536-38) and, though the permission was limited in 1543 to the higher classes of society, yet even this implied a freedom of private judgment quite incompatible with mediæval tradition, and gave an enormous, if not intentional, impetus to Protestantism. Politics, however, played almost more part in the Reformation under Edward VI. than under his father. Reformers were dominant on the council of regency which Henry had appointed; Edward's two tutors, Cheke and Cox, had both been reformers. Under the protector Somerset the chantries were suppressed and confiscated; many of them had also been scholastic foundations in a small way; and thus, though mediæval England had never possessed an educational system in the modern sense, Edward VI. did far more harm to the schools than he stoned for by a few foundations of his own (1545).

Then, in 1548, came deliberate iconoclasm. The party which looked upon images as a hindrance to true religion was stronger now than those who found them edifying, and much regrettable violence was exercised; yet, when we take a wide view, we find that the orthodox Catholic Montalembert is right in pointing out that a larger proportion of mediæval Gothic architecture has survived in England than in France. Edward VI. introduced an English liturgy and a Protestant confession of faith in 42 articles (since reduced to 39); and he permitted marriage to the clergy.

A Return to Rome.—His early death put the Catholic Mary upon the throne, while the country in general was still halting between the rival creeds. She communicated immediately with Rome; Cardinal Pole was sent as papal legate; and both houses of parliament answered affirmatively to Mary's question whether they would return to papal obedience. They next rescinded all the anti-papal legislation of Henry VIII. and Edward VI., and revived the statutes against heresy. Mary was now free for all violent measures.

She had promised, and perhaps intended, leniency; but here was a death-struggle between two incompatible ideals, and, in an age when scarcely anybody believed in toleration, Mary had only one choice. She executed 20 Protestants in her last three years; and, at her death, this rate was rising rather than falling. This was fatal; her very first victim, John Rogers, had been so heartily cheered by the London crowd "that he seemed to be going to his marriage," so wrote the French ambassador to his master. This sympathy, strong from the first, grew in proportion as the queen's desperate efforts intensified. Moreover, a new generation was growing up which was far more widely educated than its ancestors; and this was especially noteworthy with the women.

Elizabeth.—The country welcomed Elizabeth; and, though she was not tolerant in the modern sense, she and her ministers carried through one of the most successful compromises in history, the "Reformation settlement." Elizabeth herself would possibly have preferred a moderate form of non-papal Catholicism, though one of her earliest acts was very significant; she forbade the bishop

who said mass in her presence to elevate the Host, and went out of the chapel when he disobeyed. Many of her subjects were convinced and determined Catholics. But she recognized that Protestantism had come to stay; and she so managed that it should have far more freedom than in any Catholic land, while the Catholics, on the other hand, had as much liberty as the Protestant non-conformists.

Death was the legal penalty for obstinate refusal to take the oath of royal supremacy; but in fact no Catholic who refrained from political plots needed to fear more than a shilling fine for each refusal to attend Sunday service, until after the pope had excommunicated her and decreed her deposition. Scarcely one-fiftieth of the Marian clergy were deprived of their livings for refusing the oath. Therefore the nation settled down rapidly; and the result was a more rapid national advance in learning, in literature and in commerce than at any period since the Conquest. One set of figures may be quoted as typical of the rest. The religious quarrels told very heavily upon the universities. The number of degrees fell sadly at Oxford under Henry VIII., and rose again under Mary to the mediæval average; at Cambridge, however, they fell under Mary. From 1555 to 1558 they averaged only 28 a year; but in 1570 they had risen to 170, and in 1583 to 277, or three times the mediæval average.

Scotland and Ireland.—The Scottish Reformation went on side by side with the English; each assisted the other. John Knox and Elizabeth were far from complete agreement; but they had sufficient sense and self-control to work together. This religious Concordat went far to obliterate ancient enmities; "Knox included in his liturgy a prayer that there might nevermore be war between Scotland and England; and that prayer has been fulfilled" (F. W. Maitland in *Camb. Mod. Hist.*, vol. II.). In 1560 the Scottish parliament did what the English had done a year before; mass and papal authority were formally rejected. Knox's *Book of Discipline*, founded mainly on Calvin's *Institution* and on the organization already adopted by French Protestantism, fixed Scotland in "presbyterianism."

The democratic character of the Scottish Reformation, and Knox's own zeal for education, go far to explain the subsequent love of learning and the high level of general education in Scotland; though the greed of the barons frustrated the hope of endowing a whole system of schools and colleges from confiscated Church property.

England's treatment of Ireland is a black page in Reformation history. The country was conquered, and the conquerors dealt with it after the brutal fashion of that time. Few Catholics lost their lives for religion pure and simple, as apart from political revolts; but a series of unjust penal statutes were enacted, and these, although seldom enforced in their full theoretical strictness, were relaxed far too slowly in the face of advancing civilization; therefore, instead of weakening, they have only strengthened the attachment of the Irish to their religion.

GENERAL RESULTS

It has sometimes been argued that the present religious equilibrium, or something better, might have been obtained without revolution. But this contention seems scarcely reconcilable either with previous or with subsequent history.

We have seen how long this revolution had been brewing. It would be difficult to find any institution which has been so severely criticized by so many of its most devoted adherents, through so many centuries, as the mediæval Church. At the very beginning of the 12th century, St. Bernard had emphasized weaknesses which, if not remedied, must necessarily bring disaster; yet orthodox churchmen of 1500 frequently quote St. Bernard's actual words as exactly applicable to the Church of their own day. Some scandals had been abated; but others were even more rampant. Such improvements as had taken place were mainly due to pressure from the laity; and friction between clergy and their flocks seemed increasing rather than decreasing.

Subsequent history, again, seems to point even more decisively in this same direction. We have seen that the real question at issue was that of private judgment. Nearly all reformers had

two fundamental points in common with the orthodox; they wanted to save souls and they believed in the inerrancy of the Bible. But on one fundamental point they differed; is the Bible to be interpreted by the individual for his own soul's sake, or by the Church for the individual's soul's sake? The reformers acted on the former principle; and this opened the floodgates for the rest; so, although the full claim of private judgment was not the basis on which the reformers consciously took their stand, yet it was implicit in their original theories and in their original actions.

Private Judgment.—Between authority and private judgment, no agreement seems possible except the agreement to differ; yet even that was essentially impossible under the mediaeval régime. To differ publicly from any solemn pronouncement of the Church was a crime; obstinately to differ was a capital crime. Therefore no orthodox mediaeval churchman could grant to others the right of nonconformity, or could really escape from the responsibility (however much he might personally shrink from it) of denouncing and punishing all dissenters. Yet, by 1500 at least, it was becoming quite obvious that considerable numbers of Christians were trusting more to private judgment, confessedly or implicitly, than to the traditional teaching of their priests.

The Inquisition had driven the nonconformists underground for nearly three centuries, very much as early Christianity had been driven underground for nearly three centuries by imperial persecution; and it was now emerging with irresistible force. The pope could not now do what Constantine had done in 324, reversing at a single stroke the policy of his predecessors. To Constantine, this religious question had been only one of many debatable issues, and he may even have looked upon it as one of the least important of his political problems; therefore, a reversal at that point need not in the least imply reversal of the whole imperial machine. To the pope, on the other hand, this question of private judgment was absolutely fundamental.

Moreover, even the strongest of popes was always far more at the mercy of his predecessors' traditional policy, of his court and of his officials, than a strong emperor. The pope had no means of coming to terms with Protestantism but by accepting the basic tenet of Protestantism; the Protestants, again, could have come to terms only by abandoning a tenet which, implicitly at least, was absolutely necessary to their position. And the fact that, after a century of strife, Christendom was, and has since remained, pretty equally divided between these two irreconcilable principles, would seem to prove that no human ingenuity could have kept the parties permanently within one single fold.

And, indeed, this division of parties seems to have worked more than any other factor towards that tolerance which is one of the greatest gains of modern civilization. The general mass of European society had improved greatly, in many important respects, between 1100 and 1500; but in this one matter of toleration there had been painful and continual retrogression. The Reformers, again, at their earliest stage, were compelled to plead for impunity; but, once in power, they proved as untrue to this principle as the Christian Church had proved when the emperors raised it from a persecuted minority to a persecuting majority.

Mutual Toleration.—Lord Acton, in one of his most plain-spoken essays, has insisted on the wickedness of this *volte-face*, and has pointed out that the innovators Luther and Calvin lacked that palliation which may be pleaded for persecutors who had persecuted in defence of tradition. But, whether we agree or disagree with him in condemning the individual persecuting Protestant more severely than the individual Catholic, the fact remains that the principle of private judgment is logically inseparable from the principle of toleration, and that no institution can survive, in the face of a powerful enemy, if it acts in public and systematic and continual violation of its own fundamental principle. There is a painful truth in the contention that both sides have learned toleration only under outside pressure; yet that pressure itself has resulted from the assertion of a principle irreconcilable with mediaeval theory and practice.

Private judgment brought half of Europe into conflict with the traditions of centuries; the resultant wars were indecisive; it became evident that neither side could exterminate the other;

thenceforward both were obliged to seek some way of living together in the same world. The one party has never granted the individual's right to interpret Scripture otherwise than it was interpreted by the mediaeval hierarchy. Even Protestantism, for many generations, did not advance from the claim for individual interpretation of the Bible to the wider modern claim of rejecting, when necessary, some things that are plainly written in the Bible. But Catholics and Protestants and men of many other creeds live together nowadays in far less discord than that which often reigned in the middle ages among professing Catholics.

The Reformation thus becomes one of the most remarkable episodes in world-history, whether we regard it in bulk or in detail. It is rich in striking incidents and in display of human character, both on the Catholic and on the Protestant side; we may find here the loftiest heroism and the lowest depths of turpitude. It exemplifies all the problems of daily life, magnified in proportion to the greatness of the issues here involved. And from the heat of this conflict between two irreconcilable ideals one principle has slowly emerged, theoretically repudiated by one side and too often violated by the other in practice, yet finally victorious through the mere force of circumstances; the principle of religious toleration. The experience of centuries has now suggested that the main differences which separate many minds from the teaching of the mediaeval Church are rooted in human nature itself; and that, however near the two parties may draw to each other in the distant future, no such *modus vivendi* was possible in 1517.

REFORMATORY SCHOOL, an institution for the vocational training of juvenile offenders. In Great Britain this means offenders over 12 and under 16 years of age, who have been convicted of offences which, in the case of adults, would be punishable by penal servitude or imprisonment. The period of committal to a reformatory school is for not less than three years and not more than five years, and not beyond the age of 19. The schools are supported in the main from public funds, are regulated by the Children Act, 1908, and are supervised by the home secretary. The departmental committee on young offenders recommended, in March 1927, the substitution of 17 for 16 as the upper limit of age at the time of committal to a reformatory school and the abolition of the distinction between these schools and industrial schools (*q.v.*). See also BORSTAL SYSTEM. (X.)

THE UNITED STATES

The reformatory system of the United States, as distinguished from the penitentiary or prison system, may be considered under two heads: (a) reform schools and industrial schools for youths under 16 or 18 committed for violations of the criminal law or for the want of proper guardianship, and (b) reformatories for adolescents between the ages of 16 or 18 and 30 convicted of criminal acts. The former is an outgrowth of the houses of refuge, which developed in the early part of the 19th century, under private and charitable organizations.

Beginning with the last quarter of the 19th century, a number of States established industrial schools or State homes for the correction and training of their delinquent youths. The reformatory for older adolescents had its birth in the United States in 1859, when the New York State legislature enacted legislation and appropriated funds to build the New York State Reformatory at Elmira. The Elmira reformatory system of academic and trade training is still regarded as the best of its kind in the United States. Almost every State has at least one reformatory. In

practically all cases the system of discipline, training and release established at Elmira was more or less followed. The indeterminate sentence is an integral part of the U.S. reformatory system. Beginning with 1925 there was a decided trend toward specialized vocational training in connection with the educational work of all U.S. reformatories. In the most progressive reformatories the academic and vocational training was carefully guided by psychological and psychiatric work in the clinics of the institutions. This led to marked improvement in the classification and training of prisoners. It is significant that more and more the clinical studies were used as a basis for determining fitness for release.

The U.S. government opened its first federal reformatory for adolescent male offenders in March 1906 at Chillicothe, O. In 1927 the first Federal Industrial Institution for Women was opened at Alderson, W. Va. Prior to this time, federal offenders of all types over 16 years were received at the federal penitentiaries. The federal government follows the practice of boarding many of its offenders in state reformatories and county workhouses.

REFORMED CHURCHES, THE, are those European churches which during the Reformation undertook to reform their faith and life, as they declared, "according to the Word of God," under the leadership of such men as Huldreich Zwingli, Martin Bucer, John Calvin, Heinrich Bullinger and John Oecolampadius. The movement first began in German-speaking Switzerland and in the Rhineland, spreading quickly to French-speaking Switzerland, France, the Netherlands, Hungary and other European countries. The churches are now world-wide in distribution. The Presbyterian Churches of Great Britain share, in part, these same origins, but are also distinctly British in other ways. The Presbyterians, however, classify themselves as Reformed Churches because of the common heritage. The Reformed Churches call their ecclesiastical polity the "presbyterian" system. The name "Reformed" was originally used by all the Reformation churches, as were the names "Evangelical" (i.e., based on the Gospel, the Gospel) and "Lutheran." Only after the serious controversy over the Lord's Supper (after 1529) did the followers of Martin Luther become known distinctly as the Lutherans and the non-Lutheran Reformation bodies as the Reformed.

Though the term "Calvinistic Churches" has become synonymous with the name "Reformed Churches," John Calvin of Geneva was not the original leader of this phase of the Reformation. Rather he, coming after the first great leaders, Zwingli, Bucer, Oecolampadius, etc., took up their ideas, systematized them, adapted them and improved upon them. He is, therefore, the greatest figure in the history of these churches. Not all his distinctive ideas were adopted by all the Reformed Churches.

Switzerland.—The Reformation in Switzerland may properly be said to have begun by Zwingli in 1519 at Zürich. Zwingli had been deeply influenced by Desiderius Erasmus, and stood closer to Renaissance Humanism than did any of the other great Reformation leaders. His outright break with the Roman Church did not come until 1522. It came then in a form which was to become virtually standard for the entire Swiss Reformation and which was to have consequences of the utmost importance. Switzerland had become a federation of cantons each of which had almost total autonomy in internal affairs. A democratically elected council, or other body, controlled all matters. Ecclesiastically episcopal authority had become vague in most cantons.

When controversy broke out between the reforming preachers and the Roman priests, the council of Zürich assumed jurisdiction. Zwingli demanded that a public disputation be held between the reformers and the Roman clergy, and that thereafter the people themselves, through their officers, should decide which religion to follow. This pattern of debate followed by a vote of the people was used in almost every Swiss city or canton which became Evangelical (Protestant). The civil authorities were established

in this manner as the heads of the churches, though they had actually controlled church affairs in great measure before. This control once established came to have serious consequences.

Zürich became fully Evangelical after a series of major disputations, 1523-25. Basle, following a similar pattern, led by Wolfgang Capito, Oecolampadius and Guillaume Farel, voted in the Evangelical faith the same year. Berne, the most powerful of all the cantons, followed suit in 1528. St. Gallen, Biel and others also made the change in the same manner. Opposition from those cantons which remained Roman Catholic grew, and Zürich and Berne led in the formation of the Christian Civic League in defense of the Evangelical Reformation. Eventually even German cities such as Strasbourg joined, and Hesse and Württemberg became interested. The Roman forces now joined in the Christian union. In the two wars which followed, the Evangelical forces were finally defeated, Zwingli was killed, and the Evangelical advance all but permanently halted. Moreover, political leadership in Swiss Protestantism passed from Zürich to Berne (1531). Evangelical and Roman groups agreed to recognize the right of the other to exist. Heinrich Bullinger succeeded Zwingli at Zürich.

Meanwhile, the controversy over the Lord's Supper (after 1529) had broken the Swiss reformers away from the German reformers led by Luther and had brought the Strasbourg reformers led by Bucer into the role of unsuccessful mediators. After Zwingli's death, Bullinger and the other Swiss reformers came to an understanding with Bucer and even with Philipp Melancthon, but could not do so with Luther. Henceforth no one theological mind dominated the Reformation of the Swiss-German Rhineland, and a great area of tacit agreement came into existence. These reformers remained more Humanistic than Luther was or than Calvin was to be (though he was to be deeply influenced by them). Berne took over and pushed the policy laid out by Zürich of advancing the Reformation by open debate and elections. In the furtherance of this policy it had as agents a number of Evangelical preachers who went everywhere, protected by Berne, preaching and debating in Roman Catholic areas. Guillaume Farel was one of the leaders of these preachers. So successful were their efforts that in 1532 it was possible to call a synod of 230 Evangelical preachers at Berne. Bucer was present as an adviser.

Farel turned his attention to Geneva in 1532 but found progress slow and hard. Only after riots and threats of force by both Catholic and Protestant cantons did Geneva finally agree to hold a public disputation in 1532. The Catholic forces led by the prince-bishop besieged Geneva. Berne by coming into the war saved Geneva and crushed the house of Savoy's forces. This brought Geneva somewhat under Berne's tutelage, with Farel as the religious leader. Farel was unable to get an Evangelical church life established in any real measure at Geneva the first year.

Farel saved the situation by persuading John Calvin, a young French Evangelical refugee, to become his assistant. Calvin had been associated with the "group of Meaux," and perhaps also with the Strasbourg reformers. He had, in addition to great theological and pastoral gifts, unusual organizing abilities. He decided to become Evangelical for political reasons and wished to do so in Zürich and other Swiss cities had; namely, control, and use, the church. Calvin and the other Geneva pastors demanded independence for the church in religious matters and the right to criticize, on moral and religious grounds, the acts of the government and the moral life of the city. The church was, however, to have no authority in civil matters. After three years Farel and Calvin were dismissed by the civil authorities from their pastorates because of this clash of ideas (1538). Calvin became a pastor in Strasbourg.

Geneva dared not return to Roman Catholicism because it would mean the loss of its independence to the prince-bishop of the house of Savoy. Yet, religiously and politically the situation in the city deteriorated. The second year Calvin was asked to return, but he refused. In 1541 Calvin's friends persuaded him to come back. He returned as pastor and teacher.

Work was now begun on the reforming of the church in Geneva. Calvin desired a church based on the Gospel and free to conduct its own affairs, including the right to discipline its members, if need

be, by excommunication. Also, he desired no civil office, but the right to preach and teach on civic issues. No civil officer was to have any hold on the church. The government, however, wished still to control, and to use, the church. In the end, the government temporized, leaving the pulpit free, with no civic office for ministers; but the government of the city constituted the government of the church, thus controlling it in the final analysis. Thus, the civil authorities hired the ministers also, whereas Calvin had wished the people to have this right. Because Geneva did have certain serious moral problems, the authorities gave the church large disciplinary power backed by civil penalties as well as religious. The mediaeval "blue laws" and many other regulations were imposed at once in order to reform the city.

Civil and religious authorities worked together well for a time. However, when the church attempted to discipline members of the upper, ruling class trouble came from the civil authorities. Also, Calvin's insistence upon making Geneva a centre for Evangelical refugees caused great resentment among the "old Genevese" party which resented the coming in of these "foreigners." The group in the city for which the religious change from Catholicism to Evangelicalism had been essentially a part of the move for civic independence made common cause with those who resented religious reform. In 1553 Calvin's cause seemed defeated.

Michael Servetus appeared in Geneva at that very time. He had just escaped from the Inquisition at Lyons, Fr., where he had been condemned for Unitarian views. He was an able and well-known freethinker. In Geneva he was arrested for heresy and tried before the civil authorities. At once this became the test case of the whole struggle between Calvin and his opponents. The trial lasted more than a month. Servetus eventually demanded that he be acquitted and that Calvin be put to death and Calvin's property awarded to himself. As other issues were interjected into the case, Calvin and several other ministers resigned and prepared to leave the city. The authorities now temporized and decided to circularize a number of other European churches asking for advice. The mediaeval idea that heretics were disrupters of society and dangerous prevailed, and all these churches recommended death for Servetus. The opposition now not only lost the Servetus test case but was in a hopeless strategic position. The city authorities burned Servetus, though Calvin and others urged a less cruel death.

Two years later (1555) the civil authorities gave up all control over the internal life of the church, but still held out on the issue of the refugees. When the leaders of the opposition to Calvin were found to be in secret negotiations with the French king their whole cause collapsed. Calvin was then free to settle church affairs, found the University of Geneva, train refugee ministers for service all over Europe and make Geneva the Evangelical centre of Europe. He held no office other than that of pastor of the church, though his influence was enormous. Gradually leadership of the various Reformed Churches passed to Geneva. Calvin died in 1564, and his successor, Theodore Beza, was the acknowledged leader of French Protestantism. Under his successors Geneva leadership declined wholly. By the 18th century Geneva was dominated by the Enlightenment. German Switzerland came to greater prominence. French Reformed leadership was never again great.

During the Reformation most Swiss cantons had each its own state church. This pattern has never been dropped. During the 20th century most of the churches were disestablished in greater or lesser measure, without losing their character of national churches. The Presbyterian form of government in general prevails in these churches. No particular creed is used by any of them, though, in general, they follow the Reformed tradition.

Switzerland has become the international centre of world Protestantism, and the Reformed Churches have contributed much to this ecumenical work. During World Wars I and II the Swiss Churches did much to hold together Evangelical Churches in the warring world. In 1948 the Swiss Reformed Churches formed a federation which included roughly three-fifths the population of Switzerland.

Germany.—Matthew Zell, who had been influenced by Zwingli,

began preaching Evangelical doctrine in Strassburg as early as 1521. Soon he was joined by Capito from Basle, and others. Martin Bucer, who had become an Erasmusian reformer, met Luther in 1518 and became an Evangelical. In 1524 he went to Strassburg and shortly was made pastor. Subject now to influences from Zürich, Basle and France, he gradually moved away from Luther. At the Diet of Augsburg, 1530, he led a small group of Germans and others who sought a middle ground between Luther's and Zwingli's groups. From then on he followed a policy of mediation, first between the various reforming groups, and then between the Reformed groups and the Roman groups. When the Interim was forced on Germany (1548), Strassburg was compelled to become Roman Catholic, and the Reformed leaders were exiled. Bucer and others went to England, and some went to Switzerland. When the Interim was lifted Strassburg was made exclusively Lutheran until 1789.

The course of the Reformed system in Strassburg was, therefore, limited to the period 1521-49. However, during that period some decisive things took place. Strassburg became the centre, within Germany, of Swiss Reformation thought. All down the Rhine valley Swiss-Strassburg influences moved, even into the Netherlands. Calvin found refuge in Strassburg 1538-41, and both gave and received lasting contributions. English Puritans before, during and after the "Marian exile" were permanently affected by this theology of the Rhineland, and Bucer eventually went to England. Without Strassburg's role as a channel the influence of Zürich, Basle and Geneva upon the outside world might well have been rather small. The so-called Reformed Churches might have been limited to Switzerland and France.

Francis Lambert of Avignon, who had been at both Wittenberg and Strassburg, led a brief attempt at a Reformed Church in Hesse. At the Synod of Homberg in 1526 the Reformed plan of pastors, elders and deacons elected by the people had been projected. The church soon became Lutheran, but the ideas set in motion by the synod continued to permeate other regions.

The city of Emden became Evangelical under Reformed leadership in 1526-29. Difficulties abounded until a Polish noble, Jan Laski the younger, who had become a Reformed minister took charge in 1542. He introduced a system which blended German Swiss-Rhineland views with those of Calvin. This form of Reformed thought had a wide influence, since Laski was twice a refugee pastor in England and later settled in the Rhineland.

Elector Frederick III of the Palatinate was, in many ways, the one who really gave the German Reformed Church its great opportunity. During the later years of Melancthon's life, and for some time thereafter, grievous controversy raged among Lutherans between an ultra-Lutheran faction and a more moderate group of Melancthon's followers. The latter were continually accused of being Calvinists, and Melancthon was friendly toward Calvin and the Reformed groups. The violence of the controversy turned many minds toward Calvinism, or the Reformed views.

Frederick made Heidelberg university a centre of Reformed thought, bringing to it men such as Zacharias Ursinus and Kaspar Olevianus. Ursinus had been first a Melancthonian Lutheran and had later come under Peter Martyr and Parel. Frederick commissioned these men to draft a constitution for the Palatinate which would more nearly express the Reformed views. The Heidelberg Catechism (1563) which they drew up quickly became the catechism (in many ways the creed) of all the Reformed Churches. In clarity, depth, simplicity and warmth it excelled any other Reformed confession or catechism. Theologically it was an able harmony of all current Reformed thought. Moreover, while it was not based on the then rising Federal theology, with which Olevianus was shortly to side, it could be fitted into that scheme. In view of its many virtues it is not surprising that it replaced, in time, all other Reformed catechisms.

Ursinus and Olevianus prepared also a directory for public worship for the Palatinate. It was definitely Reformed, being a guide to the right ordering of public worship and not a stated, required liturgy whose forms must be used. Altars and vestments were dispensed with, and the communion table was brought in. The pulpit became the focus of the church's public worship, because

from it the Gospel was proclaimed.

The Heidelberg Catechism was attacked fiercely by the ultra-Lutherans. Soon it was being asserted that those who held its views had no right to toleration under the terms laid down in the Peace of Augsburg, 1555. Frederick fought the issue to a successful conclusion at the Diet of Augsburg, 1566, thus gaining a clear-cut admission that the Reformed Churches had the right to exist parallel to the Lutheran Churches allowed by the diet of 1555. With a persuasive statement of faith, a great champion, the legal right to exist and a powerful elector as their champion, the Reformed Churches enjoyed a period of growth and success.

Despite temporary or local losses, or both, the Reformed Churches spread down the Rhine. The Wetterau counties became Reformed, and at Herborn a famous Reformed university was founded. Bremen also became Reformed, and then Brandenburg (1613) with its capital Berlin. Other smaller areas scattered over the German states also became Reformed.

The Thirty Years' War brought the Reformed territories almost to ruin, and at the Peace of Prague, 1635, the Reformed groups were so wholly betrayed that the war was resumed. The Peace of Westphalia, 1648, recognized explicitly the Reformed Churches and restored the lands of the Reformed nobles. It also recognized Switzerland's independence of the empire. The war, therefore, had been an important event for the Reformed Churches. The revocation of the Edict of Nantes (1685) brought into Germany about 60,000 Huguenot refugees. These greatly strengthened the Reformed Churches. During this same period the French ravaged the Palatinate and greatly reduced the Reformed Churches, which were saved only by the intervention of Brandenburg. Yet, until 1802 serious hardship was their fate.

During the 18th century Pietism, coupled with the Federal theology, gained almost total allegiance among the German Reformed Churches. The form of Pietism was that of the Dutch Churches, and drew these two Reformed groups closer together. Pietism, in turn, was followed by the Enlightenment. (F. D. E. Schleiermacher was of the Reformed Church.)

Beginning in 1817, Prussia united, by three stages, the Reformed and Lutheran Churches in its territories. The first stage was federation, the second (1830) a common liturgy, and the third (1834) allowed each congregation the right to use whichever creed and liturgy it wished (Reformed or Lutheran). The territories were those where the Reformed groups had their greatest strength, Brandenburg, Prussia, Pomerania, Silesia, Posen, Westphalia and the Rhine provinces. Those provinces which joined Prussia after 1817, Hanover, Nassau and electoral Hesse, were not compelled to unite their churches, although Nassau had done so previously at its own order. Small local unions were made in these areas, however. Nonunion Reformed Churches remained in Bremen, Lippe, Alsace-Lorraine, Lower Saxony, etc. Generally speaking the Reformed tradition was overshadowed by the Lutheran in the union.

In 1861 Reformed leaders began to revive, but within the various union agreements, a greater appreciation for the Reformed tradition and ethic. Inner mission work among the poor, sick, etc., also was pushed, as were foreign missions, youth work, etc. A vigorous literature on the Reformed ideals began to appear. World War I and the years immediately following wrought havoc on all German Churches. Old cultural patterns disappeared, and the industrialized, modern secular society emerged. The close connections of all the churches with the German state had become a hindrance, and disestablishment under the Weimar republic was in itself good. However, it came when the churches could least afford the financial and other losses which it entailed.

Beginning in 1918-21 a vigorous theological renewal took place in Germany. The Reformed federation, led by August Lang, brought Karl Barth to Göttingen university. He quickly became the leading Reformed theologian of modern times. As the Nazi regime took over, Barth and Otto Weber of the Reformed federation became leaders in the struggle of the German Churches against Hitler and neopaganism.

World War II brought serious losses to the Reformed Churches. Those regions of Germany where they were strongest fell into the soviet zone of occupation. Moreover, many Lutherans, pressed

by the remembrance of the Nazi persecutions, demanded unqualified adherence to (Lutheran) traditional creeds as a guarantee of future strength for the church. This meant the denunciation of the union in fact if not in law. In Hesse, the Ruhr and other regions of west Germany the Reformed Churches recovered slowly after the war, aided by United States Presbyterian and Reformed Churches.

Prior to World War I the German Protestant Churches, working through numerous missionary societies, had a vast foreign missionary work. After 1918 it was necessary, for financial reasons, that churches in other nations take over this work.

During the height of Germany's power, German Reformed groups spread out over a large part of Europe and also into Russia. Sizeable churches were established in Austria (Vienna), Yugoslavia, and Slovakia; smaller bodies were found among the German settlers in Russia, Lithuania and Latvia. In the territories which were alternately Polish and German in the 19th and 20th centuries there were large Reformed groups. The status of all these groups deteriorated seriously after World War II.

The Netherlands.—Reforming interest emerged in the Netherlands early in the Reformation era. Erasmus did much of his best work at Rotterdam. Moreover, the Brethren of the Common Life and other mystical groups had been active in these areas. From 1513 to 1531 about 25 different translations of the Bible, or parts of it, into Dutch, Flemish or French were published in the Netherlands. Much of the early English Reformation literature also was printed in the Low Countries.

Erasmian and mystical types of reform were soon followed by Zwinglian and Lutheran influences. Communications, and other interests also, bound the Rhineland and the Netherlands together. Hence the Swiss-Rhineland type of reform came to predominate. The Anabaptists and the other reform movements seldom if ever merged, and their influences were felt more at a later period. Charles V, who controlled the Netherlands, instituted the Inquisition there against the Reformation as early as 1522.

The struggle for freedom from Spain was begun by the Dutch as a protest in demand of greater liberties, especially religious, within Charles's empire. Charles was determined to wipe out all heresy, and, while frustrated in Germany, he gave himself to the task in his own hereditary provinces, the Netherlands, with the more fanatic zeal. Eventually, the Dutch nobles (c. 1566), led by William the Silent of Orange, turned against him. When he finally abdicated in defeat and despair, Philip II took over his father's crusade against heresy, but with even fewer prospects of success. One of Philip's generals, the duke of Alva, became a notorious symbol of blind and merciless despotism. William was murdered by a hired assassin in 1584, but by that time the Spanish-Roman Catholic cause had been defeated. The Netherlands became free, and the Reformed Church was established.

During the long struggle the religious situation had also become clarified. The leaders in the war for freedom had been deeply influenced by French Huguenot-Calvinist, political, and religious thought. Lutheran and Erasmian ideas had given way to a theology blended from Rhineland, Geneva Calvinist and French Huguenot influences and ideas drawn from Jan Laski's work. The Belgic Confession of 1561 became the standard creed. Church organization was patterned most nearly after the forms of Laski and the Huguenots, two forms of Calvinistic Presbyterian polity. However, the church was not a national church. The Netherlands was a federation of states with great local autonomy in each state. Each had its own church over which the local authorities had almost complete powers. National synods were provided for in the church's system but were seldom allowed by the various states.

Civic peace had scarcely been achieved before a theological revolution took place in the Dutch Church. Calvinists, in their controversies with Lutherans and Catholics, had carried their philosophical development of Calvin's religious view of predestination (which he shared with Luther) to great lengths. Some Reformed thinkers began to object, among them a Dutch theologian named Jacobus Arminius. Other issues also were involved, especially Dutch political issues. The leader of the ultrapredestinarian Calvinists in the Dutch Reformed Churches was Franz Gomarus.

To solve the issue a synod of representatives of Reformed Churches in all lands was called by the civil authorities. Representatives came from several European countries. James I of England took peculiar interest in the synod and sent representatives from the Church of England. The synod met at Dort in 1618, condemned Arminius' mild views, rejected Gomarus' extreme views and stated in more or less classical form the quasi-Calvinistic view which had become the badge of Calvinists in their polemics with other theologians. The term "Arminianism" became a very broad designation in Europe for any deviation from any essential aspect of Calvinistic orthodoxy, whether or not connected with Arminius' followers or with the original points of controversy.

Though scholastic Calvinistic orthodoxy won the struggle with Arminius it failed to nurture the life of the Reformed Church. Dutch Pietism (anterior to and more churchly and theological than German Pietism) and the Federal theology soon dominated the Dutch scene. In these movements the Canons of Dort were always honoured but also made harmless in practice.

By the 19th century the extreme orthodox groups in the Dutch Church were disaffected by the influences of the Enlightenment upon the church. A series of schisms took place which eventually gave Holland three Reformed Churches, each professing to be the successor of historic Reformed Christianity in the Netherlands. The original church bears the name the Netherland Reformed Church. Two early secessionist groups were the Christian Reformed Church (1834) and the Low German Mourning Reformed Church (1886). These merged in 1892 as the Reformed Churches in the Netherlands. A minority of the early secession, however, constituted itself the Christian Reformed Church (Restored). None of these three churches is now a state church, although the original body is still regarded, in some measure, as the national church. During World War II and the German occupation of the Netherlands much progress was made toward healing these old schisms. After the peace most of this gain was lost.

On all matters of Dutch colonial policy the old original church became a leader of enlightened opinion in postwar times. Political parties and labour unions usually follow confessional lines in the Netherlands. Accordingly the various Reformed Churches have their corresponding political parties and labour unions. This structure has tended to fix the distance between the church and all degrees and forms of left-wing thought.

The Netherland Reformed Church had (in 1948) 1,500,000 members, 1,400 congregations and 2,500 additional preaching points, 1,550 ministers, 4,500 elders and 169 missionaries at 65 stations in the Netherlands Indies and Malaya.

The Reformed Churches in the Netherlands had (in 1948) 324,621 members, 810 congregations and 801 ministers. Missionary work was being done in the Netherlands Indies.

The Christian Reformed Church (Restored) had (in 1948) approximately 35,000 members.

The Dutch Churches followed the colonial expansion of the Netherlands. In the Union of South Africa they became the principal Christian Churches. This, together with the Dutch tendency to have political parties follow confessional lines, threw upon these churches a very large responsibility. With few exceptions, these churches reflected the views of the Dutch South Africans. The post-World War II premier, Daniel Malan, who led the campaign for the total segregation of the population and areas of South Africa on racial and colour lines, was an ordained Reformed minister. The South African Reformed Churches officially approved his policy.

Controversy over doctrinal issues divided the church in South Africa also. There were five distinct bodies in South Africa (in 1948) with an aggregate (white) membership of approximately 895,000 members. A mission church for nonwhite missionary converts had (in 1948) a membership of 132,096.

The Netherlands Indies, prior to its independence, had a Dutch Church of about 300,000 members.

France.—From the beginning the Reformation made slow progress in France. And yet, reforming movements within the Roman Catholic Church had been early in appearing. Before Luther had

emerged as a reformer, French Humanists had created much interest in biblical studies and had aroused a concern for a purer type of Christianity. In time Marguerite d'Angoulême, the sister of Francis I, became the centre of a Humanistic group known as the "group of Meaux." While this group never broke with the Roman Church, and never became outright Evangelical, it did create great interest in reform. Also, members of it, such as Jacobus Faber, contributed much by their writings to biblical and theological studies which the Evangelicals could and did use. Again, a number of the group—Nicolas Cop, Guillaume Farel, etc.—as individuals, left the group and became outright Evangelicals. Moreover, because of her position and her influence, Marguerite was often of aid to all degrees of reforming interests.

Not until 1555 was any real attempt made to organize Evangelical congregations in France. Until that time some had hoped for reform from within the Roman Church, others had looked to the group of Meaux and others had thought the Evangelical cause too weak to organize. Calvin, Farel and Beza, all Frenchmen then active in Geneva, had maintained a deep interest in the French Reform movement. Hundreds of students had been sent from Geneva to evangelize France. By 1560 it was estimated that there were about 300,000 Evangelicals in France, and there were at least 49 organized congregations.

Geneva had indeed been the spiritual guide of these churches, but not their ruler. When, in 1559, these churches moved to draw up a confession of faith, Calvin had demurred, thinking the move too hasty. Nonetheless they proceeded, and informed him that they had used his brief confession of 1557 as a basis, although they had altered it somewhat. This pattern of relationships was to continue to the bitter end: Calvin urging patience, the French Reformed Churches (called the Huguenots) impetuous and often violent. In general the Huguenots followed Calvin's views, yet on many critical matters they made such changes as they wished and when they wished.

The Huguenot alterations on Calvin which became of greatest significance were two: in political theory and in church polity. Calvin had been resolute but cautious on the right of revolution against a civil government. He believed that when a tyrannical king or government attempted to force men to live contrary to the will of God, then, and then only, men might resist—but only through the next lowest, willing, legally constituted, official body or group (i.e., usually a parliament against a king, or a league of cities against a king, etc.). The Huguenots urged that when men felt oppressed in any serious regard by a king, they might individually, or collectively in extralegally constituted groups, resist, revolt and even use tyrannicide.

The second alteration on Calvin's views made by the Huguenots was in the realm of church polity, or government. Calvin's adaptation of presbyterian church government had been worked out for the church of a small city-state. The Huguenots adapted it quite successfully to a national scale. The local congregation elected its minister and a body of elders and deacons who, with the pastor, formed the consistory. These consistories then constituted the provincial synod by electing members to it. The provincial synods again constituted by elected representatives the national synod. Nearly all subsequent forms of presbyterian church organization—European, British, U.S., etc., are directly or indirectly modelled on this Huguenot adaptation of Calvin's Genevan system (which in turn had not been original with Calvin).

Frances I had been no friend of the Huguenots, but under Frances II the Guises and their Roman Catholic followers harried the Huguenots. They in turn leaned, to their great loss, upon certain high nobles. Finally, against Calvin's objections, they organized as a political and military force. In a long series of civil wars (1562-94) which followed, they gained and lost as the fortunes of war came and went. Finally peace came when the Huguenot leader, Henry of Navarre, became King Henry IV of France as a Roman Catholic. This satisfied the Roman Catholic groups, and Henry promulgated the Edict of Nantes, 1598, which guaranteed the Huguenots virtual freedom of religion. During this era of strife had occurred the greatest horror of the Reformation, the massacre of thousands of Huguenots throughout France on St.

Bartholomew's night, 1572.

The French Reformed Churches recovered in great measure from these frightful persecutions after 1598. However, the Edict of Nantes was revoked in 1685. Untold sufferings preceded and succeeded this act by Louis XIV. Despite laws against emigration, more than 250,000 Huguenots fled to Germany, the Netherlands, England, Switzerland and the new world. Those who remained persisted as a virtual underground movement and did not regain their full rights until the Revolution of 1789.

Since the Revolution France as a nation has been quite indifferent to all religions. The French Reformed Churches have grown slowly under great handicaps. The theological upheavals of the 19th century broke these churches into two main bodies, the National Union of Evangelical Reformed Churches (conservative) and the National Union of Reformed Churches in France (liberal). In addition, the Reformed Churches of Alsace-Lorraine were grouped separately under that name. A union of the conservative and liberal unions was achieved in 1939, the Reformed Church of France. The churches of Alsace-Lorraine remained distinct and enjoyed state support, whereas the churches of France proper did not after 1905. A small group of the old conservative union continued under its old name.

The Reformed Church of France had (in 1948) approximately 150,000 members, 528 congregations, 600 ministers and 5,000 elders; missionary work was done through interdenominational bodies rather than through exclusive confessional agencies.

The Reformed Church of Alsace-Lorraine had (in 1948) 22,073 members, 50 congregations, 84 additional preaching points, 47 ministers and 280 elders; missionary work done as by the Reformed Church of France.

Hungary.—The influence of the Reformation was felt early in Hungary. A synod at Erdősd adopted the Augsburg Confession in 1545. By 1567 Reformed views had become so well known that the Synod of Debrecen adopted the Heidelberg Catechism and the Second Helvetic Confession, thus becoming a Reformed Church. Except for minor reverses the Evangelicals made progress in Hungary until 1671. The Magyars had become almost all Reformed. The Counter Reformation era was one of severe persecution for all Evangelicals. Not until Joseph II promulgated the Edict of Toleration in 1781 did respite come. Nevertheless, the Reformed Church had not been destroyed by the persecution. Within the old Austro-Hungarian empire the Reformed Church was of two wings, the Magyar (the larger) and the German. The Magyar people spread rather widely through the old empire, carrying their church with them. Theologically the Reformed Churches were much influenced by German theological scholarship. Within the empire they built up a very large system of schools, elementary to university, and did much for Hungarian cultural life. Through state aid and through other sources the church became possessed of much landed property which was used for income purposes (a familiar pattern in Hungarian life).

World War I broke up the old Austria-Hungary, and the nation of Hungary which emerged after the peace of Versailles was approximately one-third the size of the old Hungary. The Hungarian Reformed Church was now shattered. Within the new nation of Hungary there remained about one-half the church. The other half was now minority groups in unfriendly or even hostile countries. The largest segment, 780,000 in Rumania, suffered grievously for both religious and cultural reasons. The 210,000 in Slovakia suffered less. The small group of 40,000 in Yugoslavia had a precarious existence.

The effect of this dismemberment in Hungary was to foster an extreme type of nationalism, to which the church in part fell prey also. Many of the upper middle class, the professional, the government and the military leaders were in the Reformed Church, Adm. Nicholas Horthy de Nagybánya among them. World War II brought a terrible defeat to Hungary and to all hopes of reuniting the Magyar people and their church. Moreover, it brought about a changed outlook among Reformed leaders. When the Communist government nationalized all church lands (Evangelical and Catholic), Reformed leaders urged that land reform must not be resisted; the church must give up its old privileges, etc. So,

also, the church gave up its schools without strife when all church schools were nationalized. This reaction away from its pre-World War II upper-class nationalism and toward a better understanding with, and vigorous evangelism among, the Communist-controlled working classes caused much international comment. The war losses of the church in life and property were severe.

The Reformed Church in Hungary had (in 1948) 973,393 members, 1,203 congregations and 2,016 additional preaching points, 1,850 ministers (100 of whom were women) and 22,000 elders.

The Reformed Church in Rumania (Hungarian Magyar) had (in 1948) 380,000 members, 719 congregations, 686 ministers and 10,200 elders.

The Reformed Church in Slovakia (Hungarian Magyar) had (in 1948) 20,000 members, 31 congregations and 23 additional preaching points, 31 ministers and 588 elders.

Yugoslavia had approximately 40,000 Magyar Reformed Christians in 1948.

Czechoslovakia.—The Reformed Churches of Czechoslovakia are, as the nation itself, of varied origins. The Czech Reformed body is the Evangelical Church of Bohemian Brethren. The Slovak Reformed body is a wing of the Hungarian Magyar Reformed family (see above under Hungary).

John Huss's attempt at reforming the church ended at the stake in 1415. His followers were crushed in 1434, but underground the cause persisted. During the 16th-century reforming movement the Bohemian Brethren emerged again to flourish for a brief period. In 1547 they were again suppressed, and the Jesuits were given charge of religious affairs in Bohemia. A Bohemian revolt in 1618 began the Thirty Years' War in Europe, and thereafter the house of Habsburg and the Counter Reformation held sway in Bohemia. Thousands of Evangelicals fled the country, and the patriot and the Evangelical leaders were executed. During this Thirty Years' War the population of Bohemia was reduced from 3,000,000 to 800,000 by the frightful excesses of the conquest.

Not until 1781 were Evangelical groups again tolerated in Bohemia. Then only bodies holding either of the two German Protestant symbols (Augsburg or Heidelberg) were tolerated. The old native Czech Bohemian Church was still banned. It remained in existence, however, underground. Moreover, the cause of Czech independence and of the Bohemian Church became intertwined.

When the nation of Czechoslovakia was created by the peace of Versailles the Evangelical Church of Czech Brethren was freed. It became the leading Evangelical, or Protestant, Church in the nation. Its leadership in theological education, social work, etc., was marked. During the crises preceding World War II, Czech patriotism and the Bohemian Brethren again made common cause. When the Nazi army seized Czechoslovakia the consequences for this Reformed Church were severe. Many of its leaders, Joseph Hromádka among them, had to flee. After the war the nation came under a Communist government and the church faced a new crisis. The church had been predominantly middle and upper class, with no great hold on the classes now influenced by communism. Under the leadership of Hromádka the church strove to come to an understanding with the government and with the proletariat in an effort to overcome its previous social stratification and isolation. Considerable criticism was directed at this move from other nations.

The church had (in 1948) 90,000 members, 218 congregations and 296 additional preaching points, 186 ministers and 2,616 elders.

Other European Countries.—Small Reformed Churches, often only a few scattered congregations, are found in Belgium, the Scandinavian countries, Greece, Spain and Portugal. Also, the ancient Waldensian Churches of Italy, together with their branches in Uruguay and Paraguay, have come within the orbit of the Reformed Churches, though preserving their own character.

United States.—The Reformed Church in America.—Dutch settlers were brought to the New York area in 1624 by the Dutch West India company. The first church was founded, subject to the church of the homeland, in 1628. When the English conquered the colony in 1664 they allowed the church of the Netherlands to continue in the area. In 1659 a slight amount of power was granted by the home church to a local governing body of churches called a "classis." Early in the 18th century new movements came, colonial self-

consciousness, the "Great Awakening" revival of religion, etc. The Dutch Church was divided into two groups, one favouring great freedom from the home church, supporting the revival, a local college and the free use of the English language. The other group was extremely conservative and wished to remain a part of the Dutch culture. The colonial group grew more rapidly, and founded Queen's college (later Rutgers university) in 1766.

The two factions reunited in 1771 under a plan which left ultimate authority in the Netherlands but gave great local autonomy. After the Revolutionary War the church became wholly independent under a constitution drafted 1784-92. By 1820 the Dutch language had ceased to be in use. The name Reformed Protestant Dutch Church was changed in 1867 to the Reformed Church in America.

A large migration of Dutch people into the United States about the middle of the 19th century added greatly to the church. Most of these settled in Michigan and other midwestern areas. The church had, therefore, two integrally related though rather distinct groups, one centred in New York and New Jersey, the other in Michigan.

The church had (in 1948) 181,299 members, 743 congregations, 869 ministers and 114 missionaries in Arabia, China, India, Japan and Mesopotamia.

The Christian Reformed Church.—In 1822 a small group withdrew from the Reformed Protestant Dutch Church because of doctrinal disagreements. When the mid-century migrations brought many Hollanders who were members of the Christian Reformed Church of the Netherlands into the United States, these united to form the Christian Reformed Church in America. A new secession from the Reformed Church in America in 1882 brought added strength.

The church had (in 1948) 74,778 members, 312 congregations, 268 ministers and 28 missionaries in China.

The Evangelical and Reformed Church.—(This body was formed in 1934 by the union of the Reformed (German) Church in the United States, and the Evangelical Synod of North America. It maintains contact officially with the other Reformed Churches in the United States and elsewhere, although by the union it became both Lutheran and Reformed.)

Palatine Germans, driven out by the wars between France and Germany, came to the American colonies early in the 18th century. The Reformed Church in the Netherlands aided them for a time. They settled in Pennsylvania and in the Valley of Virginia. Attempts to unite them to the Dutch Church and to the Presbyterian Church failed. Gradually they emerged as a self-sustaining church, 1791-93.

During the 19th-century migrations and the expansion of the American west, new German Reformed bodies arose only loosely connected with the eastern parent body. In 1863 these united in one. Efforts to unite with the Dutch Reformed Churches failed in 1802. Later attempts to unite with the Presbyterian Church in the U.S.A. failed also. Union with the Evangelical Church was achieved in 1934. In 1950 the church was in process of merging with the Congregational Christian Church, although some legal hindrances had appeared. REFORMED EPISCOPAL CHURCH, a Protestant community in the United States, dating from Dec. 1873. The influence of the Tractarian movement began to be felt at an early date in the Episcopal Church of the United States, and the ordination of Arthur Carey in New York, July 1843, a clergyman who denied that there was any difference in points of faith between the Anglican and the Roman Churches and considered the Reformation an unjustifiable act, brought into relief the antagonism between the evangelical Protestant clergy and those who sympathized with the position of Carey. The struggle went on for a generation and with increasing bitterness. The climax was reached when George D. Cummins (1822-76), assistant bishop of Kentucky, was angrily attacked for officiating at the united communion service held at the meeting of the sixth General Conference of the Evangelical Alliance in New York, Oct. 1873. This prelate resigned his charge in the Episcopal Church on Nov. 11, and a month later, with seven other clergymen and a score of laymen, constituted the Reformed Episcopal Church, and consecrated Charles E. Chepey (1836-1916), rector of Christ church, Chicago, Ill., to be bishop.

The church recognizes no "orders" of ministry; the episcopate is an office, not an order, the bishop being the chief presbyter, *primus inter pares*. See also ENGLAND, THE CHURCH OF.

REFORM MOVEMENT, the name given in history to that movement toward parliamentary electoral reform, active in Eng-

land between 1769 and 1832, and in France between 1832 and 1848. Different as the two movements were in character, time (the principal phase of the English struggle was over in 1832, when the movement in France was, strictly, only beginning) and result (the ultimate desideratum of manhood suffrage was achieved in France in 1848 and in England only in 1918), the march of events in either country had a profound effect upon the movement in the other. The following article sketches the course of the movement in the two countries. (X.)

THE MOVEMENT IN ENGLAND

The ultimate, if long delayed, success of "reform," embodied in the great act of 1832 was due to an unanalysable blend of political theory and the logic of concrete fact. The political, social and economic structure of Great Britain had, in short, been revolutionized between 1780 and 1830 before the revolution was expressed in a decisive formative statute. The act of 1832 did not so much impose the new system of an ardent minority on an unprepared country as it translated into the organization of self-government the appropriate machinery for achieving what a majority had already accepted as inevitable.

The System in 1714.—The system of representation existing in 1714 was, like every other major organ of the national life, the deposit of a prolonged historic development of at least eight centuries. The House of Commons in 1714 consisted of 558 members, of whom 513 represented England and Wales and 45 represented Scotland. Ireland (with 100 members) was not included until the Act of Union of 1800, which abolished the separate Irish legislature. The Scottish representation had only been introduced in 1707 by the Act of Union. Of the 513 English representatives 94 represented counties, 415 boroughs, and four the two universities of Oxford and Cambridge; 30 members represented Scottish counties and 15 Scottish boroughs. The English franchises for the counties, and the boroughs differed fundamentally. The county franchise, with trifling exceptions, was based on a 40s. freehold, assessed to the land tax. The borough franchise was amazingly varied and defied reduction to a single principle. Four groups can broadly be distinguished: (i) The "Scot and lot" and "pot wallower" boroughs, where the voters, roughly, were residents rated to Church and poor rate; (ii) the boroughs where every freeman, i.e., enjoying the freedom of the borough, had a vote; (iii) the burgeo-boroughs with the franchise attaching to a certain holding or burgo, and (iv) the corporation-boroughs, where a close corporation was the privileged electoral organ.

The county franchise dated back to 1430. The borough franchise was the haphazard result of five centuries of piecemeal development. The electoral map of 1714 emphasized the enormous preponderance of voting power in the borough representatives. The distribution of the boroughs roughly represented the distribution of population at the end of the 16th century. But by 1650 this distribution had altered, and since then had been altering rapidly, even before the radical redistribution and growth caused by the "Industrial Revolution" (g.v.). The "Reform of Parliament" embodied in "The Instrument of Government" of the Cromwellian period (1654), demonstrated very clearly by its redistribution the admitted hiatus between the existing system and the actual facts. The elaborate analyses made by the "Reformers" of the 18th century revealed these bewildering anomalies. Apart from the contradictions of the borough franchise, which allowed a vote in one borough that was denied in another, custom degenerating into caprice, or avowed manipulation, the distribution of seats resulted in the most astonishing paradoxes. Cornwall, for example, paying 16 out of 513 parts of the land-tax, returned 42 members (two county, 40 borough members); Lancashire, paying ten times as much, returned 14 (two county and 12 borough members). The City of London returned four, as did, also, the united boroughs of Weymouth and Melcombe Regis, with neither landed nor economic interests. In Yorkshire, York city and 13 boroughs, with a total of 7,000 voters, returned 28, while the county, with a total of 16,000 voters, returned two members.

The disabilities imposed by law severely restricted both the electors and the elected. Apart from women, children, lunatics, paupers or convicted criminals, the Nonconformists, the Roman

Catholics, the Quakers, the Jews and agnostics could neither vote nor be elected. In the counties neither leaseholders nor copyholders, however wealthy, could vote. Prosperous cities such as Birmingham or Manchester, which had come into existence since 1600, had no representation, while Old Sarum with seven, or Dunwich, half under the sea, with 14 voters, returned respectively two members apiece. Even in 1714 it was abundantly clear that members of parliament did not represent their constituencies, and that the constituencies still more did not represent the nation. It was estimated in 1793 that, with a population of some eight and a half millions, 257 members (*i.e.*, a majority of the House of Commons) were returned by 11,075 electors; that in 51 constituencies there were less than 50 voters, and that 130 boroughs had less than 300 electors apiece; and that whereas 92 county members were returned by 130,000 voters, 84,000 electors in the boroughs had 421 representatives. "The rotten boroughs," *i.e.*, those which were completely under the control of the Crown or a patron, were admittedly the most indefensible parts of this parody of principles and facts.

The Society of the Friends of the People undertook, in 1793, to prove that the lords of the Treasury, 71 peers and 82 commoners could together nominate 306 out of 558 members, *i.e.*, make a decisive majority. The influence of the Crown, *i.e.*, of the Government—through the patronage of the navy, army, Church, judiciary, civil and colonial services—was enormous, and secured the steady voting support in the Commons without which no administration considered itself safe or even possible. In 1770 there were 192 place-holders in the Commons. "Vested interests" in the whole system, indeed, were so strong and deeply-rooted that nothing short of a complete organic change in the social and economic structure could compel a House of Commons to accept "reform" which meant the extirpation of a half of those who sat in it, with the lucrative possibilities that membership offered. It follows from this brief summary that the would-be "reformer" of the 18th century, with so large and easy a target to attack, but which covered such a variety of interests, had really to prove that the "system" resulted in bad government, and that in the major issues of the national life the welfare of the unrepresented was more important than the welfare of the minority and was being continually sacrificed to it. Before the political theory of Locke, Blackstone and Burke could be dissolved a new political theory had to be created and absorbed. The Reform movement had by 1830 produced such a new theory, with a re-interpretation both of the ends and methods of popular government and civil society under a limited monarchy—but it was not until 1790 when Whiggism had been dissolved once and for all by the corrosive acids of the Industrial and French Revolutions that the school of Godwin, Priestley and Price, above all of Adam Smith and Bentham, had captured the best minds alike of the old gentry and the new individualists. In 1832 a true revolution was accomplished with less bloodshed and disturbance than "the glorious revolution" of 1688, and as in 1688 so in 1832, the monarchy entered on a new lease of life, influence and prestige.

The First Phase (1714-65).—In the Walpole and Bolingbroke era (1714-40) "reform" was the cry of the broken and discredited Tories or the schismatic Whigs, who denounced the corruption by which they asserted Walpole maintained his power, or who demanded the repeal of the Septennial Act and a return of the Triennial Act, or even to the annual parliaments of a "golden middle-age." The agitation, which had no support outside Westminster, had no effect on the general acquiescence in parliaments with a legal duration of seven years, and resulted only in a very limited Place bill, disfranchising a few hundreds of place-men. The elder Pitt gave a new life and a new power to the Reform movement, due to his prestige, his disinterestedness, the splendour of his achievements, and his criticism of effete or flabby government. But Pitt was neither a consistent political thinker nor a practical and constructive administrator, capable of creating and leading a party with a coherent and thought-out programme of internal reform. He accepted the Whig view that "representation was not of persons but of property," and that "the share of national burdens (*i.e.*, taxation of property) should decide the weight it

ought to have in the political balance." He accepted "the rotten boroughs" (for one of which he had sat) as "the natural infirmity of the Constitution." "Amputation might be death." Pitt's *sole* remedy for "the corruption of the people and the ambition of the Crown" was to add a third member to the county representation "the purest part of the system," and to revert to triennial parliaments. Neither of these remedies was seriously pressed, though they became a traditional formula for the Chathamite and Rockingham Whigs.

Cartwright, 1763-80.—John Wilkes, demagogue and the popular hero of the struggle against general warrants, for the right of the electors in the Middlesex election and for the right to report debates in parliament, with John Cartwright, the brother of the inventor of the power-loom, were, in 1776, the joint but independent "fathers" of the real Reform movement, *i.e.*, a demand not merely to eliminate the rotten elements, but by an extension of the franchise and a redistribution of seats to secure "a just and equal representation of the people." Wilkes and Cartwright pinned reform down to these points—disfranchisement, enfranchisement and redistribution—on the basis of two democratic principles, that government was for the good of the governed and that rich and poor alike had equal rights and an equal interest in determining laws and government affecting their lives, for times and happiness. The Reform Act of 1832 was thus fore-shadowed in embryo in 1776, the year of the Declaration of American Independence, of Adam Smith's *Wealth of Nations*, and Bentham's *Fragment on Government*. Cartwright, also, by founding *The Society of the Supporters of the Bill of Rights* was the parent of a new political method, the organized league for propaganda education and consolidation of a group with a defined and agreed programme. Radicalism, in short, as a theory of political life and a constructive political machine, was born in 1776. Cartwright's society was the fruitful mother of many leagues, societies and federations down to the Free Trade League of 1837, the "Birmingham Caucus" of 1878, and the party organizations of to-day.

The Whigs and Economic Reform.—The Whigs, under the influence of Dowdeswell and of Burke, would have none of either Wilkes' and Cartwright's principles, or of "demagogic" methods. The genius of Burke, reverencing the Constitution as almost a Divine gift to a chosen people, dreading organic change as the betrayal of a mighty heritage, and already, in 1780, scenting in the political theory of the American rebels and of the English Radicals the Jacobinical poison which the French Revolution was to let loose, saw in "economic reform" the supreme remedy for purging a sound organism afflicted by a temporary but paralyzing disease in the corrupting influence of the Crown. The Yorkshire Association and the famous Yorkshire Petition of 1780 were methods borrowed from the Radicals, but "the economic reform" for which they pressed kept clear of the Radical demand for organic reconstruction of the representative system. Burke and the Rockingham Whigs succeeded in disfranchising contractors and revenue officers, in abolishing sinecures and in reducing places and a swollen pension list, but in accomplishing this valuable result they had shot their bolt. They had not attempted to deal either with the legal disabilities which excluded whole classes from representation, or with the rotten boroughs which were far more demoralizing and far-reaching in their control of parliament than the "corrupt influence" of the Crown.

The Younger Pitt (1780-1785).—The mantle of Chatham fell, and the hopes of Radicalism concentrated on Chatham's son, the younger Pitt, who, in 1781, moved for "a Committee to enquire into the Present State of the Representation" and was defeated only by 20 votes—the best division the Reformers had between 1780 and 1832. As prime minister, in 1785, Pitt endeavoured to introduce a Reform bill, his intention being to disfranchise 36 rotten boroughs, establish a fund of £1,000,000 for compensating the owners of borough "property," and assign the 72 seats set free by the disfranchised 36 boroughs to the counties, London, Westminster and the chief unrepresented towns. "Leave to introduce" was, however, refused by a majority of 79 votes. Henceforward Pitt was lost to the Reform movement. It was his first and his

last effort as a constructive Reformer and the French Revolution shortly converted him into an obstinate antagonist to all or any change.

The Fourth Phase (1785-1807).—The movement really gained in the long run by this set-back. Had Pitt's milk-and-water proposals been carried the old system would have been given a new lease of existence. Pitt, equally with Burke, accepted the inherited past, and his acceptance of the rotten boroughs as a form of property, the disfranchisement of which required compensation, was rightly rejected as immoral and indefensible on any theory of national representation, by the Reformers of 1831. The Whigs had never really believed in reform, and it now became the monopoly of the "doctrinaire Radicals." For seven years the stars in their courses fought for Radicalism. The American War had given an immense stimulus to political thinking and a new school of political philosophy came into existence; the Industrial Revolution was steadily sapping the bases of 18th century society and of the economic fabric. In 1788 the centenary of 1688 was celebrated by the ardent Radicals and the young minds of the country outside politics. In 1789 the outbreak of the French Revolution galvanized all these currents into enthusiastic activity, and The London Revolution Society—the leading organization of the Reformers, of which Price and Godwin were vigorous members—entered into direct connection with the National Assembly in France and the Constitutional Revolutionists in Paris.

Fox, who hailed the French Revolution with joy, professed to be a Reformer, but he was in reality too deeply saturated with the old Whiggism to accept with conviction the new Radicalism. The real leaders in parliament were the young Charles Grey (the Earl Grey who carried the Reform Act in 1832) and Erskine. But all the ardent aspirations of 1789-92 were doomed to disastrous extinction, for which four main causes were responsible. First, the September massacres, the execution of Louis XVI. and Marie Antoinette, and the Reign of Terror not only paralyzed the moderate Reformers with a chill of disillusionment, but sent a series of waves of panic through Great Britain. Reform was promptly identified with revolution on the French model. Secondly, once Great Britain was at war with France (1793), reform was regarded as sedition and treason. Even the mildest critic of existing institutions was denounced as a Jacobin and a traitor. Thirdly, the opposition to reform found in Burke a thinker of genius whose "Reflections on the French Revolution" became the Bible, not only of Toryism, but of three-fourths of thinking or unthinking England. To Burke the new democratic philosophy of Price, Goodwin and Paine, even of Bentham and Mackintosh, was anathema, and the "Rights of Man" were exposed as the pseudo-scientific basis of a creed which would logically end in the downfall of the monarchy, a Jacobin Reign of Terror and a military dictatorship on the French model. The extremists on the Left of the Reform movement, with the bravado that extremists enjoy, were powerful allies of reaction. For 15 years Great Britain lived in the hurricane of a European convulsion, and Wyndham's phrase as to the folly "of repairing your house in the hurricane season," for all its shallowness, correctly summed up the mood of three-fourths of Great Britain, shown in the "loyalist" riots at Birmingham, Manchester and other industrial centres. Fourthly, the irreparable breach between Burke and Fox not only split the parliamentary opposition but drove one-half of the Whigs into coalition with Pitt and the Tory Party.

The war at first was popular; prosecutions for sedition followed, and the judiciary, especially in Scotland, where a great awakening of political activity had followed the French Revolution, were ready to strain the law of treason and to lay it down from the Bench that all criticism of existing institutions was calculated to bring the Government into contempt, and was, therefore, seditious treason. The proposal to hold at Edinburgh a British convention for the discussion of reform whetted the panic of the Government and the convention was dissolved. The trials and condemnation of "the Scottish martyrs" such as Tytler, Stewart, Callender, Muir, Palmer, Margaret, Gerald, Watt and Downie, and, in England, of Fend. Frost, Eaton and Winterbotham, make a soiled page in the history of British law. Thanks to

Erskine's splendid advocacy, the acquittal of Hardy and Horne Tooke brought some sanity into the supercharged atmosphere of indiscriminate terror and proscription. But until 1799 liberty of opinion ceased to exist in Great Britain, and in this valley of black shadows the numerous political societies, the chief of which were *The London Corresponding Society* and the *Society of United Scotsmen*, withered at the roots and were easily and finally suppressed by governmental action (1794-98). There would have been general and resentful astonishment could the memorial to "the Scottish Martyrs," on the Calton hill, at Edinburgh, erected by public subscription have been foreseen in 1800. Muir's "blasphemous" prediction that "the cause would ultimately prevail" was accepted as a platitude by a reformed and grateful Great Britain in 1844.

It "prevailed" for three reasons. First, the existing system of parliamentary representation provided its own condemnation when men could once more use their eyes, unblurred by panic and war-fever. Secondly, every five years of the changes made by "the Industrial Revolution" threw up a new and unrepresented population, creating a new wealth which paid three-fourths of the taxes but, under the old system, was not "property" with any political rights. Thirdly, the real Reformers retained their faith, and the new and abhorred creed of "democracy" was being hammered out by powerful minds, and could be proved to have a better scientific basis for the theory of a reborn, civilized and progressive society than the philosophy of Burke. To the England of 1807 and onwards the old Whig creed of 1688 was not to be regarded as a climax and a terminus, but simply a stage in an inexhaustible development.

The Fifth Phase (1807-1815).—A new point of departure was made in 1807. The Westminster election of that year brought Sir Francis Burdett, a wealthy and ardent Reformer, into the House of Commons to be the fearless and effective champion of the new Radicalism. The indefatigable Cartwright, who lived until 1824 and saw the dawn of the new day, was ready to join with Cobbett, "orator Hunt," Bentham, the stubborn and aristocratic Whig, Coke of Holkham, the "King of Norfolk," of whose respectability and place in the great gentry there could be no doubt. Reform had, in fact, its increasing adherents alike in the peerage, the intelligentsia and "the people." It only needed now two further acquisitions—the conversion of the official Whig Opposition and a first-rate organizer. The latter was found in Francis Place, the tailor of Charing Cross, whose career and gifts make a fascinating chapter in the history of British politics. Place, if any man, was the "organizer of victory." The conversion of the Whigs, led by Grey (who had succeeded to the earldom in 1807) was accomplished in 1820, when Lord Russell definitely associated the Whig party with the cause. Russell was ably supported by Brougham, and even more effectively by the aristocratic Radical, Lambton (later Lord Durham of the "Durham report"). Cartwright, in 1823, predicted that reform would "come suddenly." He did not live to see the passing of the Nonconformist Emancipation Act in 1828, of Roman Catholic emancipation by a Tory minister in 1829, or the triumphant passage of the Reform Act of 1832, nine years after his prediction. It was, indeed, in the irony of history that the French Revolution of 1789 should have shattered "the cause," and that a second revolution in France in 1830 should convert Great Britain to enthusiastic support of the Whig Reform bill of 1832.

BIBLIOGRAPHY.—The reform movement is treated in all the general histories and text books, notably by W. E. H. Lecky, *A History of England in the Eighteenth century* (1878-90; new ed., 7 vols., 1892). The best special books are: E. and A. G. Porritt, *The Unreformed House of Commons. Parliamentary Representation before 1832*, 2 vols. (1902); G. S. Veitch, *The Genesis of Parliamentary Reform* (1913); J. R. M. Butler, *The Passing of the Great Reform Bill* (1914). See also T. E. May, *Baron Farnborough, The Constitutional History of England since the Accession of George the Third; 1760-1860*, 2 vols. (1861; edit. and cont. to 1911 by F. Holland, 3 vols., 1912); W. R. Anson, *The Law and Customs of the Constitution*, vol. 1, "Parliament" (1886-91; 5th ed. by M. L. Gwyer, 1922). Of the numerous biographies, see particularly: G. Wallas, *The Life of Francis Place* (1918); and G. M. Trevelyan, *Lord Grey of the Reform Bill: being the life of Charles, second Earl Grey* (1920). (C. G. Ro.)

THE MOVEMENT IN FRANCE

If the political history of France be compared with that of England, it will be seen that the political system of both countries underwent similar changes, and arrived at approximately the same result—the main features of which were a responsible ministry and popular suffrage.

The political organization which was created both in France and in England was based on three essential elements: (1) an elected assembly capable of imposing an effective limitation on the power of the monarch; (2) a council of ministers subject to the control of the assembly; (3) an electorate capable of maintaining the control of the nation over the assembly. Three things were thus necessary in order to establish responsible government: the arbitrary power of the king must be restricted by an assembly independent of the court; the assembly must obtain effective control of the Government by transforming the king's ministers into agents for carrying out the will of the assembly; and the electoral system must be such as to ensure that the members of the assembly were representative of the will of the people.

In France the power of the king was so great that the people, who possessed no institutions through which they could exercise their action, were unable to impose any limitation on his authority. At a period when Great Britain already had a government responsible to an elected parliament, France had no political assembly, no franchise, and no check on the arbitrary power of ministers. The latter were simply the instruments through which the king exercised his personal authority.

It was impossible to modify this system, as had been done in England, by introducing successive improvements in the method of government, because there was no machinery in France through which control could be exercised. The change was made, without transition, by revolution; the old system of government was destroyed, and a new one had to be improvised. In devising a new system of government in this way it was of course necessary to proceed according to a general plan and to apply uniform rules of a legal and abstract character, whereas the British constitution was rather in the nature of a body of customs built up by a series of historical precedents. The difference in the method followed in the two countries has generally been attributed to a difference of national temperament, the Englishman being more phlegmatic, conservative and practical, and the Frenchman more passionate, revolutionary and fond of abstract ideas. It may however be more naturally explained by the different conditions under which the transformation of the political system was effected in the two countries. England already possessed an elected parliament which tended by gradual development to establish its control over the ministry; all that the English had to do was to reform their archaic electoral system. The French nation had to improvise an entire political system, and could only do so by the application of general rules.

The Revolution.—The French Revolution was initiated by the action of the royal Government itself in calling a meeting of the States General for the purpose of voting money. The meeting of the States General was not however, like the English parliament, an institution with the force of tradition behind it. The meeting called in 1789 under the old name of the States General was in reality a new assembly, summoned by a procedure created expressly for it.

Thus the question of the electoral system, which was the last to be settled in England, was in France the one which arose earliest. The system adopted was uniform for the whole country, and thus more logical than that of England. Voting was by secret ballot and by absolute majority. As the Government had extended the right to vote to all tax-payers, including the very numerous peasant class, the election of the deputies of the Third Estate was carried out by indirect suffrage. A system of indirect suffrage of two degrees, with a secret ballot and absolute majority, was applied to all elections of legislative bodies throughout the Revolution period.

The assembly, converted into a "National Assembly," declared that it would not separate until it had given France a Constitution; the royal power was thus limited by an elected body repre-

senting the nation as a whole. After the fall of Louis XVI. it became necessary to vest all powers in a single body, which was given the name of the Convention, a term borrowed from the United States. When the Convention desired to restore a regular political order conforming to the doctrine of the separation of powers, all that it could do was to replace the king by an executive Directory.

The third question, that of the qualifications and functions of ministers, had been settled under the pressure of practical necessities in 1789, when it had had to be decided whether ministers might also be members of the Assembly. The Constituent Assembly had been apprehensive of the influence which ministers might exercise over the legislative body; it feared the ambition of one of its members, Mirabeau. Ministers, as members of the executive, were therefore forbidden to be at the same time members of the Legislative Assembly; and this made it impossible to establish a system of responsible government in France.

The Restoration.—The institutions created by the Revolution were abolished by Napoleon, who reduced assemblies, elections and ministers to the position of instruments through which the absolute authority of the emperor was exercised. At the Restoration, however, a fresh attempt was made to create an organized political system. Louis XVIII. accepted the limitation of the royal power by a constitution and its control by an assembly. The three questions which had had to be considered in 1789 thus arose again in 1814; this time they were settled on lines directly copied from Great Britain.

Under the imperial regime there had been two chambers; Louis XVIII. maintained them under different names. The senate became a hereditary chamber of peers; the Legislative Assembly became the chamber of deputies, and the king had power to dissolve it, as in England. The chamber adopted a number of the practices of the British parliament, such as the King's speech, the voting of the Address, and the procedure for voting on ways and means.

The method of selecting ministers was not regulated by the Charter of 1814, just as there were no formal rules on the subject in England. Ministers were responsible, but only in the case of action contrary to the constitution, when they were liable to a procedure copied from the English system of impeachment. Thus France did not yet enjoy responsible government in the sense in which the term is understood in English-speaking countries at the present day. Louis XVIII. however generally followed the practice of forming the ministry in agreement with the majority of the chamber, and when Charles X., in 1829, appointed ministers who were definitely unpopular, the majority made an official protest, the "address of the 221," in which it enunciated the theory of responsible government.

The dispute led to an insurrection in Paris, and the Revolution of 1830 was the result. The new king, Louis Philippe, formally recognized the sovereign rights of the nation, and accordingly did not contest the principle of the responsibility of ministers to the Chamber. France thus adopted the principle of the political responsibility of ministers, according to which a minister is obliged to resign as soon as he is in disagreement with the Chamber.

"The Reform Movement."—The electoral system in France had been a constant subject of party-controversy from 1814 onwards. The practice of holding elections had been introduced as a new departure in 1789; it was not a long-standing tradition as it was in England, and it had not struck deep root in the political life of the nation. The Charter of 1814, which was hastily drafted, only contained a single provision dealing with the electoral system; no one was entitled to vote unless he paid not less than 300 francs in direct taxes. This represented a much more limited franchise than that in force in England, and the result was to deprive the elections of their popular character.

It was not until later that legislation was adopted fixing the minimum tax payment constituting the electoral qualification and the procedure for elections. The act of 1831, which was passed after the Revolution, merely lowered the electoral qualification from 300 to 200 francs. This resulted in increasing the number

of electors from 87,000 to 166,000; a maximum of 249,000 was reached in 1847.

One section of opinion in France regarded this reform as insufficient, since the large majority of citizens were still excluded from political life. Demands for the extension of the franchise were therefore put forward. At the time when in England the reform movement which had been initiated 60 years earlier was at last achieving success in the Reform Acts of 1832, agitation for the same object in France was only beginning. It is to the movement of 1832-48 that the term "reform" is applied in France.

Neither in France nor in England were the supporters of an extended franchise able to agree on the scope of the desired reform. Universal suffrage, which had been advocated in England as early as 1780, was not at first proposed in France except by a few isolated republicans. The *Société des Droits de l'Homme*, an association consisting mainly of young Parisian students and workmen, referred to universal suffrage in its manifesto of 1833 as an instrument for bringing about social revolution and improving the position of the proletariat; this attitude corresponded to that of the English Chartists.

The supporters of a less radical measure of reform put forward their demand for an extended franchise in the form of petitions to parliament, as had been done in England. The movement did not attain real political importance until 1838, when the National Guard of Paris, in which nearly the whole of the lower middle class population was enrolled, organized a petition asking that all members of the National Guard should be given the right to vote. A committee of deputies was formed to direct operations in the provinces; public manifestations were arranged, in which the National Guards marched in procession to greet the deputy with cries of "Vive la Réforme." The same cry was raised on June 14, 1840 at a review of the National Guard by Louis Philippe. The petition obtained about 340,000 signatures.

The opposition accused the Government of corrupting those deputies who were in the Government service by promises of promotion, and the electors by granting them personal favours. As a remedy for the "corruption" of deputies it demanded "parliamentary reform," i.e., that civil servants should be forbidden to sit in the chamber. As a remedy for "electoral corruption" it demanded "electoral reform." These were the terms which had been employed in England in the time of George III.

Universal suffrage was at no time demanded by more than a very small minority, much less numerous than the Chartists in England. Almost its only champion in the chamber was the lawyer Ledru-Rollin, who founded a journal entitled *La Réforme* in 1833. Ledru-Rollin represented political reform as a necessary condition for social reform. *La Réforme* did not however have a circulation of more than 2,000.

The campaign for reform was carried on in the chamber principally by the party which was opposed to the dynasty. For some years the question formed the subject of debates which led to no practical result. Guizot, the virtual head of the ministry, always replied that the introduction of reform measures was inexpedient. Louis Philippe himself took part in the dispute. "There will be no reform," he said in Jan. 1848; "I will not have it. If the Chamber of Deputies votes for it, I have the Chamber of Peers to reject it. Even if the Chamber of Peers adopted it, I have my veto."

The restrictions imposed on the press by the legislation of 1835 made it difficult for the opposition to state its views in the newspapers. A means of expression was found in the organization of a series of public dinners by opposition deputies and journalists; some 70 such dinners were held in 1847 and 1848, and toasts were drunk in honour of Reform. The Government, by prohibiting a public dinner in Paris, provoked the revolt which led to the Paris insurrection of Feb. 23 and the overthrow of the monarchy. The provisional Government, composed of deputies representing the small republican minority, at once introduced universal male suffrage. Thus electoral reform, which was only begun in England after half a century of agitation, was consummated in France in a few days in its most radical form.

française (1901), Eng. trans. B. Miall, *The French Revolution, a political history* (1910); *Histoire de la France contemporaine* (ed. E. Lavisse, vols. i. to v., 1902-22), with bibliography.

REFRACTION. When waves of any kind travelling in one medium enter another, in which their velocity is different, their direction is, in general, changed; the rays, i.e., the lines perpendicular to the wave surfaces (in isotropic media) along which the energy travels, being bent or refracted at their point of incidence on the second medium. The change in direction is such that the sine of the angle formed by the incident ray and the normal to the surface of separation bears the same ratio to the sine of the angle formed by the refracted ray and this normal as the velocity of the waves in the first medium to their velocity in the second. This ratio, known as the refractive index, may depend on the frequency of the wave vibrations. If such be the case, each frequency in the incident disturbance gives rise to a separate refracted ray—a phenomenon known as Dispersion. (See *LIGHT*.)

Mirage is due to the refraction of light by layers of air of gradually varying temperature and density. A similar variation, due to convection currents, is responsible for the flickering appearance seen, e.g., above asphalt and sand on a hot day, and also for the twinkling of the stars. (See *STAR*.) The refraction of rays of light entering the earth's atmosphere from heavenly bodies is known as Astronomical Refraction; it has the effect of making such bodies appear higher above the horizon than they really are. (See *ASTRONOMY: Spherical*.)

REFRACTOMETER, an optical instrument for the measurement of refractive index. The refractive index, n , of a substance is a property which depends on the velocity of light, V , within that substance relative to its velocity, V_m , in some other medium; $n = V_m/V$. Each pure substance has a unique value of n under standard conditions of temperature, pressure and wave length. In refractometry the measurement of light velocity is performed indirectly and relative to some standard medium, usually air or, in the case of gases, vacuum.

Historical.—Refractometers have occupied an important place in the chemical laboratory and in industry since 1874, when E. Abbe introduced the first instrument adapted to the routine investigation of liquids and solids. The Abbe refractometer was soon made commercially available by the C. Zeiss optical works. In 1887 C. Pulfrich brought out his refractometer for chemists, which had the advantage of allowing a precise and convenient measurement of the optical dispersion, an important property related to the change in refractive index accompanying a change in the wave length of the light. The Abbe and Pulfrich refractometers were based on the critical-angle principle of refraction, suggested in 1800 by P. S. Laplace as a means of determining accurately refractive index, and applied first by W. Wollaston in 1802. As early as 1856 an interference refractometer for determining small differences of refractive index had been devised by J. Jamin, who used the principles of light wave interference established earlier by T. Young (1801-04), A. J. Fresnel (1815-19) and D. F. J. Arago (1816-19). In 1896 Lord Rayleigh constructed an interferometer to study the behaviour of the newly discovered gas argon; the accuracy and convenience of his design stimulated further interest in the interferometric method. However, it was not until 1910 that this type of refractometer was generally applied; in that year F. Haber and F. Löwe made significant improvements and shortly thereafter practical models were placed on the market.

Prior to these developments of the late 19th century, refractometric measurements were performed with spectrometers or other devices originating in spectroscopy; these instruments were not well suited to the kinds of samples encountered in chemical investigations, and they required such careful manipulation as to discourage widespread use. The earliest work in refractometry goes back to the 17th century, when W. Snell established the basic law of refraction. Subsequently, on the occasion of his first scientific publication, Isaac Newton made a historic advance by showing that the refractive index depends on the colour (now interpreted as wave length) of the light used. Also, in Newton's

Opticks (1704) is to be found the first widely circulated publication of a table giving the refractive indexes of various fluids; he correlated these data with the densities of the substances and also noted some influence of chemical composition on the values of refractive index per unit density. An earlier table of refractive indexes compiled by Snell at Leyden was seen by only a few

cision refractometer considerably promoted this tendency. Even after the development of important physical tools for directly identifying molecular structures, such as spectrophotometry, the refractometer continued to occupy a prominent place. Its usefulness is primarily derived from the extreme sensitivity which can be attained and from the ease of manipulation. For example, differences in refractive index as small as 1 part per 1,000,000 can be determined with the ordinary interference refractometer; only a few minutes are required for filling the sample chambers and making the observations. This makes possible the detection of very small amounts of dissolved impurities.

Although the refractive index does not give direct information about the kind of molecular species present in a substance, refractometric studies of pure substances and of known mixtures have an importance for certain theoretical questions relating to chemical forces and molecular structure. The well-known ion deformation theory (1923-52), developed by K. Fajans and others, is based largely on refractometric data.

Optical Principles.—Refractometers generally fall into two broad classes, the deviation type and the interference type, each corresponding to an observable change in a light wave when it passes from one medium to another. These changes are connected with the difference of wave velocities in the two media and consist of: (1) a change in direction (unless the ray travels perpendicular to the boundary surface) and (2) a change in phase of vibration of the light wave. A third type of refractometer depends on the intensity of light reflected from the surface between two mediums, relative to the incident intensity. The principle of such a photometric refractometer was apparent ever since the derivation (*c.* 1830) of Fresnel's equations of reflection, but it was not until 1946 that a practical instrument was achieved. At that time the development of sensitive photoelectric cells had reached a stage which allowed the rapid detection of small changes in refractive index by the photometric method.

Basic to all deviation-type refractometers is Snell's law of refraction: $n = \sin i / \sin r$ (fig. 1). Snell's law means that the refractive index can be determined from the angle of incidence i and the angle of refraction r which the light ray makes with respect to a normal (*i.e.*, perpendicular) line passing through the boundary surface. The angles i and r are usually found indirectly from the observed deviations of a bundle of rays which traverse not only the sample but one or more prisms and lenses of the refractometer as well. In principle this method is reducible to measurements of the positions of pointers on a circular scale, corresponding to the directions of incident and refracted rays. In the spectrometer type of deviation instrument the incident rays come from a narrow slit so that, with a proper lens arrangement, the refracted rays can be located precisely. The spectrometer is ordinarily used with the principle of minimum deviation which states that a prism can be oriented to give a minimum angle, Δ , between incident and emergent rays (fig. 2); under these conditions, $i = e$ and the refractive index of the prism is $n = \sin \frac{1}{2}(\beta + \Delta) / \sin (\beta/2)$, where β is the angle between refracting faces of the prism.

Critical-angle refractometers make use of a more convenient method of locating the incident and refracted rays. The critical angle of refraction, C , is the maximum value of r which can be attained by any ray which passes from a less to a more refractive medium (fig. 3). In harmony with Snell's law, C corresponds to those incident rays which just graze the surface of the more refractive medium ($i = 90^\circ$). All other refracted rays come closer than C to the normal direction. In critical-angle refractometers a prism of known refractive index, n_p , is used as the more refractive medium. A beam of light is passed through the sample in a direction parallel to the boundary between sample and prism. On viewing the refracted rays through a telescope, there is observed a sharp critical boundary between a dark and a light region, shown in fig. 3, which very precisely defines the rays having the angles $i = 90^\circ$ and $r = C$. The refractive index of the sample is $n = \sin \alpha \cos \beta - \sin \beta \sqrt{n_p^2 - \sin^2 \alpha}$, where α (fig. 3) is the critical angle as modified by passage of the refracted rays from the prism into air and n_p is measured relative to air.

FIG. 1.—SNELL'S LAW OF REFRACTION. SUBSTANCE s HAS THE REFRACTIVE INDEX $n_s = \sin i / \sin r$, RELATIVE TO THE MEDIUM m , FOR LIGHT OF A GIVEN WAVE LENGTH λ . THE VALUE OF n_s IS A UNIQUE CHARACTERISTIC OF THE SUBSTANCE WHEN m AND s ARE MAINTAINED AT SOME STANDARD TEMPERATURE AND PRESSURE WHEN s = WATER AND m = AIR UNDER ORDINARY CONDITIONS, $n_s = 1.33$ FOR YELLOW SODIUM LIGHT ($\lambda = 5,893$ ANGSTROMS). IN THIS CASE, $r = 32^\circ$ FOR $i = 45^\circ$.

scientists, including Newton's great contemporary C. Huygens, before the manuscript was lost.

Uses.—Refractometers have found wide application as a rapid means of identifying substances and quantitatively analyzing solutions. In various industrial processes, such as petroleum refining and food canning, the concentrations of certain ingredients are kept within specified limits by means of refractometric analyses. For example, the sugar content of syrups is accurately controlled in this way. Many of the analytical problems continually arising in scientific research are solved by refractometric techniques.

Methods of analysis have shown an increasing tendency to depend on accurately measurable physical properties rather than chemical reactions and separations. The availability of the pre-

The interference-type refractometer depends on a set of interference bands, produced by the convergence of two light beams coming from the same slit source (fig. 4). If a transparent substance having a refractive index n is placed in the path of one such beam while the other beam traverses a comparable thickness of some other substance of index n_0 , there is a visible displacement of the interference bands. The interference refractometer allows a determination of the difference $n - n_0$ through measurement of this displacement.

The relationship between refractive index and band displacement can be understood by considering two converging wave fronts (fig. 4). If they come from the same slit source, there is a set of points for which the crest of one wave is exactly superimposed on that of the other; i.e., the waves are in phase and a maximum of light intensity exists at these points. At other points crests are superimposed on troughs, resulting in the complete absence of light. At still other points the relation between crests and troughs is intermediate. Thus, when the region of convergence of the waves is viewed through a lens, a series of alternately dark and light areas is seen; these constitute the interference bands. The bands usually appear as narrow vertical bars having fairly sharp edges. Consider now the change which takes place at the position, P , of the central bright band when one of the two waves is slowed down somewhat before reaching the region of convergence; i.e., when one wave is made to traverse a slightly more refractive medium than the other. In this case the crest of the retarded wave arrives at P too late to coincide exactly with the crest of the unretarded wave; the position of maximum intensity will have shifted to another point, O , such that both waves take the same amount of time to reach O . The distance between P and O is greater, the greater the difference in velocity of the two waves. On continuing to decrease the velocity of one wave—by interposing, for example, more and more of some gas having a greater refractive index than that traversed by the other wave—the region originally occupied by band P becomes darker and darker until the retardation corresponds to one-half wave length. For a retardation of one whole wave length this region becomes bright again, and so on. Under these conditions the bands appear to be moving continuously from the field of view. The magnitude of the band displacement is related to refractive index by the formula $n - n_0 = \lambda N/t$, where λ is the wave length of the light, t is the thickness of the interposed sample and N is the band displacement, expressed in number of band widths.

Usage, Construction and Performance of Instruments.—A number of variables must be carefully controlled in using precision refractometers. These are mainly temperature, wave length of light and alignment of parts. An increase in temperature of

curacy the highest quality workmanship is required in making the optical and mechanical alignments. Reliable refractometric measurements require frequent calibrations of the instrument with

FIG. 3.—CRITICAL ANGLE OF REFRACTION. RAYS HAVING AN ANGLE OF INCIDENCE OF EXACTLY 90° APPEAR IN THE VIEWING TELESCOPE AT THE SHARP BOUNDARY BETWEEN A LIGHT AND A DARK REGION, HENCE THEIR ANGLE OF REFRACTION CAN BE MEASURED ACCURATELY

known standards. The greatest accuracy is obtained when a direct comparison of the unknown with a similar known substance is made. The Pulfrich and the interference-type refractometers allow this kind of technique, known as the differential method. Easily purified liquids, such as water, serve as convenient standards of comparison; glass test plates are also used. In 1944 the U.S. national bureau of standards made available a series of pure hydrocarbons with refractive indexes certified to the fifth decimal.

A variety of refractometers has been made commercially available by optical manufacturers in Europe and the United States; in addition, many others have been constructed in laboratories and described in detail in the scientific literature. Of the types on the market, the critical-angle principle is the most widely used.

The Abbe refractometer (fig. 5) is perhaps the most popular critical-angle instrument. The ordinary model is rugged, compact (about the size of a microscope) and is capable of fourth-decimal accuracy. Only a few drops of liquid sample are required, and a determination may be completed in less than five minutes. Liquid samples are confined to a thin film between the surfaces of the refracting prism P ($\beta = 60^\circ$) and an adjacent auxiliary prism P' . The latter prism also serves as a window; its roughened surface scatters into the sample some light along the direction of grazing incidence, required for the critical boundary. For convenience white light can be used but in this case the critical boundary is not inherently sharp and has the appearance of a rainbow because of the different refraction for rays of different wave length. Most Abbe models are provided with a pair of compensating prisms, mounted in the barrel of the telescope, which remove nearly all the boundary colour and improve the accuracy. The amount of rotation of one compensating prism relative to the other, required for achromatizing the boundary, is a rough measure of the dispersion of the sample. The compensating system is designed to give refractive indexes corresponding to an average wave length near that of the yellow sodium lines. The refracting prism, located at the base, can be rotated with respect to the telescope axis (see point R , fig. 5). With an illuminated solid or liquid sample on the lower face of this prism, the critical boundary can be made to coincide with the cross hairs in the telescope, using a

FIG. 2.—PRINCIPLE OF MINIMUM DEVIATION, USED WITH SPECTROMETER TO DETERMINE REFRACTIVE INDEX n OF PRISM: $n = \sin [(\beta + \Delta)/2] / \sin (\beta/2)$

1° C. causes, for most liquids, a decrease in n of several units in the fourth decimal. The refractive index of a colourless substance measured with red light may be as much as several units in the second decimal smaller than when measured with violet light. The most widely used monochromatic light source is the sodium lamp; unless otherwise stated, values of n refer to the average wave length of the yellow sodium spectral lines (5,893 angstroms). Electric discharge tubes containing elements such as helium, hydrogen, cadmium or mercury provide a series of well-defined wave lengths, useful for determining the optical dispersion.

For instruments designed to give fourth- or fifth-decimal ac-

FIG. 4.—PRINCIPLE OF THE INTERFERENCE REFRACTOMETER. THE AMOUNT OF THE DISPLACEMENT OF THE BANDS (DISTANCE $P-Q$) CAUSED BY SUBSTITUTING MEDIUM n FOR n_0 IN THE PATH OF ONE WAVE IS PROPORTIONAL TO THE REFRACTIVE INDEX DIFFERENCE $n-n_0$

slow-motion screw to rotate the prism. A pointer attached to an arm (alidade) of the prism-mount indicates the degree of rotation on a goniometer scale attached to the telescope. The scale reads directly in terms of refractive index or, as desired, in terms of concentration of some solute. Each instrument is limited to a given range, depending on the glass of the prism. Usually values of n from 1.3 to 1.7 can be covered.

The *Pulfrich refractometer* is a versatile critical-angle instrument especially useful in measuring small differences in refractive indexes, particularly at various wave lengths of light (dispersion). The solid or liquid sample is placed on the horizontal surface of the refracting prism ($\beta = 90^\circ$), as in fig. 3, and illuminated by focusing light at grazing incidence. Light sources which give spectral lines are employed. There is a separate critical boundary for each wave length in the source; these are distinguishable unless the sample and the prism have the same optical dispersion. To locate the critical boundary, the prism is kept in a fixed position while the telescope is moved about the circumference of a graduated circle. The angular position of the critical boundary is read from a vernier on the circle; the corresponding value of n may be calculated or found from tables. The difference in angular position of two fairly close critical boundaries is measured with a graduated micrometer screw which moves the telescope. In this way the differences in refractive index for various wave lengths are found with fifth-decimal accuracy.

The *dipping or immersion refractometer* resembles the Abbe instrument. The refracting prism, compensating prisms and telescope are mounted in a single tube, giving a compact, portable unit. The prism is directly immersed in liquid samples and the critical boundary is located with respect to a movable eyepiece scale. The dipping refractometer is ordinarily used by making a calibration of scale readings vs. concentration of some solute. The accuracy is only slightly better than that of the Abbe, but it has the advantage of a greater range through interchangeability of prisms.

Deviation-type instruments which do not use the critical-angle principle have certain important advantages. For example, *spectrometers* cover an unlimited range of refractive indexes and, when properly equipped, can be used with ultra-violet or infra-red light. An accurately shaped prism mounted at the centre of a movable graduated circle constitutes the basic element of the spectrometer. The prism consists of, or contains, the sample under investigation. Monochromatic or polychromatic light from a narrow slit source is rendered parallel by a collimating lens before traversing the prism. For each wave length an image of the refracted light source is located by means of a telescope mounted on the circle. The many necessary careful adjustments make the spectrometer inconvenient for routine applications. However, its principle is employed in a number of simple *image-displacement refractometers*. These may be designed for rapid measurement of very small quantities of liquid samples with third-decimal accuracy. The sample is made into a tiny prism by placing a droplet between

an appropriate set of glass surfaces. If an illuminated object, say a slit, is viewed through such a prism, its apparent position is shifted from the true position by an amount which depends on the refractive index of the sample and of the glass. The amount of image displacement can be observed on a scale mounted behind the prism; the scale is usually calibrated in terms of n . A convenient application of this principle is found in the *Nichols refractometer*, which uses a microscope for observing the image displacement. The ordinary microscope itself is capable of being used as a simple refractometer of this type.

Interference refractometers are indispensable for finding the refractive indexes of gases; they can also be used for liquids and some solids. The interferometric method offers the most convenient means of determining the concentration of a substance in an extremely dilute solution. Differences in refractive index as small as 1 part per 1,000,000 can be detected without elaborate precautions and still higher sensitivities have been achieved. Even such small differences may be of practical importance, as in the industrial analysis of air. Portable interference refractometers have been used to detect traces (0.1%) of methane (marsh gas) in coal mine air as a means of preventing explosions.

The basic elements of the *Rayleigh interference refractometer* (fig. 7) are two achromatic lenses of long focal length, the first for rendering parallel the light from a narrow slit source, the second for bringing about convergence of two beams, B_1 and B_2 , emerging from two broad slits in front of the first lens. The in-

FIG. 5.—ABBE REFRACTOMETER (SCHEMATIC)

interference bands are generally viewed with a cylindrical lens focused on the focal plane of the second achromatic lens. Cells C_1 and C_2 for the reference substance and the sample are placed side by side, each in the path of one emergent beam (B_1, B_2).

Commercial instruments are usually of the "Rayleigh-Haber-Löwe type" (fig. 7), which uses the convenient Jamin method of obtaining the band displacement. An actual count of the bands which traverse the field of view is not necessary; instead, a sufficient thickness of glass, P_1 , is interposed in one beam to just equal the retardation caused by the sample in the other beam. The greater the compensating thickness required, the greater the value of $n - n_0$. In fig. 7 the effective thickness of P_1 is adjusted by means of the tilting lever L and micrometer screw M . The condition of exact compensation is determined, using white light, by turning the micrometer screw M until the central band is brought back to the position it had before the sample was introduced. The central band can be recognized because it is the only one having a pure white colour. Its position is located by matching with a fixed auxiliary set of interference bands formed by two reference beams, b_1 and b_2 . The reference beams traverse equivalent paths of glass and air so that instrument distortions shift both bands in the same way and errors of alignment are minimized. The prism Pr in fig. 7 serves to bring the two sets of bands closer together for ease of comparison. Improved interference refractometers have achieved a sensitivity of one in the eighth decimal, corresponding to the effect of adding one milligram of salt to a litre of water. Such accuracy involves the use of monochromatic light, which, however, allows no visible distinction to be made between the central band and the others. This difficulty has been overcome in several ways, the most reliable being based on the rotating chamber device developed by W. Geffcken. In this apparatus the two sample cells are rotated with respect to the beam direction while a count is made of the number of bands traversing the field of view. There is a known relation between refractive index and the number of bands for a given angle of rotation.

Modern trends in interference refractometry show a revival of interest in the early instrument of Jamin, as modified by E. Mach and L. Zehnder (1891). Certain technical drawbacks were overcome by H. Kuhn and G. A. Wheatley in 1945. Outstanding contributions to aerodynamics have been made by using the Jamin-type interference refractometer to study local variations in the density of air flowing at high speed past solid surfaces.

Automatic recording refractometers are in the early stages of development and show promise of widespread application in science and industry as a means of rapidly detecting or controlling small changes in flowing liquids or gases. Any of the three types of refractometers

may be adapted to automatic recording by substitution of a photoelectric cell for the human eye, since the electric current produced by such a cell is a measure of the intensity of light falling on the cell at a precisely known location.

(No. Br.)

REFRIGERATION AND ITS APPLICATION. Refrigeration is understood to mean the process of securing a temperature below that of the atmosphere by the use of some mechanical device. It has three main divisions: cold storage and food preservation (packing plants, etc.), ice making and air conditioning and cooling. The extent of these applications is increasing rapidly, and, in addition, special processes requiring refrigeration—as in the chemical industries—are being developed so that refrigeration is becoming increasingly important.

THEORY OF REFRIGERATION

The most general method of securing mechanical refrigeration is to use a reversed heat engine whereby heat is absorbed at the lower temperature and is rejected at the upper temperature with a direct acting engine or an electric motor providing the external work required to make the cycle possible. If the Carnot heat cycle (see INTERNAL COMBUSTION ENGINES) is used for the production of power, the reversed Carnot cycle is the one employed in the refrigerating cycle. Such a reversed cycle cannot have a greater efficiency than the direct cycle.

According to the second law of thermodynamics (*q.v.*) the efficiency of the cycle is independent of the kind of working medium used, and is dependent only on the temperature limits. If it were possible to operate according to the Carnot cycle one could, in principle, produce a perfect refrigerator. In practice, however, the efficiency of a refrigerator is always less than that of a Carnot refrigerator operating between the same temperature limits.

Heat Cycles.

The *p-v* diagram is the simplest and most useful diagram for representing the refrigerating cycle. The value of h is given by the expression $h = U + Apv$, where U is the energy, p the pressure, v the volume, $A = 14.7 \times 778$; therefore $dh = du + A p dv + v dp$, but $dq = du + A p dv$; therefore $dh = dq + v dp$, so that for a constant pressure process $dh = dq$ or $h_1 - h_2 = \int_1^2 Q_2$. From the last equation it is clear that in a constant pressure process the heat absorbed is equal to the difference in the value of h at the beginning and the end of the process.

The Refrigerating Cycle.—In refrigeration the volatile liquid is permitted to pass into evaporating coils under reduced pressure and there it boils, absorbing heat from the commodities to be

FIG. 6.—ABBE REFRACTOMETER

BY COURTESY OF BAUSCH & LOMB OPTICAL CO.

cooled. The liquid at the condenser pressure is indicated by the point *a* in fig. 1 and the line *ab* is the drop of pressure in the pressure-reducing (the so-called expansion) valve. Such a throttling process is one of constant *h* and is shown by the equation for steady flow. If an expansion cylinder had been used, the light line *ac* would have indicated the process and this being reversible in the thermodynamic sense, the cycle would be more

FIG. 1.

efficient than the one having the expansion valve. The point *b* represents the condition of the working medium with the reduced pressure, and with the temperature corresponding to the pressure obtainable from suitable thermodynamic tables. Fig. 1 shows that the point *b* corresponds to a point having 16% vapour, or (in other words) 16% of the liquid is evaporated in cooling the liquid refrigerant from the temperature at *a* to that at *b*.

Useful refrigeration is shown by the evaporation line *bc*, during which time the heat absorbed by the refrigerant per pound is $h_a - h_b = h_c - h_a$. The point *c* represents the gas leaving the evaporator coils and entering the compressor. The compressor process is shown by the line *cd* and the work of compression per one pound of the refrigerant is given by the value of $h_d - h_c$. Finally the constant pressure line *da* represents the heat lost by the compressed gas first in the removal of the superheat *df* and then the latent heat of liquefaction *fa*. The heat absorbed by the condensing water per one pound of the refrigerant is $h_d - h_a$.

As stated, the useful refrigeration per pound of refrigerant is given by the expression $h_c - h_a$. In the United States the ton of refrigeration is defined as the absorption of 200 B.T.U. per minute. The ton of refrigeration in Great Britain is given as the absorption of one kilogram calorie per second which is larger than the United States unit by 18.8%. Using the United States definition the piston displacement per ton of refrigerant per minute theoretically is

$$\frac{200}{h_c - h_a} (v_g)_s \quad \text{where } (v_g)_s \text{ is the volume of 1 lb. of dry, saturated refrigerant at the pressure } p_1.$$

Allowance, however, must be made for the volumetric efficiency which may be as small as 50% or less under extreme conditions.

This is a factor to account for the superheat in the suction gas occasioned by the absorption of heat from the cylinder walls, piston head, etc. An idea of the extent of this loss can be seen in Table I.

The preceding equation can be corrected for volumetric efficiency as follows.

$$\frac{200}{h_c - h_a} (v_g)_s \quad \text{where } E_v = \text{the volumetric efficiency due to the effect of the cylinder walls, etc.}$$

$E_c = \text{volumetric efficiency due to clearance.}$

The work done by compression, per ton of refrigeration, is

$$\frac{n}{n-1} p_1 (v_g)_s \left[1 - \left(\frac{p_2}{p_1} \right)^{\frac{n-1}{n}} \right] \quad \text{where } n = 1.28 \text{ for ammonia and carbon dioxide, } p_1 \text{ is the suction pressure in lb. per sq. ft. and } (v_g)_s \text{ is the volume of 1 lb. of dry saturated vapour at the pressure } p_1.$$

Also referring to the figure the value $h_d - h_a$ = the work performed in the entire cycle in compressing the pound of gas. The work of compression, per ton of refrigeration, is also

$$\frac{200}{h_c - h_a} \frac{h_d - h_a}{h_c - h_a} \quad \text{B.T.U. per minute} = 4.73 \frac{h_d - h_a}{h_c - h_a} \text{ h.p.}$$

The formula for the work of compression and horse-power should

be increased by an amount $\frac{1}{E_v}$ to account for the effect of volumetric efficiency. Clearance has been found to have little effect on the h. p. and is usually neglected in power calculations.

TABLE I. Horse-power per Ton of Refrigeration (Ammonia)

Condenser pressure lb. gauge	Suction pressure lb. gauge					
	5	10	15	20	25	30

200	A	0.71	0.77	0.81	0.84	0.86
	B	0.49	0.61	0.68	0.72	0.75
	C	0.37	0.52	0.62	0.67	0.71

A, No clearance. B, 4% clearance. C, 6% clearance.

The water required for condensing purposes may be calculated as follows:

The heat absorbed theoretically by the condensing water per ton of refrigeration per minute is

$$\frac{200}{h_a - h_a} (h_d - h_a) = 200 \frac{h_d - h_a}{h_c - h_a}$$

and allowing for volumetric efficiency, this formula becomes

$$\frac{200}{E_v} \frac{h_d - h_a}{h_c - h_a}$$

If the water rises in temperature 10° F., then the number of gallons of condensing water will be per ton of refrigeration, per minute,

$$\frac{200}{8.33 \times 10 \times E_v} \left(\frac{h_d - h_a}{h_c - h_a} \right) \quad \text{where 1 gal. weighs 8.33 pounds.}$$

REFRIGERANTS

Liquids Used in Refrigerating Machines.—Modern mechanical refrigeration (as well as other heat cycles) has undergone a great change during the last decade or two. The improved automatic refrigerating machine and the advance in the use of comfort cooling have emphasized the need of a refrigerant that will be non-toxic and non-inflammable. In Table IIa, column 10, the coefficient of performance is reasonably the same for all refrigerants of the volatile liquid type when the temperature of liquefaction is not too near the critical and where the properties of the refrigerant are well known, for example, "F-12" ($\text{C}_2\text{Cl}_2\text{F}_2$) whose evaporating pressure is given in the table as 26-slb. per sq.in. abs., compared with Carrene ($\text{C}_2\text{H}_2\text{Cl}_2$) where the pressure at the same evaporating temperature is only 1.17-lb. per sq.in. abs., and the piston displacement per ton of refrigeration 5.8-ft.³ per minute for "F-12" and 76-ft.³ per minute for Carrene. The large volumes required for Carrene, "F-12" at low evaporating temperatures, dieline ($\text{C}_2\text{H}_2\text{Cl}_2$) and water vapour for comfort cooling can be handled satisfactorily by means of the centrifugal compressor where the refrigerant may be compressed efficiently by careful design of the compressors so as to reduce friction in the impellers and diffusers. When the evaporating pressure is below atmospheric, as in the case of Carrene, dieline, ethyl chloride, sulphur dioxide, water vapour and butane (C_4H_{10}), air leaks are likely to be excessive, although where the refrigerant is nearly odourless ("F-12" and methyl chloride) leaks into the atmosphere, and loss of the refrigerant, may be excessive also.

Ammonia is used, and undoubtedly will continue to be used, extensively in the United States for commercial work, where in 1938 the Freon refrigerants had been adopted by only 15% of the new compressors of 26-100 tons cap. and only 2% of those over 100 tons. Ammonia is dangerous to animal life, and corrodes copper and copper compositions. It has a large value for the latent heat of vaporization, its unit pressures and specific volumes are nominal and it is not miscible to any large extent in the usual mineral oils. Leaks are easily detected by means of the use of sulphur dioxide vapour. Carbon dioxide has been used as a safety refrigerant for a long time, as its presence in the confined space of a ship's hold, even in large per cent by volume, is not a serious hazard unless the exposure is prolonged. Its condensing pressure is excessive for condenser water initially at 70° F. and higher, and with cooling water of about 80° F. it will not condense, so that with liquefaction near the critical temperature of about 87.8° F. the efficiency (coefficient of performance) is low (see Table IIa). The triple point is -69.9° F. Sulphur dioxide is used almost entirely in fractional tonnage machines in which it lends itself to the air-cooled condenser. It is not inflammable, but is an irritant and a toxic gas, in spite of which it is practically harmless in the small household refrigerating machine. However, it is dangerous in multiple systems. Unless sulphur dioxide is anhydrous it will corrode the common metals used in the construction of pressure vessels. Methyl chloride,

an anaesthetic in amounts of 5 to 10% by volume, may be used in air-cooled condensers and is successful in both large and small-sized units. It is miscible in mineral oils, and water in the system will freeze in the expansion valve. Leaks may be detected

TABLE IIb Comparison of Losses, When Using the Usual Refrigerants with the Ideal Carnot Cycle (The usual cycle for volatile liquid refrigerants is shown by the cycle abcdA [fig. 1]. Losses are due to throttling (process ef) and compression from m, d, o, d.

Note the small loss in the latter case for "Freon 12" (CCl_2F_2).

Refrigerant	Work of compression for the Carnot cycle (area abcd) in B.T.U. per lb. of refrigerant		Theoretical work of compression (area efgh) in B.T.U. per lb. of refrigerant		Loss due to throttling process (area efgh) in B.T.U. per lb. of refrigerant		Throttling loss in per cent of work of Carnot cycle (area efgh) × 100		Excess work of compression (area efgh) - area abcd		Excess work of compression (area efgh) - area abcd		Excess work of compression (area efgh) - area abcd		Total losses, in per cent of the Carnot cycle	
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Ammonia (NH_3)	8.06	9.67	7.7	9.16	7.8	9.08	18.45									
Sulphur dioxide (SO_2)	24.97	29.07	1.84	3.69	2.6	9.08	16.45									
Methyl chloride (CH_3Cl)	26.61	30.66	2.41	9.09	1.62	6.00	15.18									
Dichlorodifluoromethane ($\text{C}_2\text{Cl}_2\text{F}_2$)	9.19	10.85	0.61	17.53	0.05	0.54	18.06

by the use of acrolein. Dichlorodifluoromethane ("F-12") is taking the place of both ammonia and carbon dioxide, especially where the public is exposed seriously to the effect of heavy leaks. "Freon-12" is almost an ideal refrigerant inasmuch as it is not toxic, inflammable or irritant. The air-cooled condenser may be used, and leaks can be detected with a special torch. Ethyl chloride has as yet been used but little as a refrigerant, and the same is true of the hydrocarbons butane and propane. The use of dichloroethylene ($\text{C}_2\text{H}_2\text{Cl}_2$) and methylene chloride (CH_2Cl_2) have been confined to the centrifugal compressors. Very low temperature refrigeration may use ethane, ammonia, or dichlorodifluoromethane. Other halides such as "F-11" (CCl_3F), "F-21" ($\text{CH}_2\text{Cl}_2\text{F}$) and "F-114" ($\text{C}_2\text{Cl}_2\text{F}_2$) may be generally used to a greater extent in the future.

The Reciprocating Compressor.—Modern mechanical refrigerating machines are radically different from those of a few decades ago. Modern design calls for mass production, especially in the smaller sizes. The large capacities, slow revolution, long stroke machines, steam engine driven, have been replaced by electric motors, frequently of the synchronous type direct connected to the compressor, with the compressors designed for rotational speeds up to 400 revolutions per minute. The enclosed type of compressor, of the single-acting, vertical design, is almost universally used, with 3, 4, and even 4 cylinders, the latter up to 80 tons of refrigeration, on the same crank-shaft. The stroke is very short, frequently with the piston diameter 50% greater than the stroke. Mechanically operated valves are rare, and they are usually of the ring plate type design, made of chrome-

TABLE IIa Comparison of the More Common Volatile Liquid Refrigerants (Note the low value of the coefficient of performance for CO_2)

Refrigerant	Critical temperature (°F.)		Critical pressure (lb. per sq.in.)		Average value of $\frac{h_g - h_f}{t_g - t_f}$		Theoretical specific work (B.T.U. per lb.)		Theoretical coefficient of performance		Evaporating pressure (lb. per sq.in. abs.)		Liquefaction pressure (lb. per sq.in. abs.)

*In lb. of mercury.

dium steel, hardened ground to a true surface; however, the light-weight, spring-balanced cushioned poppet valve is still used. Lubrication is forced to every bearing, and the oil pump section is equipped with filters. Methyl chloride and dichlorodifluoromethane as well as methylene chloride, are miscible in the usual mineral oils used in refrigeration, thereby making a special design, necessary to separate the oil from the return suction gas. This is accomplished in the refrigerating compressor by a special trap in

the manifold of the compressor. The pistons are supplied with oil rings, to prevent oil pumping, as well as the usual compression rings. In particular, the use of automatic devices, making efficient operation possible with the minimum of manual control, has materially changed the design, the operating details of the refrigeration unit. The use of the halide group of refrigerants, especially dichlorodifluoromethane as well as methyl chloride has made possible the air-cooled compressor using fins on the cylinders, and a considerably lighter construction of the compressor. When water-jacketed cylinders are employed, as with ammonia compressors, the jacket is confined to the neighbourhood of the head. With high rotative speeds the effect of the jacket water on the amount of superheat in the compressed vapour at the end of the compression stroke is not very great, but when used in the water in the jacket is expected to keep the lubricating oil reasonably effective.

Little attention is paid to clearance in the cylinder although at one time the clearance volume in per cent of the piston displacement was reduced to a minimum. Clearance is considered to act as a compressed spring and to have little effect except to reduce the effective pumping capacity of the refrigerant, and control of the refrigerating capacity for constant speed operation is obtained by the use of clearance pockets under the control of the operator or by passing part of the vapour to be compressed to the suction side of the compressor. A type of modern (1938) compressor can be used as a booster compressor. If designed for this purpose it would be of relatively large piston displacement, short stroke and of light construction. It would handle the low pressure stage of the load and as the suction vapour temperature would be quite low, the use of the water jacket would be dispensed with even for ammonia.

The Absorption Machine was more important about 1913 than in 1939. This refrigeration machine requires the direct application of heat instead of mechanical work in order to increase the pressure of the gas to a point where liquefaction may occur in the condenser. The heat necessary for this action may be due to the burning of gas or it may be obtained from high pressure or exhaust steam. In the United States the absorption machine is used where exhaust steam is plentifully available and also in the small, fractional-tonnage units.

The principle of the action of the absorption machine is that a solution of ammonia and water is used in a still or generator where heat is applied. The action of the heat is to drive out some of the gas from the solution under a pressure corresponding to the condenser pressure, and the gas is condensed, in the condenser, and passes to the evaporator in the same manner as is the case in the compressor system. However, the gas from the evaporator has to be returned as a solution, or strong aqua, to the generator. This is done by sending the weak aqua, which is at the lower part of the generator, to the absorber having cooled it previously, and there bringing it into intimate contact with the gas from the evaporator. The resulting strong aqua occupies very little volume in comparison with that of the gas from the evaporating coils, and may be pumped by means of a strong aqua pump into the generator.

The advantages of the absorption machine are the use of exhaust steam at very low cost. It is used in the United States in packing plants, oil refineries and in some hotels where a combination of the steam-driven compressor and the absorption machine works out economically at times. The absorption machine will also take a low temperature of evaporation without difficulty because the volume of the strong aqua from the absorber is not affected by the evaporator pressure in any way. However, these advantages had lost their importance by 1928 because of the economical advantage of stage compression.

The Intermittent Absorption Machine.—The absorption machine described above has one moving part, the so-called strong aqua pump. In order to eliminate all moving parts the machine may be modified in such a way that it then will operate intermittently. In the intermittent absorption machine the still or generator is also used as an absorber. During the period when heat is applied to the generator the ammonia gas is distilled off to the condenser to be condensed and finally stored in a liquid receiver. When the required amount of liquid has been accumulated the steam or gas is shut off

from the generator, cooling water is turned on and the expansion valve opens. As liquid passes into the evaporating coils refrigeration is accomplished and the gas proceeds to the generator now acting as an absorber, and is kept cool by the water-cooling coils. The intermittent absorption machine has less surface than the regular absorption machine as it eliminates the absorber, the exchanger and the weak aqua cooler as well as the strong aqua pump. It cannot, however, give continuous refrigeration. The machine operates automatically.

The Platen-Munters Absorption Machine.—This is another type of machine built to eliminate the strong aqua pump. The outstanding features are the elimination of the expansion valve by a device whereby the pressure in the system is made constant throughout the cycle, and the addition of a charge of an inert gas, usually hydrogen, in the evaporating coils and the absorber. As the pressure in the absorber and the generator is the same, a force sufficient to overcome only the frictional resistance of the pump is required. This

have been developed, one of which is silica gel. Such adsorbents are solid materials composed of a large number of minute air cells, capable of adsorbing sulphur dioxide as well as water vapour.

Fittings.—The working medium, or refrigerant, is contained in refrigeration in a closed system and is used continuously. It is dear enough to make it desirable to keep leaks down to the lowest point possible and, with ammonia, dangerous enough so that excessive leaks are to be carefully avoided. The result is that the design of the system has the prevention of even nominal leaks as a first consideration. In consequence the pipe fittings are made specially strong, and are either of dense, air furnace, cast iron or are drop forgings. The screw joint is made up with litharge and glycerine or a soldered joint is made up by tinning the screw threads. With drop forgings the fitting may be welded to the pipe, and this has been found especially advantageous in the case of carbonic systems.

The piping may be either steel or wrought iron and usually of standard weight. The pipe is usually lap-welded in sizes 2 in. or over and butt-welded in smaller sizes.

Condensers.—Design has undergone considerable advancement since 1918. At first, safety dictated the use of pipe condensers, arranged in stands of 30 or more pipes high and with pipes 20 ft. long, but the height of the stands has been gradually decreased until now the usual number is 12 pipes. In these pipe condensers, the gas from the compressor enters at one end of the condenser, and the refrigerant is condensed during its passage through the 200 or more feet of pipe composing the condenser. Attempts to achieve counter-flow of the ammonia and the condensing water and more control in the velocity of the water have resulted in the following types of condensers: the submerged, the common atmospheric, the double pipe and the flooded designs. The more recent designs are the shell and tube single-pass and the shell and tube multi-pass condensers. In the multi-pass type the water fills the tube whereas in the vertical shell and tube condenser the water is made to flow as a film on the inside of the tubes.

Research on heat transfer in ammonia condensers has developed so that there is no advantage in the counter-flow principle, whereas it is highly desirable to remove the liquid condensate as quickly as possible from the condensing surfaces. It has been found impossible to subcool the liquid unless the liquid is free of its own vapour and so the elaborate attempts to achieve the counter-flow arrangement are not worth the trouble. On the other hand, the ordinary condenser has 50% of all liquefaction occurring in a small portion of the condenser where the condensing water enters the condenser. This part of the condenser is the upper 3 ft. of the shell and tube and the lower two pipes of the double pipe condenser.

Use of Brine: Direct Expansion.—There does not appear to be any definite rule in regard to the use of brine or direct expansion. The use of direct expansion means a lower cost of

operation inasmuch as the suction pressure required will be less when cooling brine in order that the latter may be used to cool air, or other substances to be refrigerated than when the evaporating coils are used directly for the desired cooling. Such a double cooling means that more horse-power per ton of useful refrigeration is required than with direct expansion. However, brine makes it possible to have considerable flexibility and more safety. A brine spray may be used for cooling air, or brine storage may be utilized for the purpose of storing up refrigeration to be used to carry the load during a "peak" or during the intermittent operation of the refrigerating machine. The meat-packing organizations use brine in the majority of cases, whereas cold storage plants frequently use direct expansion if the system is self contained. District cooling plants, as found in certain localities in large cities, prefer brine because of the reduced danger due to leaks, loss of refrigerant and excessive pressure drop in the long suction lines.

The kind of brine is confined to calcium and sodium chloride, and the former is used where temperatures of 10° F or lower are required, because of the ability of calcium chloride to take low temperatures without freezing. The corrosive action of brine with respect to metals is a very moot point. As a rule there is little tendency for "corrosion" if the brine has a specific gravity of 1.2 and is kept neutral or slightly alkaline. The use of mixtures of several salts is very unwise as this tends to corrosion. It has been found also that any brine which is unstable in character and tends to become acid will be bound to cause excessive "corrosion." The best means of preventing corrosion in the open or closed brine systems is to use sodium dichromate in sufficient quantities to make the brine slightly alkaline. Zinc dust may be used to advantage in open calcium chloride brine circuits.

The Automatic Refrigerating Machine.—The small refrigerating machine has to be automatic in every sense of the word. In order to do this the machine must be thermostatically controlled so as to start and stop with a slight change of the temperature of the commodity to be refrigerated. The automatic controls which are required in order to have a successful automatic refrigerating machine of the compressor type are: (1) a suitable thermostat, (2) a means of controlling the evaporating pressure, (3) a condensing water control, if the water cooled condenser is used, (4) an excess pressure shut-off.

The thermostat (*g.v.*) is usually of the metallic coil or the volatile liquid bulb and bellows type. In either case a change of temperature causes a motion of a contact point or of the arm of a lever sufficient to cause the make or break of an electric circuit. The latter may be direct on the motor line or it may operate a relay switch. The evaporating pressure is controlled either by means of a float valve, operated either on the condenser pressure or the suction pressure side of the system or by means of a pressure reducing (expansion) valve. The expansion valve is of the needle valve principle, using a spring loaded diaphragm. Variation of the suction pressure may be obtained by a manual control of the tension of the spring. The water pressure control may be from the principle of the temperature of the water leaving the condenser which acts on a bellows filled with a volatile liquid or on the principle of a spring loaded diaphragm subjected to the condenser pressure. Finally the excess pressure shut off is another loaded diaphragm so connected as to break the electric circuit should the pressure become greater than the safety limit.

Household Refrigerating Machine.—The household refrigerating machine is simply an adaptation of the automatic principles just enumerated. The refrigerating machine is very nearly always a reciprocating compressor with either one or two cylinders. The use of the absorption machine with either electric or gas heat has been advocated but has not been adopted by the public to any extent. When the latter is used it is intermittent in action except in the case of the machine using an inert gas in the evaporator side in order to overcome the necessity of the use of an expansion valve.

The household machine uses sulphur dioxide nearly always as the refrigerant. [See REFRIGERATORS (HOUSEHOLD).]

Heat Transfer.—The subject of heat transfer is of the great-

est importance in refrigerating industries. In cold storage plants it is necessary at times to install a thickness of 8 in. or more of corkboard on the walls, ceilings and floors. The best insulation for cold temperatures is one that is water-proof, that has a low value for the coefficient of heat transmission and is easily erected in place. The low value for the heat transmission is obtained by means of small air cells in the structure as is found in cork, wood and vegetable products, mineral wool and hair felt. The insulating property of the material is obtained from the effect of the air cells which are so small as to prevent convection currents, and so the statement is frequently made that the material which has the greatest number of air cells has the greatest value as an insulator. However, in refrigeration, the tendency is to absorb moisture from the air and to have it collect on the coldest surface. Therefore the material must be made waterproof if it is not so naturally. Saw-dust, shavings and materials of a compressed vegetable nature like corn stalks, sugar cane stalks, straw, etc., are suitable as heat insulators providing they are water-proofed. As this is not practical in a number of cases except by the use of waterproof paper such construction is not used in the best installations.

Formula for Heat Transfer.—If the value k of the coefficient of heat transfer is known in B.T.U. per square foot per one degree difference of temperature per hour then the total heat transfer per hour is found by $Q = A k t_m$ where Q is the total heat transfer in B.T.U. per hour, A is the area of the surface in square feet and t_m is the temperature difference on the two sides of the surface. The coefficient of heat transfer (k) must be found by experiment and certain of these are given in Table III. If a built up structure is used, composed of several thicknesses of material then the formula usually employed is:

$$k = \frac{1}{\frac{1}{F_1} + \frac{1}{F_2} + \frac{T_1}{C_1} + \frac{T_2}{C_2}} \quad \text{where } T \text{ is the thickness of each material in inches and } C \text{ is the coefficient of conductivity in B.T.U. per 1 inch thick.}$$

TABLE III.—Coefficients Based on Heat Transmission Tests (B.T.U. per Hour)
(From Bulletin 100, Eng. Experiment Station, University of Illinois, by Willard and Lichty)

Material	C per 1 in. thickness per square foot per 1° F	F Still air per 1° F
Brick wall (mortar bond and dry conditions)	4.00 (5.00)	1.40
Concrete, 7-2-4 mixture	8.30	1.30
Wood (fir, one surface finished)	1.00	1.40
Corkboard	0.33	1.25
Magnesia board	0.50	1.45
Glass (actual glass 91.4% of total area)	2.06	1.5 to 2.00
2 in. tile, $\frac{1}{2}$ in. plaster on both surfaces	1.00	1.10
4 in. tile, $\frac{1}{2}$ in. plaster on both surfaces	0.60	1.10
6 in. tile, $\frac{1}{2}$ in. plaster on both surfaces	0.47	1.10
2 in. tile, plastered as above and roofing covered	0.84	1.25
Asbestos board	0.30	1.60
Sheet asbestos	0.30	1.40
Double glass, $\frac{1}{2}$ in. air space (glass 60-3%) of total area	1.50**†	2.00
Roofing*	5.30†	1.25
Air space†	1.00-1.70‡	
Mortar	8.0	0.93
Shavings	0.42	

*Calculated from values of C for 2 in. tile with and without roofing.

† $\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2}$

‡See "Air Spaces."

**Per square foot of actual glass set in wood frame but based on total heat transmitted.

‡For thickness and construction stated, not per 1 in. of thickness.

It has been found that the surface film offers a high resistance to the transmission of heat and in the formula the values F_1 and F_2 refer to this surface resistance. For outside weather conditions it is usual to consider the value of F_2 as equal to $3F_1$.

The coefficient of heat transfer (k) for refrigeration piping is

Material	Conductivity, B.T.U. per square foot per degree difference of temperature per hour	Density	Nature of material
Air	0.167		Horizontal layer heated from above
Colorax	0.221	0.064	Fluffy, finely-divided mineral material
Hair felt	0.246	0.27	Hair felt between layers building paper
Keystone hair	0.271	0.30	
Pure wool	0.242	0.107	Firmly packed
Pure wool	0.242	0.103	Firmly packed
Pure wool	0.262	0.061	Loosely packed
Pure wool	0.292	0.039	Very loosely packed
Cotton wool	0.292	0.100	Firmly packed
Insulite	0.296	0.19	Pressed wood pulp
Corkboard (pure)	0.317	0.18	
Granulated cork	0.34	0.160	
Edgrass	0.321	0.15	Inclosed in burlap
Flaximum	0.339	0.18	Vegetable fibres, firm and flexible
Fibrolite	0.329	0.18	Vegetable fibres
Balsa wood	0.346	0.12	Very light and soft
Rock cork	0.346	0.33	Pressed rock wool with binder, rigid
Waterproof lith	0.409	0.27	Rock wool, vegetable binder, not flexed
Pulp board	0.433		Stiff pasteboard
Air cell, 1 in.	0.446	0.14	Corrugated asbestos
Air cell, 1 in.	0.479	0.14	paper enclosing air spaces
Asbestos paper	0.491	0.50	Firm but easily broken (Block)
Insularious earth	0.579	0.69	
Fire felt (sheets)	0.596	0.42	Asbestos sheets coated with cement, rigid
Fire felt, roll	0.637	0.68	Soft, flexible asbestos
3 ply Regal roof- ing	0.696	0.88	Flexible tar roofing
Asbestos mill board	0.847	0.97	Pressed asbestos, fairly firm, easily broken
Cypress	0.657	0.46	
White pine	0.792	0.50	
Virginia pine	0.957	0.55	
Oak	1.000	0.61	
Hard maple	1.125	0.71	
Asbestos wood	2.710	1.97	Asbestos and cement

TABLE IV.—Values for the Coefficient of Heat Transfer for Piping
(B.T.U. per sq. ft. per degree difference of temperature per hour)

	B.T.U.
Can ice making piping	
Old style feed, non-flooded	12 to 15
Flooded	20 to 40
Ammonia condensers	
Submerged	30 to 40
Atmospheric, gas entering at the top	60 to 65
Atmospheric, drip or bleeder	125 to 200
Flooded	125 to 150
Shell and tube	150 to 300
Double pipe	150 to 250
Baudolot coolers, counter-flow, atmospheric type	
Milk coolers	75
Cream coolers	60
Oil coolers	10
Water coolers (for direct expansion)	60
Water coolers (for flooded)	80
Brine coolers	
Shell and tube	90 to 200
Double pipe	150 to 300
Cooling coils	
Brine to unagitated air	2 to 2½
Direct expansion	1½ to 2
Water cooler, shell and coil	15 to 25
Liquid ammonia cooler, shell and coil accumulator	45
Air dehydrator	
Shell and coil (brine in coil)	5.0
and coil	3.0
Double pipe	6 to 7
Superheat remover, shell and tube	15 to 25

extremely important, but is known to a slight degree only. The reason for this is that a large number of values are obtainable unless exactly the same conditions exist in each case. The value of k is influenced to a very large degree by the effect of stagnant films of fluids adjacent to both surfaces, to the kind of material, the kind of fluid on either side of the metal, the amount of scale or dirt on the surfaces and particularly on the velocity of flow of the fluids receiving or giving up heat to the metal. In calculating piping the best that can be done, then, is to give average values for k or a range of values which can be obtained by altering the conditions either by the velocity of the water, brine or other fluid past the heat transfer surface, the mean temperature difference on the two sides of the surface or by cleaning the surface. Table IV. gives values usually accepted in good practice. The surface of the piping is usually taken as the outside surface, except for ammonia condensers where the surface is taken as that adjacent to the refrigerant.

Methods of Cooling.—Mechanical refrigeration as understood at the present time means the absorption of heat by a volatile liquid in consequence of which the liquid boils. The usual method of procedure is to use direct expansion piping whereby the liquid boils in the pipes situated in the rooms to be cooled, or by first cooling brine and then by circulating the brine through the piping. The arrangement of the piping may be along the walls or under the ceiling one example of which is shown in fig. 2. In cold storage refrigeration natural air circulation is resorted to almost entirely, in which case the velocity of the air in contact with the pipes is very low thereby resulting in a low value of the coefficient of heat transfer.

In some exceptional cases a bunker room is installed. Such an arrangement of piping, which may be in an ante-room, a corridor or in a separate room, is the suitable nesting of the piping in an enclosure whereby the air may be forced past the piping and into the room. The bunker system requires, then, a forced circulation of the air. The advantages are in being able to use less pipe and in being able to keep the refrigerant out of the room if such a matter is an asset. The disadvantages are in having to provide power for circulation and in the difficulty in cleaning the piping should frostation accumulate.

At times there is an advantage in having a hold-over arrangement of tanks, as shown in the figure as 8 in. tubes. By this

Fig. 2

scheme the brine in the tubes is cooled during the day time operation of the refrigerating machine and this cold brine will assist in holding the temperature by absorbing the heat generated by the effect of heat leakage, chemical action of the various commodities, etc.

When brine is used the method of cooling is by the use of the multi-pass shell and tube brine cooler. Such an apparatus has the brine inside the tubes, which are usually 2 in. in diameter and it is designed for 2, 4, 6 or 8 passes of the brine. The ammonia is inside the shell and its boiling action is similar to that of the

REFRIGERATION EQUIPMENT AND MACHINERY FOR MAKING ICE

1. Refrigerating equipment for air conditioning the Capitol, Washington, D.C.
2. Refrigerant compressor (foreground) installed in building for air conditioning. In the background is an evaporative cooler for the hot refrigerant gases.
3. Ammonia compressor for ice making. Two compressors are coupled to a single synchronous motor.
4. Freezing tank filled with brine for making ice. Ammonia pipes absorb heat from the brine. A group of cans filled with water is placed in the tank and their contents are frozen to a solid.
5. Can-filling apparatus. The cans are conveyed by the crane to the freezing tank.
6. Cans are emptied, and the blocks of ice are transferred on a conveyor to storage.

horizontal return tubular boiler in the generation of steam. The gas-releasing surface and the gas volume are sufficient to prevent the liquid returning through the suction pipe line to the compressor. Besides the shell and tube brine cooler the shell and coil and the double pipe designs are used for carbon dioxide installations and the double pipe for ammonia. In the case of carbon dioxide the unit pressure is so great that the refrigerant is kept inside the pipes.

APPLICATIONS OF REFRIGERATION

Refrigeration developed from its application in the brewery industry and more or less academic uses in other directions to a very important economic position. Some details of a few of these applications are described below.

Cold Storage.—Cold storage is one of the essential uses of mechanical refrigeration. By its means the season for fruits and vegetables is increased from a few weeks to from four to six months. Eggs may be kept from the period of great plenty in the early spring until fall if necessary, whereas the modern meat packer could not exist without refrigeration. In the latter case the animals are slaughtered under hygienic conditions and the meat is promptly chilled or frozen. Conditions of handling and holding the carcasses are as ideal as possible and shipment may be made in refrigerator cars to the retail trade.

TABLE VI.—Approximate Cold Storage Temperatures

Article	Temperature, degrees F.	Article	Temperature, degrees F.
Apples	30	Huckleberries, frozen	20
Asparagus	35	Ice cream, short carry	15
Bananas	55	Lemons, short carry	50
Beans, fresh	32	Lemons, long carry	35
Beef, dried	35	Lamb	40
Beef, fresh, short carry	45	Lard	40
Beef, fresh, long carry	30	Lavender	45
Beef, dried	35	Maple syrup and sugar	40
Beer, in barrels	32	Mints canned	45
Beer in bottles	45	Meats, salt, after curing	35
Berries, fresh, short carry	40	Milk, short carry	45
Buckwheat flour	40	Nutty stock	35
Butter	14	Nuts in shell	30
Butterfat	30	Onions	40
Cabbage	40	Onions, short carry	35
Cantaloupes, short carry	35	Oranges, long carry	34
Cantaloupes, long carry	33	Oysters in shell	41
Carrots	33	Oysters in tubs	35
Celery	32	Peanuts	32
Cheese, long carry	35	Peaches, short carry	50
Chestnuts	32	Pears	33
Chocolate dipping room	58	Pears, dried	45
Cider	32	Plums	33
Cigars	41	Potatoes	34
Corn, dried	45	Poultry, dressed, ice	28
Cornmeal	42	Poultry, after frozen	30
Cranberries	33	Poultry to freeze	0
Cream, short carry	33	Raisins	55
Cucumbers	32	Ribs, not brined	30
Currants, short carry	32	Salt meat curing room	32
Dates	55	Sardines, canned	40
Eggs	55	Sauces	40
Figs	55	Shrimp	30
Fish, not frozen, short carry	18	Shoulders, not brined	30
Fish, fresh water, frozen	15	Sugar	45
Fish, salt water, not frozen	15	Syrup	45
Fish, to freeze	5	Tenderloins	35
Fish, dried	5	Tobacco	42
Flowers, cut	30	Tomatoes, ripe	42
Fruits, canned	40	Watermelons, short carry	40
Fruits, dried	40	Wheat flour	42
Furs	25	Wines	40
Gams, short carry	35	Woolens	35
Gams, after frozen	10		
Ginseng	30		
Ginger ale	30		
Grapes	30		
Hams, not brined	30		
Hops	45		
Honey	32		
Hops	32		

The Packing Plant.—The method of chilling meats just received from the killing floor is not standard. As a rule the loft system is used, this upper portion being separated from the storage room below by means of a false ceiling. When brine is used it may be passed through pipe coils, or it may be made to come into actual contact with the air in the form of a finely divided spray, using a nozzle similar to that used in the washing and conditioning of air. By this means an intimate mixture of air and brine is obtained inasmuch as the air has to pass through a curtain of finely divided brine. The air in the room is kept in constant circulation by the flow of the brine, and the temperatures of the air in the different parts of the room are almost uniform. Where hand room does not permit the use of a spray loft, the brine tube or brine box system may be used to advantage. In these cases the brine spray is confined to a limited space and the air has a forced circulation on account of the action of the sprays. Storage space may be piped in the usual manner.

Marine Refrigeration.—Marine refrigeration has three kinds of refrigeration equipment: (1) Fruit carriers require forced circulation of cool air with some fresh air. (2) Frozen meats require no air circulation but do require good insulation and a storage temperature of from 12° to 15° F. (3) Chilled meats require a heavy piping ratio with the pipes located under the ceilings. The temperature of the cold storage rooms must be controlled within a small temperature variation.

Ice Making.—There have been numerous methods of manufacturing ice but the only method now installed in the United States is the "can system." In the "can system" the water to be frozen is placed in galvanized iron cans which are lowered into a brine at a temperature of from 14° to 17° F. The water in the cans may be either distilled water or drinking (so-called raw) water.

The brine in the tanks may be cooled by having direct expansion piping in the brine between the cans, or by the use of brine coolers. The old form of direct expansion piping was very inefficient because of the disregard of the principles of heat transfer. Improvements have been made of recent years by reducing the length of the coils so as to permit the gas formed by evaporation of the refrigerant to return quickly to the compressor, by the use of the flooded system whereby the coils are kept much more full of liquid refrigerant, and by the use of an accumulator or other device to prevent the liquid from the con-

Comfort Cooling.

The term "relative humidity" is understood to be the ratio of the weight of water vapour in pounds actually present in one pound of dry air to the weight of water vapour that could be present if the air was saturated. In comfort cooling, the air, cooled to the required water vapour content (absolute humidity) must be mixed with air not cooled, or it must be heated to the required temperature before admission to the space to be conditioned. The entrance temperature of the conditioned air should never be more than 8° to 12° F. below the required room temperature. In some applications of air conditioning requiring refrigeration, and particularly in industrial cases, it is possible to deliver the cooled air at relatively high velocities, and much colder than 12° F. below the room temperature, near the ceiling where it mixes quite thoroughly with the air in the space to be conditioned before contact is made with the occupants of the room. (See also AIR CONDITIONING; FOOD PRESERVATION; HEATING AND VENTILATION; THERMODYNAMICS.)

REFRIGERATORS (HOUSEHOLD). Mechanical or automatic refrigerators may be either of the compressor or absorption type. Both have a closed system in which the refrigerant circulates. In the evaporator, the part of the system inside the refrigerator, the liquid refrigerant changes to a gas, removing heat from the food chamber in the process. In the condensing coil it is cooled by air passing over the coils and changed to a liquid again. A thermostat (g.v.) may be regulated to produce the temperature desired.

The compressor system uses a small motor, $\frac{1}{4}$ to $\frac{1}{2}$ h.p., to start the cycle of operation. It forces the gaseous refrigerant from the evaporator into the condensing coils. From the coils it passes through a valve into the evaporator. The valve may be the expansion type, through which the refrigerant is sprayed into the evaporator in such a fine stream that it is partially vaporized immediately, or a float type which allows a relatively large amount of liquid refrigerant to collect in the evaporator. The cycle then repeats itself.

The functioning of the absorption system depends upon the fact that water absorbs ammonia gas in the cold but is easily sepa-

rated from it again in the presence of heat.

Heat, usually from a gas or oil flame, is used in the generator to bring about the separation. The ammonia, free from the water, passes into the condensing coils, is liquefied and flows into the evaporator, where a medium of hydrogen reduces the pressure sufficiently to allow ready evaporation. From the evaporator the ammonia-hydrogen gas combination passes into the absorber, where a spray of water from the condenser absorbs the ammonia. The insoluble hydrogen returns to the evaporator. The ammonium hydroxide flows to the generator to start the cycle again. Heat and cold exchangers complicate the construction of the system, but increase its efficiency.

As has been noted, ammonia, because of its affinity for water, is the refrigerant used in the absorption system. Sulphur dioxide and recently dichlorodifluoromethane are most commonly used in the compression system.

Certain characteristics are desirable in a refrigerant. It should be stable under frequent change of state, noninflammable and nontoxic. It should have moderately high latent heat, a low condensing pressure and no effect on metals or lubricating oils.

None of the refrigerants used complies with all the requirements, but those mentioned have the necessary latent heat and usable operating pressure to meet the demands of construction in household-size refrigerators. Dichlorodifluoromethane is nontoxic. Ammonia and sulphur dioxide are considered nontoxic in the amounts present in five to eight cubic foot boxes, under usual home ventilating conditions. (See REFRIGERATION AND ITS APPLICATION.) (L. J. P.; X.)

REFUGEES AND THE EXCHANGE OF POPULATIONS.

TIONS. In the early history of European civilization wars and conquests were often followed or accompanied by considerable movements of population. Sometimes the two went necessarily together, because the motive for war was the desire for richer lands on which the conquerors wished to live; sometimes the movement of population resulted from the ferocity of the invaders who drove whole populations away from the countries which they had inhabited.

For a long period this feature of warfare disappeared, but with World Wars I and II it once more recurred. The events of 1914-18 caused greater movements of population from one place to another than there had been for centuries before. In some cases, it is true, these movements, though large, were only temporary. For example, although the Belgian refugees who fled from the German invaders in 1914 were very numerous, and although practically all of them remained away from their homes until the end of 1918, they did not attempt to create a new life or to establish new homes outside their native land; their migration was only temporary, like that of the refugees who fled from the invaded provinces of France, Italy and Rumania, and to a smaller extent from all the territories occupied by enemy troops during World War I.

But in other cases, great masses of refugees who left their homes when the tide of war swept over them had little prospect of ever returning or of recreating their previous life there. This was the situation, for example, of a considerable proportion of the inhabitants of the Balkan peninsula.

MOVEMENTS IN VARIOUS COUNTRIES, WORLD WAR I

Excluding such temporary movements as those of the Belgians, the emigrations of war refugees of different nationalities were roughly as follows:

Russians.—Between 1917 and 1920 nearly 1,500,000 political refugees from Russia were thrown upon the charity of Europe. Some of these refugees were prisoners taken by the Germans and Austrians during the war, who refused to return to Russia. A great number were members of the defeated armies of Koltchak, Wrangel, Denikin and others. Many of the refugees were women and children who fled from the bolshevist revolution. In the earlier days of their exile they were dispersed as follows: Germany 300,000, Poland 400,000, France 400,000, Constantinople 100,000, Yugoslavia 50,000, Bulgaria 30,000, Czechoslovakia 26,000, Rumania and Greece 50,000, Baltic states 100,000. In addition a large number, at least 100,000, fled eastward into China.

Greeks.—As the result of warlike operations there fled into Greece between 1915 and 1922 1,250,000 Greek refugees from

Asia Minor and eastern Thrace and 50,000 from Bulgaria. In addition there came under treaties for the exchange of population from Bulgaria a further 50,000; from Asia Minor approximately 100,000.

Armenians.—From the year 1915 onward there were expelled from their dwellings in Asia Minor some hundreds of thousands of Armenians. Great numbers of them perished in their wanderings in the mountains; some thousands succeeded in making journeys on foot as far as Mesopotamia; others sought protection in the Russian empire. In 1921 the independent Armenian republic of Erivan, with an Armenian population of 800,000, adopted the soviet régime and became part of the Union of Soviet Socialist Republics. To its original population, 300,000 to 400,000 additional refugees from Turkish Armenia were shortly added, and in spite of their great suffering, they were absorbed with remarkable rapidity into the economic system of the country. It was further estimated that more than 300,000 other Armenians were scattered more or less in destitution over Russia and the near east, particularly Bulgaria and Greece. In 1921 100,000 fled to Syria, many of whom became Syrian subjects in the territory then under French mandate; more than 60,000 fled in the following year to Greece, 35,000 to Bulgaria and 20,000 to 30,000 more fled to the republic of Erivan.

Bulgars.—From 1918 onward a large number of minorities of Bulgarian or quasi-Bulgarian race and language fled from their homes in the Dobruja, in Macedonia and in eastern and western Thrace. It was calculated by the Bulgarian government that their total number amounted to almost 500,000. In addition, about 75,000 Bulgars voluntarily emigrated to Bulgaria from Greece under the terms of the Greco-Bulgarian Exchange of Populations treaty.

Turks.—Approximately 50,000 Turks fled from eastern Thrace and Smyrna when these territories were occupied by Greek forces in 1919, but returned to their homes in 1921. In addition approximately 350,000 to 400,000 Turks were moved from Greece (most of them from Macedonia, Crete and western Thrace) to Asia Minor under the terms of the Exchange of Populations treaty made at Lausanne in 1923.

Effects.—Broadly speaking, the general features of these movements of population during and following World War I may be summarized as follows:

The great emigration of Russian political refugees was, in the first instance, regarded as an almost unmixed evil both for Europe and for the refugees themselves. Their great suffering was not, in the early stages, compensated by any considerable political or economic gain. This is not equally true, however, of the movement of population in the Balkans and in the near east. These movements at least accomplished a great deal toward effective unmixing of the populations in these areas. The mixture of populations had led to so much political trouble in modern times that this unmixing process must be regarded as a very considerable advantage.

Further, in certain countries the influx of refugees, while at first it appeared to be a disaster, in the long run proved to be a source of strength. This was particularly true of Greece, where, thanks to arrangements which will be mentioned shortly, the refugees were absorbed very quickly into the economic system of the country, where they immensely increased the agricultural production and imported industries formerly unknown. There is no doubt that they thus improved the political position of Greece by giving it a homogeneous and vigorous new population and by increasing the economic wealth of the nation as a whole.

In Bulgaria, however, the process was much slower, as the refugees showed less inclination to accept their exile as definitive and to settle down in new homes, than did those who went from Asia Minor to Greece.

Another result of general importance which followed the movement of population caused by World War I was that Asia Minor was left almost exclusively to the Turks. Hitherto inhabited by a very mixed population, including elements which continued the traditions of the ancient civilization of Byzantium, there were now few of these elements left. Furthermore it should be noted

that the Russian emigration, which, as already stated, was regarded as an unmixed evil for the refugees and for the countries offering them hospitality began under the guidance of the League of Nations and the International Labour office, in certain countries, especially France, to constitute an important reconstructive economic factor.

Treaties of Exchange.—Under these treaties, the most important of which were the Greco-Turkish and the Greco-Bulgarian, impartial committees consisting of one representative from each government and two or three impartial experts appointed by the League of Nations supervised or actually carried out the transportation of the persons moved from one country to the other, valued their property, kept an exact record of it and established their claim for this value against the government of the country to which they went. These treaties of exchange worked with varying success.

So far as the Greco-Turkish treaty was concerned, its principal and most necessary effect was to make room in Greece, by the removal of 350,000 Turks, for a great part of the incoming flood of refugees, who found in the evacuated Turkish properties fields and houses ready for their use. Without this treaty of exchange, and without a refugee settlement loan floated under the auspices of the League, the absorption of the Greek refugees into productive employment in their motherland could never have been done.

On the other hand, the fate of the Turks transported under the treaty from Greece into Turkey and in the absence of such a loan, appears to have been less happy. Official information was not disclosed, but it is obvious that the arrival of 350,000 refugees in a country whose total population did not exceed 5,000,000, necessarily imposed a heavy burden on its resources already straitened by many years of war.

Of the Greco-Bulgarian treaty of exchange, it is enough to say that while the working of its machinery was slow, it laid the foundation for an unmixing of the population in Greek Macedonia and in parts of Bulgaria.

Work of the League of Nations.—The other personal and economic problems which were raised by the refugee movements above described were dealt with partly by individual governments and partly by the League of Nations. To take the Russians first, many governments throughout Europe accorded them particular privileges and gave them much state help, estimated at £2,000,000 per annum—in particular Yugoslavia, Czechoslovakia and Bulgaria deserve mention. The League of Nations and the International Labour office also played a considerable part through the action of the delegations established in Constantinople and in the Baltic states, Rumania, China, Bulgaria, Greece, Serbia, Germany, Poland, France and other countries, in breaking up the most disastrous congestions of refugees in places where no employment could be found, for example, in Constantinople and Greece; in placing some hundreds of thousands in employment in no fewer than 50 different countries; in securing for the refugees in many countries legal protection, freedom of movement in search of employment and a new form of so-called "League of Nations passport" which secured the recognition of over 50 governments, under which they were enabled to travel from one country to another; and even in securing for a small number who desired it, repatriation to their native land. Under the auspices and with the help of these League offices, large movements of Russian refugees were carried out to France, where some thousands were settled as tenant farmers and in industry, to the United States, to Canada, to South America and to other countries where employment could be found.

For the Greek refugees the League did still more. Through its machinery a loan of £12,000,000 for their settlement in agricultural and other employment was obtained, and under the international control of a League commission this settlement was carried out with remarkable success.

For the Armenians, who did not enjoy the protection of the government of the Turkish republic, the same passport privileges and legal protection were obtained through the machinery of the League as had previously been obtained for the Russians.

(F. N. M.; X.)

CONDITIONS BETWEEN WARS

The death of Fridtjof Nansen in May 1930 was a distinct loss to the refugees whose problems had absorbed his attention during the last ten years of his life. After a year of study and uncertainty the League of Nations established in 1931 the Nansen International Office for Refugees to carry on the work which Dr. Nansen had initiated.

The League, while accepting responsibility for the legal protection of refugees, had always considered its interest in refugee problems to be of a temporary nature. Consequently the new Nansen office was established as an autonomous body under the authority of the League of Nations with mandates to conclude its affairs by 1938 and to restrict its humanitarian activities to the co-ordination of the efforts of private organizations engaged in administering relief to refugees.

In order that the legal protection of refugees might be assured after the closing of the Nansen office, the League of Nations provided, through the medium of the convention of Oct. 28, 1933, for the issuance of Nansen identity certificates by the governments signing the convention and for rights of residence and employment and other benefits for Russians, Armenians and assimilated refugees then under the protection of the Nansen office. In 1938, after the Nansen office had concluded its activities, the League constituted a new high commissioner to deal with refugees hitherto coming under the Nansen office and the office of the high commissioner for refugees coming from Germany.

Saar.—After the plebiscite in the Saar in 1935 approximately 7,000 former residents of the Saar left that territory, most of them to settle in France. This new group of refugees was added by League action to those already under the protection of the Nansen office and a recommendation was made to the governments that Nansen identity certificates be issued to them.

China.—The war in China beginning in 1937 precipitated one of the largest internal migrations in modern history. It was estimated that approximately 30,000,000 Chinese fled before the Japanese armies in two substantial movements from the coast areas to the agricultural hinterland—one from central China and the southeast to the southwest and the other from the northeast to the northwest. Apart from the problem of internal displacement in China the Chinese government was later concerned, at the end of the war, with accomplishing the return of 135,000 overseas Chinese driven back to China by the war to their former homes in countries of southeast Asia. These overseas Chinese had played an important role in the economy of China and the resumption of their trading activities was a matter of importance to China's economic recovery.

Germany.—When the Nazi party assumed control of the German government in 1933, thousands of new refugees were dispersed over central and western Europe in the beginning of a movement which later gained momentum during World War II. Those in Germany who opposed the Nazi political philosophy—non-Aryans according to the Nuremberg laws, scientists, intellectuals, authors, artists, the members of other liberal professions and labour leaders—were first removed from government posts and later from private positions in the universities, publishing houses and business, were arrested and confined in concentration camps, deprived of their property and citizenship and finally driven from Germany, to find new places of livelihood as best they could in other countries.

Neighbouring countries—Austria, Hungary, Poland, Czechoslovakia, Switzerland, Belgium, the Netherlands and France—accepted the refugees, often in flight over their borders at night, in the expectation of extending hospitality to them for a temporary period until they could emigrate to places of permanent residence overseas. Approximately half of the Jewish refugees who left Germany in the early days of the persecution migrated to Palestine.

The German *Anschluss* with Austria in March 1938 added new thousands to the stream of central European refugees, who were already taxing the capacities of the countries of temporary refuge of western Europe. In an effort to substitute planned migration for the chaotic dispersion of refugees, President Franklin D.

Roosevelt summoned 32 governments to the Evian conference of July 1938.

Offers to receive refugees for permanent settlement were not forthcoming at Evian, however, with the exception of the Dominican Republic, which offered to accept 100,000 for settlement in agriculture.

The Intergovernmental Committee on Refugees, composed of the governments which had met at Evian in July was organized in London in Aug. 1938. It was believed at that time that the committee, lacking refugee-producing countries in its membership and free, in comparison with the high commissioners of the League of Nations, to negotiate on behalf of refugees who had not yet left their countries of origin but were under pressure to do so, would soon be able to resettle the refugees from Germany and Austria and an additional 185,000 from Czechoslovakia on a pro rata basis in receiving countries. This expectation was not realized.

Spain.—On the collapse of the loyalist army in Spain in Feb. 1939 some 340,000 refugees burst over the border into France. While at first there was indecision in France with respect to admitting the refugees, the final decision was to intern them in refugee camps at Argelès-sur-Mer and Cyprien. Since many of the refugees were fleeing primarily from military action, repatriation to Spain started immediately after the end of the war. However, some 40,000 were political refugees who could not return to Spain with safety and they eventually were placed in labour camps and absorbed in French industry. Others migrated to North Africa, Mexico, the Dominican Republic and Latin and South American countries. (J. G. McD.; X.)

REFUGEES IN WORLD WAR II

Poland.—The German invasion of Poland in Sept. 1939 precipitated an eastward movement of refugees far larger in volume and more rapid and violent in action than the westward movement which had been in process since 1933. Poland's population of 3,000,000 Jews constituted the majority of those affected by the advance of the German armies eastward, but as the war was fought more bitterly, distinctions between the treatment of Jews and Poles at the hands of the Germans became less marked. Fewer than 200,000 refugees from Poland escaped into the Baltic countries and southward into Rumania, Hungary and Bulgaria. More than 1,175,000 Jews became subject to German control in the area of former Poland that was incorporated into the German reich and in Government-General Poland.

Unknown numbers of Polish and Jewish refugees who resided in or fled into the area of former Poland which was occupied by the forces of soviet Russia were moved eastward to Siberia and southeastern Asiatic Russia.

The conquest of Poland also created numerous cross currents of population movements. The policy of the German reich was to repatriate German minorities in eastern and southwestern Europe to the *Altreich*. A treaty concluded with Italy in the fall of 1939 providing for the return of some 270,000 Germans from the south Tirol was the first effort to implement this policy. Later similar treaties were signed with Latvia and Estonia for the return of approximately 75,000 Baltic Germans.

Some 300,000 Germans were also repatriated from Bukovina, Bessarabia and Rumania.

As the members of these German minorities in other countries returned to Germany they crossed the paths of the 300,000 to 400,000 Jewish refugees from Germany, Austria and Czechoslovakia who were constantly being deported eastward to the ghettos established in Warsaw, Lublin and Lwów. These constituted the remainder of the refugees who had been unable to escape from central Europe before the outbreak of the war. The last to escape had gone by boat to Shanghai or through Poland and across Siberia to Harbin and Vladivostok and thence on to the Philippines or to the western hemisphere through Kobe and Yokohama.

As western Poland was incorporated into the reich both Poles and Jews were driven eastward into Government-General Poland. It was estimated by Polish sources that more than 1,200,000 Poles had been moved into Government-General Poland by Germany

by the end of 1939. Germans in Government-General Poland were returned to Germany. Germans were also moved from southern and eastern Poland occupied by soviet Russia to Germany.

From this area Poles and Jews were evacuated far eastward into Russia to be replaced by a Russian infiltration westward.

Finland.—Finns from the Karelian isthmus, ceded to Russia by the peace treaty between Russia and Finland after the winter war of 1939-40, were resettled in the diminished area of that hard-pressed country. More than 400,000 people had to be placed on the land or in industry at a time when the resources of the Finnish government were exhausted by the war.

Some assistance was provided by private funds raised in the United States.

Norway.—Norway faced a similar problem of internal resettlement after the German invasion. Approximately 400,000 people were moved from the coast defense areas into the interior of the country, including many who had resisted the invasion in the short-lived defense of their country.

Low Countries and France.—The advance of the German armies into the Low Countries of western Europe in the spring of 1940 uprooted civilian populations on a scale comparable to that precipitated but a few months earlier by the invasion of Poland. This movement of about 3,000,000 Dutch, Belgian and French people in flight to southern France in advance of the German armies was joined by some 140,000 refugees from central Europe who had found temporary respite in the Netherlands, Belgium and France.

The great majority who had fled to safety from military actions returned to their homes after the signing of the armistice between France and Germany, which illustrated the generally temporary character of such war refugee movements.

England after the flight of its defeated army from Dunkerque found itself harbouring some 70,000 central European refugees in addition to the members of the military forces of its allies who had escaped with its own forces. The threat of an impending German invasion from the continent and the fear of "fifth columnists" among the refugees, understandably resulted in the internment of all. Later, when the defenses against invasion were strengthened, the great majority of the refugees were released.

Balkans.—In the late summer and fall of 1940, Germany in its efforts to bind allies in the Balkan countries more closely to the axis cause did not hesitate to utilize minority groups as pawns in its strategy. In Vienna in Aug. 1940, Hungary was awarded part of the coveted area of Transylvania and approximately 2,500,000 people. The fact that many Rumanians were included in the transfer demonstrated again the difficulties involved in legislating boundaries in order to achieve racial homogeneity in the confused pattern of racial strains in southeastern Europe.

South Dobruja was allotted to Bulgaria, which agreed to repatriate 65,000 Bulgarians from north Dobruja. The transfer to Rumania of Rumanians in south Dobruja was also planned. Slovakia undertook to repatriate Slovaks from the protectorate of Bohemia and Moravia.

Luxembourg and Lorraine.—In the west, Luxembourg and Lorraine were incorporated as provinces into the German reich. Again non-Aryan refugees, members of the government of Luxembourg and political refugees were forced to flee. Some 20,000 of the French population of Lorraine were expelled without warning into France and only vigorous protest by the Vichy government prevented the expulsion of larger numbers from their homes. In Nov. 1940, 10,000 Jewish refugees were driven from Baden and the Palatinate into southern France.

U.S.S.R.—The advance of the German armies into soviet Russia in the summer and fall of 1941 drove before it the greatest migration of a decade in which the history of uprooted populations had exceeded in stark tragedy all previous records of modern history. No authentic figures were available, but conservative estimates placed the numbers driven eastward as between 10,000,000 and 20,000,000. More than 2,000,000 inhabitants of the invaded soviet areas survived the hardships and cruelties of the labour

camps in which they were confined during the war in eastern Europe. Similar numbers were estimated to have succumbed under the conditions of work which could only result in exhaustion and death.

German Forced Labour.—Apart from the dispersal and flight of political refugees, the transfers of German minorities in pursuit of concepts of racial purism, the transfer of minority groups as political pawns and the flight of masses of civilians from military action, the most outstanding movement of people during World War II was the draft into Germany of more than 8,500,000 workers from countries occupied by the German armies. One-fifth of these slave labourers were women. In addition, 4,000,000 workers were employed away from their homes and often outside their own countries in industrial or military labour in the occupied countries of Europe. Included in this group were many former Polish and French prisoners of war whose status under the Geneva prisoner of war convention was violated by one device or another.

After the occupation of western Europe efforts were made to enlist such labour voluntarily by inducements of high wages and promises of food rations. French prisoners of war were in the first instance returned from Germany to France and released from custody only to be confronted by various pressures to return to Germany immediately as labourers. As the demands of the German war machine increased, legal and proper methods of recruiting were abandoned for more forceful methods.

The conditions of work of the labourers from the east, chiefly Russians and Poles, were deplorable in the early years of the war. On the other hand, efforts were made by the Germans to provide better conditions of work and wages for workers from the western European countries. Finally as the sources of forced labour were exhausted, food, wages and working conditions were equalized for all in desperate efforts to secure maximum production. This policy continued until toward the end of World War II, when deterioration in German organization and control became evident and conditions in the labour camps degenerated to those prevailing in the concentration camps, where the policy appeared to be to drive the inmates to exhaustion by long hours of heavy work with inadequate provisions for food and shelter.

Included among the 8,500,000 workers drawn into Germany were approximately 2,000,000 Russians, 2,000,000 French, 1,500,000 Poles, 500,000 Belgians, 500,000 Dutch, 600,000 Italians and smaller numbers of Czechs, Balts, Hungarians, Rumanians, Danes and Norwegians.

As the German armies disintegrated in the spring and early summer of 1945 these millions of slave labourers were released by the Allied armies as were also the inmates of the concentration camps. In the early days of liberation they provided a problem for the Allied armies intent upon the final destruction of all German resistance. Food and means of care and transport were lacking. The liberated workers trekked homeward as best they could, living on the land; many were in such advanced stages of malnutrition that even hospital care which was soon organized could not save their lives.

POSTWAR PROBLEMS OF DISPLACED PERSONS

Gradually as the occupying armies stabilized conditions within Germany and Austria, orderly means of repatriation were developed. The displaced persons were removed to their home countries by train, truck and air.

Their eagerness to reach home was matched by the necessity of the Allied armies to repatriate them or to organize supply lines to feed them where they were. It proved more practical to repatriate them quickly than to move food and clothing to them in central Europe. Within six months after the cessation of hostilities in the summer of 1945 between 6,500,000 and 7,000,000 United Nations nationals had been returned to their home countries in Europe.

Repatriation slowed down substantially in the winter months of 1945 and 1946 owing to the lack of heated transportation equipment and inadequate reception facilities in the receiving countries. Efforts to re-establish the flow of repatriation in the spring and

summer months of 1946 proved unavailing. By that time it appeared that many among the former workers and concentration camp victims were unwilling to return to their countries of origin because of the political changes which had taken place in those countries during the war. More than 1,000,000 displaced persons, including approximately 600,000 Poles, 75,000 to 100,000 Yugoslavs, 250,000 former Baltic nationals and 50,000 Ukrainians, were unwilling to return. They were maintained in displaced persons assembly centres in Germany, Austria and Italy provided by the occupying military authorities and administered by the personnel of the United Nations Relief and Rehabilitation Administration which in 1946 undertook the responsibility for further repatriations.

The Jewish refugees included among the foregoing total constituted a special group. They had suffered particularly at the hands of the nazis and were reluctant to return to home areas where so many of their relatives and coreligionists had perished during the war. At the end of the war it was estimated that no more than 1,250,000 Jews remained out of a prewar population of approximately 5,500,000 in Europe excluding soviet Russia.

The numbers of Jewish refugees in central Europe were slightly under 100,000 at the end of hostilities in 1945. However, these numbers were swollen by postwar infiltrations from Poland, Hungary and Rumania to 200,000 by the end of 1946. More than 90% expressed the desire for emigration to Palestine.

The displacements of German and Austrian nationals in Germany and Austria at the end of the war were substantial. These had resulted from the dispersion of industry during the war, evacuations from bombed areas and the flights of civilians from final military action. One of these general movements was westward from the Baltic countries, Poland and East Prussia to Denmark and southwestward toward Austria and Switzerland. Some 200,000 Germans in this movement remained interned in Denmark because of the overcrowding and lack of housing facilities in Germany until late 1948.

Following the cessation of hostilities, political pressures and hatreds aroused by the war resulted in the expulsion from Poland, Czechoslovakia and Hungary under the Potsdam agreement (1945) of more than 6,000,000 members of the German prewar minorities in those countries. This substantial movement severely strained the limited housing facilities in Germany resulting from the destruction in the final stages of the war. There were similar expulsions of German minorities totalling 250,000 persons into Austria from Yugoslavia and Rumania which were not covered by the Potsdam agreement.

The presence in Germany, Austria and Italy of more than 1,000,000 United Nations refugees and displaced persons who were unwilling to accept repatriation to their home countries was disturbing to the peace and order of central Europe and a cause of political friction between friendly allied governments. The eastern European governments took the position that their nationals should return to their countries.

The position of the western democracies was that the individual should have complete freedom of choice with respect to repatriation. This principle was formally adopted by the general assembly of the United Nations in its resolution of Feb. 12, 1946 on the subject.

International Refugee Organization.—In Dec. 1946 the general assembly of the United Nations adopted the constitution of the International Refugee organization (I.R.O.) which was to take over from U.N.R.R.A., the Intergovernmental Committee on Refugees and the military authorities of the occupying powers in Germany and Austria the task of providing care and maintenance for United Nations refugees and displaced persons and of accomplishing their repatriation or resettlement. The I.R.O. came into formal existence on Aug. 20, 1948. Its constitution made no provision for the disposition of the displaced German minorities in Germany and Austria.

The preparatory commission for I.R.O. assumed the responsibility for the disposition of over 1,000,000 displaced persons in central Europe on July 1, 1947. In the first three years of operation of the preparatory commission and I.R.O. from July 1, 1947,

to June 30, 1950, these governments contributed a total of approximately \$360,000,000 for the operations of I.R.O. From July 1, 1947, to Jan. 1, 1950, the combined efforts of governments, voluntary organizations and the I.R.O. resulted in the resettlement of 760,000 United Nations refugees from central Europe. The United States accepted approximately 160,000; Israel, 131,000; the United Kingdom, 100,000; Australia, 103,000; Canada, 78,000; France, 41,000; Brazil, 27,000 and Venezuela 14,000. In the same period 68,000 had been repatriated to their countries of origin. During this two and a half year period I.R.O. had maintained more than 600,000 persons in camps for varying periods of time and provided medical care, hospitalization, vocational training, food and clothing.

In anticipation of the termination of I.R.O. services by March 31, 1951 the general assembly of the United Nations in Dec. 1949 adopted a resolution providing for the establishment of an office of high commissioner for refugees to continue the work of protection of refugees to be relinquished by the I.R.O.

Palestine.—The U.N. general assembly in 1948 was concerned with the plight of 750,000 Arab refugees resulting from the conflict in Palestine. These refugees had fled from Palestine into Lebanon, Syria, Iraq, Hashemite Jordan and Egypt and in the fall of 1948 were without means of livelihood or organized assistance.

The general assembly thereupon created the United Nations relief for Palestinian refugees and requested its government members to contribute sufficient funds for relief.

Japan.—Japanese infiltration into other countries of the far east prior to and during World War II was substantial. More than 2,000,000 Japanese were in China at the end of the war, larger numbers in Manchuria, 800,000 in Korea, 500,000 in south-east Asia and 200,000 in Australia and New Guinea. The total of displacement in Japan proper was estimated at 12,000,000 including 2,000,000 Korean labourers and their families. The repatriation of these large numbers of Japanese and Koreans began before the war was over and continued under the direction of the Allied military forces.

These infiltrations and later repatriations had their respective effects on the economies of the areas involved and left serious problems of reconstruction behind which complicated the task of post-war economic and political reorganization.

REFUSE DISPOSAL, the general term employed in the United States for the collection and disposal of the solid wastes of a community, including garbage, rubbish and ashes. (For British practice see **DESTRUCTORS**.) Garbage may be defined as the waste matter resulting from the preparation, cooking and consumption of food. Rubbish is the miscellaneous material discarded by a community as being no longer of use or value. It includes paper, rags, crockery, glassware, rubber, tin cans, wood, etc. The term ashes, as generally used, refers only to the residue resulting from the operation of heating plants in homes and small business establishments or offices. In the average city (there are wide differences in various cities) of the United States, gar-

bage comprises about 13% by weight and 18% by volume of all refuse; rubbish amounts to only 7% by weight, but to 25% by volume; ashes form approximately 80% by weight and 57% by volume of the total. Garbage weighs from 1,000 to 1,200 lb. per cubic yard, the weight varying with the season, temperature, rainfall and other factors. Of the total weight of garbage, from 60% to 65% is moisture while the combustible matter amounts to 15% or 20%. A pound of dry garbage contains about 8,500 heat units, and 40 to 60 lb. of garbage per ton can be extracted from raw garbage. Garbage attracts vermin, is unstable and decomposes quickly, producing nuisance. Rubbish breaks down more slowly and relatively without objection; it has considerable fuel value, the volatile matter ranging from 40% to 70% of the total. Ashes collected from residences and small business establishments also have some fuel value.

Quantity of Waste.—Where the collection service is good, the average daily amount of garbage collected ranges from 0.5 to 1 lb. per person. The amount of garbage appears to be increasing, and data collected from 17 cities where careful and reliable records have been kept show that in 1936 the average production was more than 274 lb. per person per year, compared to previous figures ranging from 150 to 200 lb. The daily production varies markedly with the season. In the southern states, watermelon rinds form a large part of the garbage during the late summer months. The amount of rubbish collected ranges from 50 to 175 lb. per person per year, averaging about 75 lb. The collections of rubbish remain fairly uniform throughout the year, increasing slightly during the spring and fall months. Ashes, in the northern cities, compose a large part of the refuse collected, but where climatic conditions are milder, the amount may become unimportant. Street sweepings, night soil, manure, dead animals and other wastes vary in amount according to local conditions and local regulations governing their collection. However, the collection and disposal of these wastes are not, in most cities, functions of the general refuse collection organization, but are performed by special departments. Therefore, they will not be considered here. The total amount of refuse collected per person per year ordinarily amounts to 1,200 to 2,000 lb., but because of the many factors influencing collection, the amounts reported by typical cities range from 1,000 to 2,500 lb.

Collection of Wastes.—The collection of waste is generally considered to include both the actual gathering of the garbage, rubbish and ashes, and the subsequent transportation to the points of disposal. The methods of collection vary; in *separate* collection, garbage is collected separately and apart from the other wastes which may or may not be collected together; in *mixed* collection, garbage and rubbish, or sometimes garbage, rubbish and ashes are collected at one time and from a common receptacle. A survey of 84 cities and villages showed that garbage was collected separately in 39, while in 45 it was collected with other material. The trend since 1930 has been toward mixed collection of waste. The practice of separate collection is based upon either utilization of the garbage, as in feeding to swine or reduction or on cheaper disposal of the less objectionable components of the wastes. In many cities, rubbish and ashes may be dumped or used for filling within the city limits, while garbage disposal must be accomplished at some distant point. In such cases, the saving in hauling and handling costs may be much more than the extra cost occasioned by separate collection. Where garbage is collected separately, it is the usual practice to collect it twice a week in the summer and once or twice a week in the winter; a few cities collect more frequently; many make daily collections in the business sections.

Mixed refuse, because decomposition is slower, is usually collected once or twice a week. Ashes and rubbish are generally collected weekly.

Most of the large cities and about half the smaller ones employ municipal collection, contract collection being used otherwise except in the smallest places.

Satisfactory collection and handling of refuse is impossible without proper receptacles for the storage of waste materials, and most cities have regulations covering the size, material of con-

struction and quality of garbage receptacles. They are usually required to be watertight, of impervious materials and to have a tight cover. The usual capacity is 9 to 15 gallons. Few cities require any special receptacle for rubbish or ashes, but generally provide that the former be tied in bundles, or placed in boxes or barrels; ashes should be placed in non-combustible, covered containers. Receptacles may be placed at the back door, at the alley

CHARGING FLOOR OF ONE OF NEW YORK CITY'S CENTRAL GARBAGE DUMPS, WHERE GARBAGE, MIXED WITH DRY REFUSE, IS DUMPED DIRECTLY INTO THE FURNACE

line or at the curb line. It costs more to collect from the back door, but it is the usual practice in the United States, only about 30% of the cities requiring that garbage and refuse be placed at the curb, which is aesthetically objectionable.

Collection Equipment.—Motor trucks are used almost exclusively for the collection of wastes, and the sizes of trucks used are increasing. The larger cities have found that 2 to 3-ton trucks are more advantageous and economical when equipped with 8 to 12-yard bodies. In the smaller communities, the light trucks with 3 to 6-yard water level capacity bodies predominate. Increased attention has been given to the development of tight, covered bodies; excellent larger units have been produced, but there is still a need for better equipment for use with small trucks.

Disposal.—Many methods of refuse disposal are in use in the United States, probably due to the differing conditions existing. The methods in use include dumping on land and in water, filling, ploughing under, burial, feeding to hogs, incineration, reduction, sorting and utilization. Garbage from cities is relatively rich in food values. If these values can be reclaimed, the net cost of disposal may be reduced. In addition to the food value of the garbage, the facilities for the cheap and ready disposal of rubbish and

in thin layers, and covered immediately with earth, ashes or other inorganic material. Ashes make good filling material and are used in many cities for making fills. Rubbish is frequently dumped, but because of the time required for the fill to compact, and the miscellaneous material composing rubbish, it is not as generally satisfactory. Dumps are almost certain to catch fire, resulting in objectionable fumes. To obviate this, many cities burn the combustible matter as it comes to the dump. Paper is often collected, baled and sold. Picking over the materials on the dump is quite a general custom and usually affords some slight revenue.

Sorting.—In few cities is there any organized attempt to recover materials of value in refuse, experience having shown that it is not possible to pay the cost of labour and overhead. Milwaukee has attempted salvaging, primarily to conserve dumping space which at the present rate of use will be exhausted in a few years. It has been found that ash volume can be cut in half, and that enough saleable material can be salvaged to pay much of the expense. By weight, refuse consists of 48% fine ash, 38% combustible ash, 6% tin cans and metal, 1% paper and 4% miscellaneous. Combustible ash has been used for heating city buildings.

Burial.—Few cities dispose of their garbage by burial. In case of the breakdown of other methods of disposal, burial is sometimes employed as a temporary measure. The usual practice is to place the garbage in trenches about 3 ft. deep and 3 or 4 ft. wide, the garbage being deposited in layers from 12 to 18 in. deep. Before covering, the garbage should be sprayed liberally with disinfectant

A REFUSE COLLECTION TRUCK IN SERVICE

LOADING GARBAGE WHICH CANNOT BE BURNED ON SCOWS TO BE TAKEN 20 MILES OUT IN THE OCEAN AND DUMPED

ashes and the availability of easily accessible sites for incinerators will be factors in the choice of the method to be used.

Disposal of refuse by filling in low places is common; in the larger cities and in closely built-up metropolitan areas, sites for dumps are increasingly difficult to find, requiring longer hauls, higher hauling costs and dump control costs, and increasing the cost. Garbage cannot be dumped satisfactorily, unless extreme precautions are taken, and disposal in this manner is rare, except in cases of emergency. For satisfactory disposal by dumping, garbage must be treated with a deodorant or disinfectant, spread out

or crude oil. A cover of 18 to 24 in. of earth appears to give best results. For winter disposal, the trenches must be dug before the ground freezes, and covering can be done in early spring. Sandy, well-drained soil is most suitable, and where conditions are favourable, the land can be reused in 3 to 5 years. Ploughing under of garbage is a little used method. The cover secured is very thin, and men with hoes must follow the plough.

Feeding to Swine.—This is probably the most prevalent method of garbage disposal, especially in the smaller communities. Initial costs are low and there is some return for the food value in the garbage. It is estimated that 50 lb. of garbage will produce 1 lb. of pork. Based on a live market price of six cents a pound for pork, garbage is therefore worth \$2.40 per ton, less the cost of extra haul, labour, and final disposal of the residue resulting from feeding. Recent studies by the U.S. Public Health Service have shown incidence of trichinosis in garbage-fed swine is three to five times as great as in grain-fed swine, and in view of the high human trichina infestation, the influence of public health authorities may adversely affect this method of disposal.

For utilization of the garbage by hog feeding, frequent collection is necessary. In the summer, collections should be made at least three times a week. Careful separation of the garbage is necessary, since its value as a food depends upon the care with which rubbish, glass, crockery, soap and other harmful materials are excluded. It is always difficult to find a suitable situation for a

turies the regal was a very great favourite, and although, because of the civil wars and the ravages of time, few specimens now remain, the instruments are often mentioned in old wills and inventories.

REGALIA: *see* CROWN JEWELS or REGALIA; CORONATION.

REGENCE STYLE, in architecture and the decorative arts, a name sometimes given to a style transitional between the classic grandeur of the Louis XIV work and the freely imaginative rococo of the developed Louis XV period; so-called from the fact that from 1715 to 1723 France was under the regency of Philip, duke of Orleans. (*See* LOUIS STYLES.)

REGENERATION. Terminology.—The term regeneration is usually defined as the process by which organisms replace structures or organs which have been lost by accident or mutilation. This definition is not quite adequate because its wording does not cover two phenomena which belong undoubtedly to the category of regeneration phenomena. In some invertebrates, as for instance the fresh-water polyp, *Hydra*, and the flatworm, *Planaria*, and in the starfish, a small fragment of the body can restore a complete, whole organism, rather than a structure or organ. Furthermore, many animals can restore structures which are lost in the normal course of life processes rather than by accident. The periodic moulting of feathers in birds, the shedding of fur in mammals, of the exoskeleton in arthropods or of the epidermal cornified scales in reptiles are followed by a regeneration of the discarded structures. The uppermost cornified skin layers in mammals including man are constantly worn off in small bits and replaced by active, proliferating cell layers in the deeper strata of the skin. The same holds for the continuous replacement of hair, nails and claws. The teeth are replaced only once in mammals including man, but there is a continuous succession of teeth in lower forms, such as the dogfish and shark. The antlers of deer are shed at regular intervals, and then regenerated. The periodic changes in the genital tracts of female mammals, during menstruation and oestrus should also be included here. All these instances in which replacements are part of the normal life functions are called "physiological" or "repetitive" regeneration, in distinction to "restorative" or "reparative" regeneration which follows injury. The present article deals primarily with the latter type.

There are wide differences in the regenerative capacity of different animals. The one extreme is represented by the above-mentioned invertebrates in which a part of the body can restore a whole organism. In higher organisms, as for instance, the salamanders among the vertebrates, and many crustaceans and insects, only single organs, such as limbs can regenerate, and mammals can not restore entire organs, but they can repair damage to tissues, such as bone fractures, skin and muscle injuries and peripheral nerve loss. These phenomena of tissue repair are, of course, included under the general heading, regeneration.

It has long been recognized that regeneration can be accomplished in two ways: by outgrowth of new tissue from the wound surface, or by transformation and reorganization of the remaining parts, without an outgrowth of new material. In the former case, a regeneration bud, or "blastema," is formed at the wound surface (fig. 4). It is usually cone-shaped and consists of an embryonic type of cells which gradually form the adult structures by processes of cell differentiation and growth, much in the fashion of the embryonic development. The regeneration of limbs and tails in salamanders are examples of this type of regeneration, for which the term "epimorphosis" (T. H. Morgan, 1901) has been coined. The second type of regeneration, the remodeling of old parts, has been called "morphallaxis" (Morgan, 1901). Very small fragments of a fresh-water or marine polyp, or of a planarian, undergo a change in shape instead of growing blastemas; they break down old structures, and build in their place new ones of a smaller proportion. All regeneration processes in protozoans are of this type. Occasionally, both types of regeneration take place simultaneously, and there may be no fundamental difference between them. The term "regeneration" is almost universally adopted as the all-inclusive term, with "epimorphosis" and "morphallaxis" as subheadings. C. M. Child (1941) proposes

"reconstitution" as the general term to cover all related phenomena. He uses "regeneration" in a narrow sense, synonymously with epimorphosis as reconstitution by outgrowth, and the term "reorganization" as reconstitution by internal changes.

The aim of regeneration is to maintain or restore the fitness of an organism after the loss of parts. This aim is best accomplished by a replacement of precisely those structures which were lost. However, a number of cases are known in which more than, or less than, the lost part is regenerated, and other cases in which the regenerate is structurally different from the lost part. The term "heteromorphosis" covers all types of atypical regeneration. The term "homoeosis" is used for those atypical regenerations in which the regenerate represents an organ which is different from the original. For instance, in crabs, an amputated eye stalk will, under certain conditions, be replaced by an antenna. Another type of atypical regeneration has been given special attention; namely, those instances in which the polarity of the regenerate is changed. For example, the posterior cut surface of a piece of planarian will, under certain conditions, regenerate a head instead of a tail (*see* Polarity; *Polar Heteromorphosis*). This type of polarity change is called "polar heteromorphosis."

Theoretical Considerations.—When a regeneration blastema differentiates into the head of a planarian or into the limb of a salamander, the processes which go on in the blastema are fundamentally of the same nature as the embryonic developmental processes which created these organs to begin with. Although the regeneration processes are rarely exact replicas of the corresponding developmental processes, they are alike in some fundamental aspects. Both require a building material of plastic, undifferentiated embryonic-type cells, and a set of specific organizing factors which direct and control the moulding and differentiation of such building materials. In this sense, regeneration can be defined as the revival, or reactivation, of developmental potencies in organisms which have passed the embryonic stages of development.

If one adopts this point of view, then the close affinity of regeneration processes with asexual reproduction becomes evident. In fact, in some instances it is difficult to draw the line between the two. For instance most protozoans reproduce asexually, by fission. The daughter individuals restore by regeneration those structures which they do not contain at the start of the fission. If a protozoan is cut in two by a fine instrument, the result is the same—each half regenerates the missing structures. In this instance, fission and regeneration differ primarily in the factors which set these processes in motion. Similarly, some flatworms and annelids (segmented worms) which possess high regenerative powers reproduce regularly by transverse fission or by a budding process at their posterior ends. Their regenerative potencies are, so to speak, placed in the service of reproduction. Budding is another mode of asexual reproduction particularly common among colonial forms. It is practised by coelenterates and tunicates among animals and by plants. A bud is an outgrowth on an adult organism which is an expression of the revival of growth potentialities at a localized area of the body. The parallel to regeneration is obvious. In many marine coelenterates one can readily produce a lateral regeneration bud by making a cut in the body wall (laceration). Again, the main difference between regeneration and spontaneous budding lies in the initiating stimuli.

If we consider the ability for regeneration as a residual developmental capacity which a number of organisms retain throughout adult life, we imply that regeneration is the manifestation of a universal and basic property of all organisms; namely, the capacity for growth and development. This point of view which is generally adopted did not always prevail. It was seriously contested during the second half of the 19th century. Under the impact of the theory of natural selection, another theory of regeneration was strongly advocated by August Weismann and others. This theory emphasized the usefulness and adaptive value of regeneration; it stressed the point that regeneration was apparently limited to those organs and structures which are particularly in danger of being injured or mutilated by enemy attacks. Hence it was assumed that regeneration is not part of a

basic equipment of all organisms, but is acquired secondarily as a special adaptation wherever the ability to regenerate was of crucial survival value in the struggle for existence. It was held that the all-powerful natural selection was instrumental in creating and improving the regenerative capacity. A just objection has been raised against this theory, namely, that in many instances inner organs regenerate which are not liable to injuries, as for instance, the crystalline lens of the amphibian eye, or the liver. Furthermore, we are now aware that natural selection can not create a property like regeneration, but can, at best, only improve an existing regenerative power by selecting consistently those hereditary variants which possess high regenerative capacity. For these and other reasons, Weismann's theory in its extreme form is untenable. However, its valid element, namely, the emphasis of natural selection as a mechanism for increasing pre-existing limited regenerative capacity, can be readily incorporated in the residual growth theory of regeneration.

In the following section it will be shown that, generally speaking, lower organisms have a better regenerative power than higher organisms, but that the regenerative capacity is distributed sporadically among animals and that in many instances closely related forms differ widely in their regenerative capacity. A theory of regeneration has to explain this scattered distribution of regeneration. Natural selection can not account for it, because there is apparently no close correlation between liability to injury and the regenerative power. The residual growth theory, which assumes that regeneration is a manifestation of a universal property of all organisms, has to account for the fact that this potentiality is lost in a great many forms. Two prerequisites must be fulfilled if a successful regeneration is to occur; there must be available the necessary building material in the form of embryonic-like cells, capable of growth and differentiation, and the necessary organizing factors must be present which direct the development of these cells. Regeneration may be prevented by the loss of either one or of both. The necessary building material may be lost in the normal course of development, during which embryonic cells undergo a differentiation into highly specialized tissues. This differentiation is undoubtedly irreversible in most instances, and the transformation of all cell materials into an irrevocably differentiated form is probably one reason for the lack of regeneration in highly organized animals. Some authors maintain that in some instances a differentiated tissue can dedifferentiate and rejuvenate under certain conditions, and thus become available as a source of regeneration material. Furthermore, in a number of invertebrates and lower chordates, certain embryonic cells remain in an undifferentiated embryonic condition and form a reservoir for regeneration and asexual reproduction (see below). It is obvious that regeneration is impossible in all those organisms which possess neither reserve cells nor tissues capable of dedifferentiation. The organizing or "field" factors for regeneration will be discussed below. Their loss, in the course of embryonic development, may be an alternative cause for a lack of regenerative power. Finally, an amputation stump may be potentially capable of regenerating but be prevented from doing so either by a deficiency in one of the many subsidiary agents necessary for regenerative growth, such as hormones or nerve-produced agents, or by a block from a rapidly overgrowing skin or wound scar which would prevent the outgrowth of the blastema cells. In the latter instances an appropriate treatment of the stump may call forth a regeneration where it would not occur under ordinary conditions.

DESCRIPTION

REGENERATION IN DIFFERENT ANIMAL GROUPS

The following survey is by no means complete. Only such cases were selected in which regeneration was observed in the laboratory, since the evidence from incidental findings of regeneration in animals which were caught in the field is often ambiguous and inconclusive.

Protozoa (see review by W. Balamuth, 1940).—Most Protozoa reproduce asexually by longitudinal or transverse fission, or by other modes of division. Fission requires a reorganization

and new formation of structures in the daughter individuals, and this process can be considered as a physiological regeneration. The power to rebuild structures is therefore inherent in all protozoans, and it is not surprising to find that most Protozoa can regenerate parts which were lost by accident or removed in an experiment. In all instances, the presence of nuclear material is a necessary prerequisite for successful regeneration. In ciliates which possess a macro- and a micronucleus, the former is essential; the latter is not. In forms, like *Stentor*, in which the micronucleus is represented by a beaded chain, small segments of the chain are sufficient to enable a fragment to regenerate. In *Amoeba*, which is the most primitive protozoan in that it has no highly specialized organelles, a nonnucleated fragment can grow and survive up to 30 days, but it can not divide. The most highly differentiated Protozoa, the ciliates, have been the subject of extensive studies on regeneration; *Paramecium* and *Stentor* are the favourite materials. Their regenerative power is excellent. Fragments as small as 1/64 of an individual can form a complete new organism. The new organelles are formed, either by a remodeling of the remnants of the old ones, or by breakdown of the latter and rebuilding of entirely new structures. In parasitic Protozoa the regeneration capacity seems to be poor or entirely missing.

FROM KORSCHNELT, AFTER MORGAN

Fig. 1.—REGENERATION IN THE FRESH-WATER POLYP, HYDRA. THE SHORT PIECE BETWEEN THE TWO LINES (AT LEFT) REGENERATES INTO A NEW POLYP. 1 TO 9 ARE STAGES IN THE REGENERATION PROCESS

Porifera (Sponges).—The regeneration of amputated parts in Porifera does not seem to be very extensive. However, a series of interesting experiments has revealed a remarkable capacity of the sponge cells to reorganize themselves into a whole organism, following a complete breakup of their organization. Sponges were strained through bolting-silk and thus completely dissociated. Following this treatment, small cell groups reunited into larger aggregates which reorganized themselves and formed eventually a typical sponge.

Coelenterata.—They occur in the forms of polyps and medusae (jellyfish). The well-known fresh-water form *Hydra* takes its name from the Greek mythological nine-headed monster which was believed to regenerate two heads in the place of each amputated head. The regenerative power of our native *Hydra* is at least as startling as that of its namesake. It was in this form that the Swiss naturalist Abraham Trembley made the first planned regeneration experiments (1744), which aroused a tremendous interest and were soon followed by those of R. A. F. de Réaumur, Lazaro Spallanzani and others. Small fragments of the body can regenerate a whole individual (see fig. 1). One tentacle with a small portion of the hypostome is capable of forming a new individual. The regenerative power of other hydrozooids differs in different species. *Tubularia* and other marine forms have been widely used for experiments on the physiology of regeneration (see below).

Fig. 2.—REGENERATION IN THE FLATWORM, PLANARIA. THE THREE ROWS SHOW THE REGENERATION OF THREE SHORT PIECES, a, b, c OF THE ANIMAL AT THE LEFT

considerable regenerative capacity.

Platyhelminthes (Flatworms).—This phylum includes the planarians, which have an exceedingly high regenerative capacity, and which have therefore been used more than any other form for regeneration experiments. A planarian may be cut in any direction by one or more transverse, longitudinal or oblique sec-

The regenerative capacity of the medusae (jellyfish) is much restricted. The Anthozoa (sea anemones and corals) have a

tions, and each fragment will regenerate a whole, though smaller, individual (see fig. 2). Planarians possess complex structures such as eyes, brain and pharynx. Any or all of these can be rebuilt from a fragment not containing them. It is of interest to note that of three closely related groups which are mainly distinguished by differences in the shape of the intestine (Rhabdocoela, Triclad, polyclads), only the triclad to which planarians belong have a high regenerative power, and even within this group there are great differences with respect to the ability to regenerate.

The entirely parasitic Trematoda (flukes) and Cestoda (tapeworms) have not been thoroughly investigated. They seem to lack regenerative power.

Annelida.—Regeneration in the common earthworm is well known. It can regenerate many segments at the posterior part of the body, but the regeneration of the anterior part is limited. Up to five segments can be completely restored; but, if more are removed, less than the normal number are rebuilt; no regeneration takes place if 15 or more anterior segments are amputated. Some relatives of the earthworm can do better. For instance, the fresh-water worm *Cirrodium* regenerates as many as 25 anterior segments. In another fresh-water form, *Nais*, two isolated segments can regenerate a whole worm. One of the remarkable features in these annelid regenerations is the formation of gonads in the regenerated segments, although the stumps which give rise to the regenerates may not contain a trace of gonad material. The regenerative power of the more highly specialized marine polychaetes is, in general, lower than that of the earthworm and its relatives (oligochaetes). It is very low in the Hirudinea (leeches).

Echinodermata.—The arms of Asteroidea (starfish) and Ophiuridea (brittle star) can regenerate a whole individual in some instances, even if the amputated arm contains no trace of the central disc. Occasionally, one finds on the seashore an odd-looking starfish with one or two normal-sized and several very short arms (see fig. 3). The latter are in the process of regeneration. Echinids (sea urchins) can repair damage in the skeleton and restore tube feet and spines. It is of interest to note that, according to several experimenters, the sea urchin and starfish larvae (pluteus) have little regenerative power.

FIG. 3.—REGENERATION IN THE STARFISH. ONE ARM REGENERATES A WHOLE STARFISH

tentacle at its base results in its regeneration, including the eye. However, the entire head of a snail can not be regenerated. Cephalopoda (squid, octopus and cuttlefish) can regenerate amputated arms.

Arthropoda.—The body of an arthropod has many appendages such as legs, wings, antennae, stalked eyes, mandibles and tail appendages. They are all readily exposed to accidental damage, and most of them can be regenerated when lost. This holds particularly for the best-known and most thoroughly investigated groups, the Crustacea (crayfish, crab, lobster, etc.) and the Insecta. All arthropods moult periodically, that is, they shed their chitinous exoskeleton. Its replacement may well be considered as a type of physiological regeneration. The regeneration of lost parts is, by and large, limited to those phases of their lives in which moulting occurs. For instance, insects with very few exceptions, do not moult after metamorphosis. Their regenerative power is high during larval and pupal stages but greatly reduced in the adult. The regeneration of structures like wings or legs of adult insects is either limited and incomplete or, in other

forms, entirely impossible. On the other hand crustaceans continue to moult throughout adult stages, and they are capable of regenerating organs which are as complex as are some types of legs or eyes. Some inner organs can be regenerated in insects, as, for instance, parts of the intestine and of the gonads.

Tunicata (Sea squirts, etc.).—A high regenerative power is found in the sedentary ascidians. A small part of the body can regenerate a whole individual.

Vertebrata.—In the Teleostei (bony fishes) the regenerative capacity is limited. They can regenerate the tail fins and the other paired and unpaired fins. A few other structures are known to be capable of regeneration, such as the operculum (gill cover), parts of the gills and of the lower jaw.

Amphibia.—The tailed Amphibia, or Urodela (salamanders and newts), have by far the most extensive regenerative potency of all vertebrates and have, therefore, been the favourite material for experiments on vertebrate regeneration. In particular, the limb regeneration of salamanders has been analyzed in many respects, ever since it was discovered by Spallanzani in 1763 (see below). Any part of a foot or hindlimb can be regenerated; one of the remarkable features is the precision with which the missing part is restored. If the foot is amputated (see fig. 4, level b), only this part is replaced; if the leg is removed at its base (see fig. 4, level c), it will be replaced in its entirety.

(A) FROM HANDBOOK, "MANUAL OF EXPERIMENTAL ENTOMOLOGY" (UNIVERSITY OF CHICAGO PRESS), 19, 1-4) BY COURTESY OF VICTOR HANDBOOK

FIG. 4.—A, ARM REGENERATION IN A SALAMANDER. B, 1-6 ARE REGENERATION STAGES, FOLLOWING AMPUTATION AT a: BLASTEMA AT 1 AND 2

Other organs can regenerate equally well, for instance, the tail, parts of the snout and eyes and parts of inner organs such as lungs and gonads. The regenerative capacity of salamander larvae and of young specimens exceeds even that of full-sized specimens. In the tailless Amphibia, the Anura (frogs, toads), the regenerative capacity is limited to larval stages, the tadpoles. They can readily regenerate a tail which is clipped at the tip or even near the base. The hindleg regeneration proceeds rapidly and efficiently in young tadpoles, but this capacity subsides when the larva approaches metamorphosis. Adult frogs do not regenerate limbs, contrary to a common belief. Usually, the stumps heal without regenerating. Recently, it has been found that if the arm of an adult frog is amputated and the wound surface is bathed repeatedly in a saturated sodium chloride solution, the stump will proceed to form a regenerate. However, the regenerated arm is never complete and normal. It is assumed that in untreated adult frogs the thick skin closes up rapidly over the wound surface and suppresses regeneration.

Reptilia.—Vertebrates higher than Amphibia have greatly reduced regenerative potentialities. The tail of a lizard is the only highly specialized structure in reptilians which can regenerate. The animal makes occasional use of this capacity. When captured by its tail, it shakes the tail off and leaves the foe behind with its token booty. Lizards with regenerated tails are occasionally encountered in the field. However, tail regenerates are

never complete; their inner structures are atypical. Amputated limbs of lizards do not regenerate.

Aves (Birds).—The regeneration of fragments of beaks has been reported for several birds. The periodic renewal of the plumage after each moult is a type of physiological regeneration, and the growth of a feather from a feather germ resembles other regenerative processes.

Mammalia.—These present numerous instances of physiological regeneration, but very little, if any, evidence for the regeneration of complex structures. The change of hair, of teeth and of red blood cells and the regeneration of antlers in deer illustrate physiological regeneration. Reparative regeneration, following an amputation, is limited to tissues, such as bone, muscle, skin or peripheral nerves. Whole organs can not be regenerated.

What general concepts can be derived from this survey? In the first place, it brings into proper relief a point which has been emphasized by students of regeneration since the early days, that there is a correlation between regeneration potentiality and level of organization; i.e., lower organisms have a high regenerative power and the latter decreases with increase in complexity. Mammals, including man, pay for their high organization with an almost complete loss of regenerative capacity. The relation between regenerative power and level of organization, however, holds only in a general way and breaks down in numerous special instances. For example, some planarian species have an exceptionally high regenerative power, but closely related species have none. The same holds for Annelida. The regenerative ability of the fishes is lower than that of the more highly organized tailed amphibians, the Urodela. The regeneration of the crystalline lens of the eye of salamanders is perfect in one species and entirely absent in a closely related species. These examples could be easily multiplied. They show that factors other than the general level of organization of the animal often play a decisive role.

It has also been asserted that since regeneration is a developmental process, embryos, larvae and young animals, in general, should be more readily capable of regeneration than adult stages of the same animal. This expectation is fulfilled in many instances, but again it is not a rigid rule. It is true that salamander larvae regenerate limbs and tails more rapidly and more perfectly than adults do, and lens regeneration in some salamander species is limited to larvae. Frog tadpoles can regenerate a hindlimb, but an adult frog can not. On the other hand, we have mentioned the seemingly paradoxical instance of the sea urchin and starfish larvae which do not regenerate, in contrast to the adults. The same holds for annelids and for tunicates. Again, factors other than age determine the limitation of regenerative power in these forms. Finally, one would expect that external organs and appendages which are readily exposed to injury and loss would show a higher regenerative capacity than inner organs. This, again, holds in a general way. However, several examples have been mentioned of the regeneration of inner organs which are rarely subject to injury during the normal course of life.

AUTOTOMY

A number of animals, when attacked and apprehended by a leg or tail, save their lives by casting off this appendage. The organ which is sacrificed can usually be restored by regeneration. This act of self-amputation is called autotomy. We find instances of autotomy in a number of different animal groups, such as Coelenterata, Mollusca, Echinodermata, Annelida, Arthropoda and others, although this means of escape is used only by a few representatives of these phyla and by no means by all of them. The only case of autotomy in vertebrates, and perhaps the best known of all, is that of the autotomy of the tail in lizards. Anybody who has tried to catch a lizard by its tail has had the experience of finding himself left with a wagging tail while the animal escaped; and one occasionally finds lizards in nature which show unmistakable signs of a regenerated tail. The facility with which the tail breaks off is astounding. This is because of a special structural adaptation. A breaking plane is prepared at the base of the tail along which it is severed when grasped. Several vertebrae

are split across their middle. The halves are held together by cartilage which ruptures readily. The regeneration usually begins at the breaking plane. The regenerated tail is not quite typical. It contains no vertebrae but merely a cartilaginous skeletal axis. The muscle and nerve distribution is likewise atypical. Nevertheless, such a regenerated tail can regenerate a second time.

Many Crustacea (crabs), insects and spiders have a similar device to facilitate autotomy, namely, a preformed breaking plane at the base of legs or antennae. The chitinous exoskeleton is soft and thin at certain levels, and the muscle arrangement expedites self-amputation. It is not always the same segment of the leg at which such a breaking plane is prepared, but the mechanism is apparently similar in all species. In the walking stick, all three pairs of legs are adapted for autotomy. Quite frequently, special care is taken to avoid an excessive loss of blood; the skin contracts over the wound and closes it off. A few other instances of autotomy may be mentioned: some actinians (sea anemones) let go of a tentacle when it is strongly stimulated; starfishes cast off an arm voluntarily and some annelids (segmented worms) can autotomize the hindmost body segments, and regenerate them subsequently.

One of the most startling instances of autotomy is the self-evisceration in holothurians (sea cucumbers). They belong to the Echinodermata and have the appearance of a cucumber-shaped, leathery bag. When strongly stimulated, they cast off their anterior ends, including tentacles, lantern and the water-vascular system and, at the same time, eviscerate through the anus the intestine and attached structures, such as gonads. The discarding of the inner organs is accomplished by strong muscle contraction. The nearly empty hull composed of skin and muscles is capable of regenerating the autotomized organs. *Thione*, which is found at the Atlantic seashore, can accomplish this feat within a month. The formation of the new intestine starts at the remnants of the mesenteries (linings of the body cavities) which were left behind. The body wall is instrumental in rebuilding the anterior organs. The gonads can be replaced only if fragments of them were left behind in the bag.

Under ordinary circumstances, the autotomy of legs, tails or antennae will occur when the animal is grasped by one of these appendages. In the ensuing struggle the mechanical pull or tension exerted on the preformed breaking plane will call forth the separation of the appendage. However, this is not the only way of eliciting autotomy. In many instances electrical shock, heat or chemical stimuli have the same effect. For instance, in the sea cucumber, *Thione*, autotomy can be induced experimentally by placing it in dilute ammonia water, or by electrical shocks which throw the body muscles into extreme convulsions. Increased water temperature has the same result in another form. In view of this observation, it is not surprising to find that some animals cast off a structure, seemingly spontaneously, but actually in response to adverse environmental conditions. For instance, some coelenterates autotomize a polyp head, and some holothurians eviscerate, when the water in which they live deteriorates.

There is only one step from this type of "spontaneous" autotomy to spontaneous fission for the purpose of asexual reproduction. For instance, certain starfishes and certain sea cucumbers break apart at more or less regular time intervals and the fragments regenerate a whole individual. Likewise, in certain annelids and flatworms, posterior parts of the body are constricted off and the fragments regenerate into new individuals. This performance has been established as a regular mode of reproduction. The close affinity of regeneration and reproduction in lower animals is thus again affirmed.

HETEROMORPHOSIS

A regenerate is ordinarily a replica of the original structure; but a number of cases are known in which regeneration is atypical in that either less or more than was lost is regenerated. Occasionally, the regenerate represents an organ entirely different from the one which it replaces. All forms of atypical regeneration are called heteromorphosis. The last mentioned category of heteromorphosis regenerations is called homocosis (William Bateson):

(1) *Incomplete regeneration* is frequent both in naturally occurring and in experimentally induced regeneration. Regenerated tails of lizards invariably show certain structural deficiencies, such as the absence of normal vertebrae. Regenerated salamander limbs frequently have a reduced number of digits or even greater deficiencies. Those of arthropods may have a reduced number of segments. Several species of annelids can regenerate only a limited number of head segments. If more are amputated, the total segment number of the worm after completed regeneration will be subnormal. Planarians occasionally regenerate a head with two fused eyes, or only one eye, or eyeless heads, instead of the normal head with two separate eyes. Such atypical head regenerates can be produced experimentally by exposing the regenerating animals to any one of a number of chemical agents which are known to impair developmental processes in a general, non-specific way.

(2) Among the *super-regenerations*, those of greatest interest are ones in which a single organ is replaced by a duplicated or multiple formation. Instances of such monstrosities have been observed in practically all regenerating animal forms, as, for instance, in hydranths of *Hydra* and of its marine relatives, in heads and tails of planarians and annelids, in tails of lizards and limbs or digits of amphibians and particularly frequently in appendages of arthropods. Double claws of crabs or lobsters, double legs and antennae of beetles and of other insects have been described. Starfishes with bifurcated arms and holothurians with duplicated body parts have also been observed. Triplicate appendages are most frequent in arthropods and occasionally found in other forms. They originate probably in most instances in the following way: a leg, or a claw or an antenna ruptures at a joint without breaking off completely. As a result, two wound surfaces are exposed, each of which begins to regenerate the distal parts. The two new formations, together with the persisting original structure, form the triple monstrosity. It was found that such triplicate structures follow a definite rule of symmetry relations (Bateson's rule): two adjacent components, namely, the middle one and one of the marginal components, are mirror images of each other, whereas the two marginal parts have the same symmetry pattern.

It is often difficult or impossible to decide whether double or triple monstrosities found in nature have been brought about by regeneration, or whether the duplication has already occurred in early embryonic development. Therefore, experimental methods were devised which permit us to study the origin of duplications by regeneration under controlled conditions. An expedient way of accomplishing this is to create a wound surface which will produce two separate blastemas instead of one. For instance, if the tail of a tadpole is amputated by two oblique cuts, in the form of an arrowhead (instead of making one transverse cut), then two blastemas and tails will grow out, each with its main axis perpendicular to the oblique, cut surface (Barfurth's rule). Multiple digits in salamander legs were produced in the same fashion, by making two oblique transections. Two-headed planarians (see fig. 5) can be obtained by making a longitudinal fission in the median plane through the anterior part of the animal, and a subsequent amputation of the two halves of the head. Each separate anterior body half then regenerates the missing lateral parts and in addition, a whole head at the anterior surface. By repeating this procedure, animals with multiple heads (up to ten) were obtained. In the same way, planarians with double tails can be produced experimentally.

(3) *Homoeosis*. This category of atypical regenerations includes all those instances in which the regenerate represents a structure different in type from the original. Homoeosis occurs mainly in arthropods. It is a characteristic of this phylum that most of the numerous body segments bear appendages which are of different types in different body regions (e.g., antennae, mandibles, claws, thoracic legs, abdominal appendages). In homoeosis, the appendage of one type substitutes for another type. A few examples may serve as illustrations: in crustaceans (crayfish, lobster, crab), a thoracic leg with claws was regenerated in place of a maxilliped; in other cases an abdominal leg was found in place of a thoracic leg. A leg may be regenerated in place of an antenna or of a mandible, and vice versa. An anterior wing of a butterfly or moth may replace a posterior wing. Of particular interest is the regeneration of an antenna in place of a stalked eye, which was observed in the marine decapod crustaceans of the genus *Palinurus*, *Palaeomon* and in others (fig. 6). This case was analyzed experimentally by Curt Harbst (University of Heidelberg). He discovered that if the optic ganglion which is located at the base of the eye stalk is removed along with the eye, an antenna grows out, but if the optic ganglion is left intact and the eye alone is amputated, a normal eye stalk and eye regenerate. The ganglion, then, determines the quality of the regenerate.

FROM HARBST, "REGENERATION" (COLUMBIA UNIVERSITY PRESS)

ORIGIN OF THE REGENERATION MATERIAL

Students of the process of regeneration have been chiefly concerned with two problems: the source of the material out of which the regenerates are formed, and the factors which determine the formation of typical organs and structures out of the raw material.

Early investigators were of the opinion that each tissue in the regenerate was formed by tissue outgrowth. For instance, in the regeneration of a salamander limb, the skeleton exposed at the amputation surface would regenerate skeleton, the muscle of the stump would give rise to new muscle. In other words, each tissue would be formed by tissue of its own kind. This idea was based on the assumption that differentiated tissues of the adult organism are highly specific and, therefore, not capable of transformation into other types of tissue; and, furthermore, that no other sources of regeneration material were available. Later investigations have led to a considerable modification of this point of view. Although some regenerated structures undoubtedly originate from their own kind, there is also some evidence to show that old tissue of the regeneration stump can differentiate into embryonic cell types and then redifferentiate into a structure different from what it had been before. This transformation is called "metaplasia." Furthermore, a third source of regeneration material has been discovered; in several animal groups certain types of reserve cells were found which are stored in different parts of the body and mobilized when the need for regeneration arises. We have, then, three modes of origin for regeneration material, and it is, of course, possible that several of them are combined in the same regeneration process. In many instances, it is difficult to distinguish between them, and our information concerning this entire problem is not far advanced.

Tissue Outgrowth.—The best example of the origin of a regenerating structure from its own kind is the nerve regeneration in vertebrates (see below, *Nerve Regeneration*). The nerves of a regenerated salamander limb or tail invariably originate by outgrowth of nerve fibres from the cut nerves of the amputation surface. The same holds for nerve regeneration following transection in higher vertebrates and in man. Also, the skin which closes

FIG. 5.—REGENERATION OF A DOUBLE HEAD IN PLANARIA. THE ANIMAL IS SPLIT ALONG LINES MED. AND TR. REGENERATED TISSUE IS UNSTIPPLED

FROM HARBURGER, "MANUAL OF EXPERIMENTAL EMBRYOLOGY" (UNIVERSITY OF CHICAGO PRESS)

over the amputation wound in salamanders and in many invertebrates is derived from the old skin of the stump, and it is retained as the covering of the outgrowing regenerate. The regeneration of bone, muscle, liver and other tissue in higher vertebrates and in man is likewise accomplished by remnants of their own kind. Salamanders have the remarkable capacity to regenerate an eye but are able to do so only if a fraction of the original eye tissue is left behind. These examples could easily be multiplied. Yet a glance at some of the regeneration phenomena in lower organisms convinces us that the principle that regenerated structures are derived from their own kind has only a limited applicability. A narrow transverse piece from the middle of a planarian body can regenerate a new individual, including eyes, a pharynx and the complex copulatory organs, although no traces of any of these structures were present in the original fragment (fig. 2). In the earthworm and in other annelids, the segments containing the gonads and other sex organs can be removed completely, yet the newly regenerated segments contain gonads. In the highly differentiated tunicates, any part of the body can regenerate many structures which it does not itself contain. Although these examples demonstrate beyond doubt that in lower organisms an organ or a structure can be formed anew, one would hesitate to attribute to vertebrates a similar versatility unless one were offered a crucial experimental proof. Such evidence has been provided for the skeleton regeneration of the salamander limb. At first, a long bone was carefully removed, as for instance the humerus, but the other tissues were left intact. After the wound had healed, the limb which merely lacked a humerus was amputated by a transverse cut in the upper arm. Although the amputation stump contained no bone, regeneration proceeded normally, and the regenerated distal part contained the normal skeletal elements. They originated by differentiation from the blastema, without direct contact with the old bone. A similar proof was given for the origin of the deep layer of the skin, the so-called dermis.

Reserve Cells.—Many invertebrates solve the problem of the formation of organs *de novo* with the help of "reserve cells" or "regeneration cells." These are cell types which have retained the characteristics and potentialities of embryonic cells; that is, they have not undergone a differentiation into specialized tissues. In hydra, and related coelenterates, the interstitial cells, a type of mesenchyme cells, are scattered throughout the body, except for the tentacles. According to many investigators, these cells assemble at a cut surface and become the chief, or exclusive, source of regeneration material. In a number of annelids, a type of particularly large cell has been found in different regions of the body. They are called "neoblasts" and play the same role as the interstitial cells of *Hydra*. They migrate toward the cut surface and there undergo a differentiation into different structures. They are apparently concerned with the new formation of muscles, of the pharynx, of blood vessels and of the walls and septa of the body cavities of regenerating segments, whereas the nervous system and some other structures originate by proliferation of the epidermis, and the new intestine is formed by outgrowth from the old intestine. Here we have an instance of a double source of regenerative material, from reserve cells and from old structures of the amputation surface. The exact share of both is still disputed. The Turbellaria (flatworms) contain similar formative or regeneration cells in the mesodermal parenchyma of the body. They belong in the same category with the interstitial cells and neoblasts. It was found that planarians with a high regenerative capacity contain more of these cells than do related species which have little regenerative power. Similar cell types have been described in Porifera (sponges) and Tunicates.

It is difficult to determine the origin of these reserve cells, and their share in regeneration, on the basis of microscopic studies alone. Despite much effort of a large number of careful investigators, many issues remain controversial. In this situation, the presentation of new evidence obtained by an entirely different technique was of great value. It was found that regeneration can be suppressed in both invertebrates and vertebrates, by radiation with X-rays, radium or other rays. A careful examination of the X-rayed tissues in hydra, flatworms and annelids showed that the

reserve cells or neoblasts are particularly sensitive to radiation and killed by a dosage which does not interfere seriously with the life processes of the animal as a whole. In this way it is possible to eliminate the reserve cells selectively without killing the animal. A close correlation was found between the loss of reserve cells and the loss of regenerative power; different dosages of irradiation resulted in a proportional reduction of reserve cells, and also a proportional reduction in regenerative capacity. These experiments seem to establish firmly the role of reserve cells in the regeneration of these forms.

Metaplasia.—The regeneration blastemas of amphibians which form limbs, tails or other regenerates are composed of undifferentiated cells which are densely packed and which give rise to most structures of the regenerate. Irradiation experiments have shown that in amphibians, in contrast to the above-mentioned invertebrates, the blastema cells are of local origin and do not migrate from other parts of the body. Careful histological studies have given satisfactory evidence that muscle and skeletal cells near the amputation surface can dedifferentiate and assume the appearance of undifferentiated, embryonic cells; and there is but little doubt that these cells contribute to the blastema material. It would be of a great general interest to know whether such cells redifferentiate into the same type of tissue from which they originated, or whether a true metaplasia of one type of tissue into a different one is possible. Another question remains to be solved: whether these dedifferentiated cells are the only source of material for the blastema. Connective tissue cells which are undifferentiated and resemble embryonic mesenchyme undoubtedly exist in adult amphibian organs. They may well have properties similar to the reserve cells of lower animals. It is possible that they are likewise mobilized for the formation of the blastema, and that the latter is, therefore, of a double origin.

A clear case of metaplasia occurs in the regeneration of the crystalline lens of salamander eyes. It is possible to remove the lens carefully with fine instruments without injuring the eye to any extent. If this is done, lens regeneration sets in at the upper margin of the iris. The iris is the pigmented part of the eye bordering on the pupil and adjacent to the lens. The first change which is observed in the iris following lens extirpation is the loss of pigment, that is, a process of dedifferentiation. Next, the two tissue layers which form the iris split, separate and expand at the rim to form a vesicle. This vesicle grows toward the pupil which it eventually fills. It differentiates into the transparent fibrous structure, characteristic of the lens, and becomes eventually detached from the iris. The regenerate is often indistinguishable from a normal lens.

Apart from its importance as an example of metaplasia, this case is of interest in another respect: the process of lens regeneration is entirely different from the origin of the lens in embryonic development. The embryonic lens is formed by an infolding of the epidermis overlying the embryonic eye and without participation of the iris. Evidently, the same end result can be achieved in two different ways, and the same organ can be derived from two different sources.

ANALYSIS

The Initial Stimulus.—An understanding of the regeneration process is based on a consideration of three aspects: the stimulus which starts regeneration, the source of the regeneration material and the organizing factors which direct the differentiation of this material into specific organs. The second question has been discussed above. Little information is available concerning the first problem. Ordinarily, an injury is necessary to start the process of regeneration. The trauma plays a role similar to that of fertilization in embryonic development. Undoubtedly, amputation upsets cellular physiological and biochemical equilibria at the wound surface, but we do not know which of these disturbances provides the essential stimulus. In the case of amphibian limb and tail regeneration, it was found that an initial phase of tissue breakdown near the amputation surface is the first reaction; it precedes blastema formation. As would be expected, the concentration of proteolytic enzymes, in particular cathepsin, is ex-

cessively high near the amputation surface and in the young blastema. How the histolytic processes prepare the ground for the synthetic processes is unknown.

A trauma is not necessary in all instances for the initiation of regeneration. In the case of lens regeneration in salamanders (see above, *Metaplasia*), the removal of the lens without injury to the upper iris activates the regeneration process in the latter. A series of ingenious experiments has shown that a chemical equilibrium exists between substances produced by the retina of the eye and substances produced by the lens. This equilibrium is upset by the removal of the lens and the ensuing change in the chemical milieu of the iris serves as the stimulus for its regeneration, in the place of a mechanical injury.

Determination: General.—The organizing factors for regeneration remain to be considered. Since we know little concerning the factors which govern regeneration by internal reconstitution (morphallaxis), the following discussion will be limited to regenerations which proceed by way of blastemas (epimorphosis). Limb and tail regenerations in urodelean amphibians have been the objects of the most intensive analysis of these factors.

In a causal analytical approach which tries to penetrate more deeply into the nature of regeneration than a pure description can do, problems of the following kind become pertinent. What are the potentialities and properties of the blastema? In which way, and by which agents, is its destiny determined? Where do the factors reside which bring it about that one blastema forms a limb and another one forms a tail? This type of question has been suggested to the student of regeneration by the experimental embryologist who has analyzed the embryonic process from a similar point of view (for the following discussion see *EXPERIMENTAL EMBRYOLOGY*). It was found that, at least in amphibians and other vertebrates and in some invertebrate embryos, early embryonic cells are relatively indifferent for a considerable period, and pluripotent, that is, capable of differentiation (*q.v.*) along any one of several different lines. Their potentialities become gradually limited and their final fates determined by interaction with so-called "inductors," by hormonal influences and by other agents. We shall see that in all probability the same holds for regeneration blastemas. This process of gradual fixation of the final fate of cell groups is called "determination." Whereas regeneration blastemas, as well as embryonic primordia, receive their essential and immediate determining influences from factors residing within the organism, the external milieu can modify the direction of regeneration and of developmental processes. This holds particularly for lower invertebrates, such as coelenterates and planarians. The influence of the chemical environment, of temperature and so forth on the regeneration process can be considered as subsidiary determining factors.

Experimental embryology has devised the methods and techniques for the analysis of such problems. It is obvious that causal-analytical questions concerning determination can be answered only by experimental methods. The factors of the external milieu can be studied relatively easily in controlled experiments, in which one factor is varied quantitatively, and all others are kept constant. The methods of microsurgery which have been devised in experimental embryology for the study of internal factors were found to be applicable to regeneration as well. They are: "extirpation," that is, the complete removal of an organ or structure for the purpose of studying the effect of its absence on adjacent or other parts; "transplantation" of structures from one part of the body to the other, for the purpose of studying tissue interactions, and "isolation" in tissue culture or otherwise, for the purpose of studying the inherent potentialities of an isolate.

The Potentialities of the Blastema.—The following discussion refers to regeneration in amphibians. A number of experiments support the view that the early limb and tail blastemas are relatively indifferent, or undetermined, during the earliest phase of their growth. To prove this, it is necessary to show that they can be induced to form structures which they would not form in the normal course of their development; in other words, that they are pluripotent. If a young forelimb blastema, a few days old, without the underlying stump parts, is transplanted onto a

hindlimb amputation stump, it forms a hindlimb. If the same experiment is done with a forelimb blastema nine days old or older, it forms a forelimb. The two experiments demonstrate that the blastema is relatively indifferent during the first week, whereupon its fate becomes irreversibly fixed. Other experiments give further proof of the pluripotency of young tail blastemas. They can be induced to form structures entirely foreign to their normal fate, such as a crystalline lens or an ear vesicle, if they are brought under the influence of the so-called inductors for these structures. Finally, the occurrence of duplications on a single regeneration stump illustrates the same point of relative indeterminacy of the young blastemas.

Regeneration Fields.—These experiments suggest that the decisive factors for the determination of the blastemas must be sought outside of the blastemas themselves. The following experiments show that they reside in the amputation stump. If a forelimb is transplanted to the flank between the fore- and hindlimb position and then amputated in its middle, the stump regenerates a forelimb. Even a transplanted small slice of a forelimb amputation stump suffices to bring about forelimb regeneration at a foreign location. Similar results were obtained with hindlimb and tail transplants. One may ask: what is the extent of the areas which contain the limb or tail determining agents? If a limb is amputated at its base, the shoulder or pelvic region is still capable of restoring the limb. However, if the girdles are also extirpated, regeneration fails to occur. The capacity for limb regeneration is obviously limited to a well-circumscribed area. The same was shown for tail and snout regeneration. Likewise, an eye or a gill can be regenerated only if a remnant of these organs is left behind. An area which is capable of organizing the regeneration of a specific organ is called a "field-district," and the organizing factors within such a district constitute its "field." We speak of a limb, or tail, regeneration field, etc. Paul Weiss (University of Chicago) and E. Guyonot (Geneva university) are mainly responsible for the development of the regeneration-field concept. One of its theoretical implications is this: all experiments show clearly that it is not the whole animal which regenerates a limb or an eye, but it is the limb or eye regeneration-field which restores its lost parts. It would, therefore, be misleading to consider regeneration merely from the teleological point of view.

The field concept has been fruitfully applied to embryonic development. More or less definitely delimited embryonic areas which contain the factors for the determination of a specific organ, such as ear or eye, are called embryonic or "morphogenetic" fields. In some instances, an embryonic field is carried over into adult stages as a regeneration field.

One of the outstanding characteristics of a field is that it is a unit, or a whole, and not merely the sum of the cellular materials of which it is composed. This property is illustrated best in those instances in which a field is split in half, whereupon each half gives rise to a whole organ. For instance, the amputation stump of a limb can be split lengthwise, and one lateral half removed. The remaining half cross section of the stump then regenerates a whole foot rather than a half foot. All double and multiple regenerations illustrate the same point. Likewise, two blastemas which are fused together and implanted on one stump give rise to one harmonious limb. Generally speaking, the field with its organizing capacities remains undisturbed if the cellular material which it controls under normal circumstances is diminished or enlarged. The unit-character of the field finds its clearest manifestation in these regulative properties.

The Role of the Nervous System.—It has been established beyond doubt that the presence of peripheral nerves is necessary for amphibian limb regeneration. The experiments which prove this are usually set up as follows: the limb nerves are transected at the shoulder or pelvic region, and the limb is amputated more distally, for instance at the elbow, or knee, respectively. Limb regeneration is then inhibited. However, the nerves have the capacity to regenerate, and as soon as the regenerated nerve fibres have reached the amputation surface, the regeneration of the limb begins. If the nerve regeneration is prevented by repeated nerve transections at the base of the limb, then the limb regen-

eration is not only blocked permanently but the amputation stump, including its skeleton and musculature, undergoes regression, and the entire limb is eventually resorbed. These and similar experiences lead to the belief that it is the function of the nervous system to stop the resorption at the amputation stump, which is the first phase in the regeneration process, and to promote the subsequent synthetic activities. At any rate, the role of the nervous system in regeneration is not that of an inductor of specific structural characters but of a trophic agent. The question as to which component of the peripheral nerves, sensory, motor or sympathetic, plays the essential role has led to a great amount of experimental work since the beginning of the 20th century, but has not been settled. It is possible that not any one specific component but merely a certain quantity of nerve fibre material is required for regeneration.

The nervous system is likewise essential in the regeneration of some invertebrates, but dispensable in others. The regeneration of the earthworm head seems to be dependent on the presence of the ventral nerve cord at the amputation surface. The influence of the nervous system on eye regeneration in the marine decapod crustaceans was mentioned above (under homeosis). If the eye and eye stalk are amputated but the eye ganglion at its base is left intact, then a normal eye regenerates. If the eye ganglion is also removed, then an antenna is formed instead of an eye (fig. 6). However, this case can not be considered as representative of all arthropod regenerations.

For instance, in the praying mantis, regenerations of normal legs and of normal antennae were observed after removal of their ganglia, and similar instances of regeneration in the absence of innervation are known to occur in other arthropods.

Polarity; Polar Heteromorphosis.—Polarity refers to the regional differences along the main axis of an organism; it is clearly expressed in head formation at one end and tail formation at the other. It is also expressed in the formation of the tentacle-bearing polyp (hydranth) at the distal end of the stem of *Hydra* and its marine relatives and of a stolon at the other (fig. 8). Polarity is ordinarily retained in regeneration. For instance, a transverse piece of a planarian from the middle of the body regenerates a head at the anterior cut surface and a tail at the posterior amputation surface. A stem piece of *Hydra*, or of any other coelenterate, regenerates a hydranth at its distal surface. However, reversal of polarity does occur occasionally, as for instance in the formation of two heads on both ends of a regenerating piece of planarian (fig. 7) or of two hydranths at both ends of a stem piece of the marine coelenterates, *Tubularia* and *Corymorpha*. Instances of polarity reversal are called polar heteromorphosis. We shall see that they can be produced experimentally.

Gradient Theory.—These atypical cases bring into focus the question of the nature and determination of polarity. Older theories which explained polarity and its maintenance in regeneration on the basis of different concentrations at different levels of head- or tail-determining substances or stuffs have been completely abandoned. It is generally recognized that a dynamic concept of polarity is necessary to explain such fundamental aspects as this: that the same body level of a planarian regenerates a tail if it happens to be the posterior cut surface of an anterior piece, or a head, if it happens to be the anterior level of a posterior piece. The gradient theory of C. M. Child (formerly of the University of Chicago) offers the most satisfactory dynamic con-

cept of polarization. According to this theory, the structural polarity is the manifestation of a gradation of physiological or metabolic activities which are highest at the anterior and lowest at the posterior end. The existence of axial physiological gradients (g.v.) has been demonstrated by several methods, as, for instance, by the differential disintegration of animals when exposed to toxic agents. According to this theory, a head, or hydranth, regenerates at that region of an isolated piece which has the highest metabolic activity, and the tail, or stolon, at the region of lowest activity. Since in a transverse piece of a planarian the cut surface which was originally nearest the head has a higher activity than any other level of the piece, it will be the one which regenerates a head. In other words, the fate of a regeneration blastema is not determined by specific structural conditions at the cut surface but by its relative position in the whole regenerating system. The polar heteromorphoses, which occur predominantly in very short pieces (fig. 7), are explained by the assumption that in such short pieces no differential, or gradient, is established between the two surfaces, and that their metabolic levels are equally high.

The concepts of "physiological dominance" and of "physiological subordination" are an important corollary to the axial gradient theory. It is postulated that the region of highest metabolic activity, apart from forming head, or hydranth, suppresses at the same time the head or hydranth formation in any other part of the regenerating system; it sets itself up as a "dominant region."

One of many experiments which demonstrate "physiological dominance" may illustrate this concept (fig. 8). In the marine coelenterate, *Tubularia*, a piece of the stem was isolated and the distal amputation surface which normally would have regenerated the hydranth was separated from the rest of the piece by a tight ligature. As a result, the other end of the stem which was in this way released from the inhibiting effect of the dominant region, set itself up as a new dominant region and formed a hydranth. In this way the original polarity was reversed and a polar heteromorphosis produced. The ligature experiment has made it possible to analyze dominance quantitatively; it has led to an interpretation of the dominance relation in terms of competition for available substances (see W. G. Barth, 1940). In other experiments, it was possible to obliterate the polarity of a stem piece completely by exposing it to adverse environmental conditions. As a result, it undergoes involution and forms a spherical aggregate of cells. In the subsequent regeneration of such amorphous masses, a new polarity is developed which has no relation to the original polarity. In accordance with Child's concepts, it should be possible to control the polarization of such fragments by raising the metabolic activity locally, which would make this particular region the dominant hydranth-forming region. This can be done in the following way: pieces of *Tubularia* and *Corymorpha* are sensitive to oxygen tensions, and free access to oxygen is a necessary condition for their regeneration. If depolarized aggregates are placed on the bottom of a dish, the new hydranth is formed at the contact-free surface. According to Child, those cells which are freely exposed to sea water are raised to the relatively highest level of metabolic activity and, consequently, set themselves up as hydranth-forming, dominant regions. Many other phenomena of regeneration and asexual reproduction, particularly in lower animals, have been interpreted in terms of the gradient theory. For an exhaustive presentation

FIG. 8.—EXPERIMENTAL REVERSAL OF POLARITY IN THE MARINE POLYP, TUBULARIA. A PIECE 1-2 (a) REGENERATES NORMALLY A HYDRANTH AT 1 AND A STOLON AT 2. (b) IF A LIGATURE IS MADE AT 1, A HYDRANTH REGENERATES AT 2 (c).

concept of polarity is necessary to explain such fundamental aspects as this: that the same body level of a planarian regenerates a tail if it happens to be the posterior cut surface of an anterior piece, or a head, if it happens to be the anterior level of a posterior piece. The gradient theory of C. M. Child (formerly of the University of Chicago) offers the most satisfactory dynamic con-

cept of polarization. According to this theory, the structural polarity is the manifestation of a gradation of physiological or metabolic activities which are highest at the anterior and lowest at the posterior end. The existence of axial physiological gradients (g.v.) has been demonstrated by several methods, as, for instance, by the differential disintegration of animals when exposed to toxic agents. According to this theory, a head, or hydranth, regenerates at that region of an isolated piece which has the highest metabolic activity, and the tail, or stolon, at the region of lowest activity. Since in a transverse piece of a planarian the cut surface which was originally nearest the head has a higher activity than any other level of the piece, it will be the one which regenerates a head. In other words, the fate of a regeneration blastema is not determined by specific structural conditions at the cut surface but by its relative position in the whole regenerating system. The polar heteromorphoses, which occur predominantly in very short pieces (fig. 7), are explained by the assumption that in such short pieces no differential, or gradient, is established between the two surfaces, and that their metabolic levels are equally high.

of the subject see *See* Child, 1941.

NERVE REGENERATION

The process of nerve regeneration is of great practical importance in medicine and deserves special consideration. It has been studied extensively by biologists and clinicians, in higher animals and in the human being. World Wars I and II have given additional incentive to its exploration.

It should be realized that nerve regeneration is limited to the peripheral nerves; the central nervous system, including brain, spinal cord and ganglia can not restore lost nerve cells.

For an understanding of nerve regeneration, it is necessary to give a brief account of the structure of peripheral nerves. They are composed of bundles of nerve fibres held together by connective tissue. Each nerve fibre has a rather complex structure. Its most essential part, the central axon, is a delicate protoplasmic thread which is spun out in early embryonic development by one of the nerve cells located in the central nervous system. It terminates in an effector (muscle, gland) or in a sense organ. The axon remains part of the cell body from which it originated. It is dependent in its metabolic activities on a continuity with its cell body and nucleus, and any part of the axon which is cut off from it degenerates. In the case of accidental or experimental severance of a peripheral nerve, all portions of the axons distal, or peripheral, to the transection are broken down. Nerve regeneration is accompanied by a revival of growth activities at the proximal, or central, ends of the severed axons which retained their connections with their cell bodies. Most peripheral axons are covered by a noncellular myelin sheath which gives them a whitish, glistening appearance and all of them are surrounded by an outer sheath, the so-called Schwann sheath, formed by delicate, nucleated cells. In myelinated fibres the Schwann sheath cells cling tightly to the surface of the myelin sheath, but at times they are capable of migration, and they play an important role in regeneration. The term "nerve fibre" is applied to the axon and its sheaths.

If a nerve is severed by a cut or an injury, its first reaction is a degeneration process which sets in at the proximal as well as at the distal stump. However, degeneration at the proximal end is limited to a short stretch near the amputation surface and is soon superseded by regenerative processes, whereas the entire distal nerve part breaks down eventually, including the nerve endings. Degeneration results in a complete disintegration of the axons and of their myelin sheaths; the debris are gradually removed by macrophages. The cells of the Schwann sheath are not only not affected by this degeneration but, on the contrary, stimulated to new activities. They become instrumental in preparing the pathways for the newly outgrowing nerve fibres both in the gap, or scar, and along the entire length of the peripheral nerve stump. Shortly after nerve transection, they begin to proliferate abundantly, and large numbers of them migrate from the two cut ends into the gap. Together with connective tissue cells (fibroblasts), they become arranged in more or less parallel strands, through which the regenerating fibres use later on as tracks to reach the distal stump. At the same time, the Schwann cells within the distal stump undergo an equally active proliferation and line up in rows to form long protoplasmic strands, the so-called "bands of Büngner" (after O. von Büngner, who discovered them in 1891). These bands eventually fill the spaces formerly occupied by the degenerated axons and myelin sheaths. They form an ideal substrate and guiding structure for the regenerating nerve axons, which will subsequently enter the distal stump. All changes in the latter, up to this point, are called "Wallerian degeneration" (after A. Waller, who gave the first classical description of this process, in 1852). This term is somewhat misleading since it includes, in its present connotation, not only the degenerative phase but also the simultaneous formation of the bands of Büngner, which is a decidedly constructive process preparatory to reinnervation.

The regeneration process in the true sense of the word, namely, the sprouting of the axons from the proximal nerve ends, starts soon after nerve severance. The cut ends branch profusely and begin to traverse the gap. The course of these fibres is at first rather irregular, but under favourable conditions, parallel strands of regenerating fibres may reach the distal end of the gap as early as 15 days after transection. How do the fibres find the distal stump? Why are they not lost in the scar? It has been claimed repeatedly that the peripheral stump attracts the fibres by a chemical agent (neurotropism), but all experimental evidence is against such chemotropism; galvanotropism is likewise ruled out as a guiding mechanism. The view which is rather generally adopted is that the nerve fibres are not directed by agents acting at a distance but that they merely follow tracks which they find in the substrate or in the bands of Büngner and to which they cling ("contact guidance," P. Weiss). The Schwann sheath cells and fibroblasts, which are aligned in parallel strands in the scar and which form a bridge between the two nerve ends, supply a suitable track system for the sprouting nerves. Once the peripheral stump is reached, the bands of Büngner with their linear orientation provide an ideal guiding structure all the way through the peripheral tract to the end organs. The first fibres which reach the periphery are thin, and few in number. Before a regenerated nerve is able to carry impulses effectively, the fibres must increase in thickness and in numbers, and they must become myelinated. In man, this process takes several months, depending, of course, on the distance of the end organ from the wound.

It is evident that nerve regeneration faces its greatest hazard in the crossing of the gap, or scar. Functional repair can be successful only if the gap is not too extensive and if the out-growing nerves find in the scar a substrate with longitudinal orientation of cells or micelles. It is at this point that the surgeon can lend a helping hand. To reduce the hazards, nerve ends are usually connected with sutures, or by a so-called "tubulation," that is, by fitting the ends together with a sleeve made from a piece of artery or of other organic or inorganic materials. Larger gaps are sometimes closed by an autoplasmic nerve transplant (that is, a piece of another nerve from the same individual). The transplanted piece supplies, of course, merely a suitable guiding structure and not the nerve material proper. None of these methods is ideal, but a continued experimental analysis of the mechanism of nerve regeneration will undoubtedly bring about advances in the surgery of nerve repair.

REGENERATIVE OR RECUPERATIVE FURNACE: see FURNACE, METALLURGICAL.

REGENSBURG (RATISBON), a city and episcopal see of Germany, in the Land of Bavaria, and the capital of the government district of the Upper Palatinate. Pop. (1939) 97,924. It is situated on the right bank of the Danube, opposite the influx of the Regen, 86 mi. by rail N.E. from Munich, and 60 mi. S.E. of Nurnberg. The pre-Roman settlement of *Radespona* was chosen by the Romans, who named it *Castra Regina*, as the centre of their power on the upper Danube. It afterward became the seat of the dukes of Bavaria and was the focus from which Christianity spread over southern Germany. St. Emmeran founded an abbey there in the middle of the 7th century, and St. Boniface established the bishopric about 100 years later. Regensburg acquired the freedom of the empire in the 13th century, and was for a time the most flourishing city in southern Germany. It became the chief seat of the trade with India and the Levant, and the boatmen of Regensburg are frequently heard of as expediting the journeys of the crusaders. Numerous imperial diets were held there in the middle ages, and after 1663 it became the regular place of meeting of that body. The Reformation found only temporary acceptance at Regensburg and was met by a counter-reformation inspired by the Jesuits. Before this period the city had almost wholly lost its commercial importance because of the changes in the great highways of trade. Regensburg is said to have suffered in all no fewer than 17 sieges. In 1810 the town and bishopric were ceded to Bavaria. In 1809 the French reduced a great part of the city to ashes.

Across the river is Stadt-am-Hof, connected with Regensburg by a stone bridge of the 12th century. One of the most characteristic features in its architecture is the number of strong looped towers attached to the more ancient dwellings.

The cathedral, though small, is an interesting example of pure German Gothic. It was founded in 1275 and completed in 1634, with the exception of the towers, which were finished in 1869. Adjoining the cloisters are two chapels of earlier date than the cathedral itself, one of which, known as the "old cathedral," goes back perhaps to the 8th century. The church of St. James—also called Schottenkirche—a plain Romanesque basilica of the 12th century, derives its name from the monastery of Irish Benedictines ("Scotti") to which it was attached. The old parish church of St. Ulrich is a good example of the Transition style of the 13th century. Examples of the Romanesque basilica style are the church of Obermünster, dating from 1010, and the abbey church of St. Emmeran, built in the 13th century, and remarkable as one of the few German churches with a detached belfry. The cloisters of the ancient abbey, one of the oldest in Germany, are still in fair preservation. In 1809 the conventual buildings were converted into a palace for the prince of Thurn and Taxis. The town hall, dating in part from the 14th century, contains the rooms occupied by the imperial diet from 1663 to 1806. Among the chief manufactures are pottery, parquet flooring,

murdered at Lausanne. The last survivor of the regicides was probably Edmund Ludlow, who died at Vevey in 1692.

BIBLIOGRAPHY.—Ludlow's *Memoirs*, edited by C. H. Firth (Oxford, 1894), give interesting details about the regicides in exile. See also D. Masson, *Life of Milton*, vol. vi. (1880), and M. Noble, *Lives of the English Regicides* (1798); L. E. Welles, *History of the Regicides* (1907).

REGILLUS, an ancient lake of Latium, Italy, famous in the legendary history of Rome as the lake in the neighbourhood of which occurred (496 B.C.) the battle which finally decided the hegemony of Rome in Latium. Of the various sites proposed, the best is Pantano Secco, some 2 m. N. of Frascati.

REGINA, the capital city of the province of Saskatchewan, Canada, situated at $104^{\circ} 36' W.$ and $50^{\circ} 27' N.$, and 357 mi. W. of Winnipeg. Pop. (1951), 69,928. After the Canadian Pacific railway was completed in 1885, the necessity for a place of government on the railway line pressed itself upon the federal government. The Northwest Territories were but little settled then, but a central position on the prairies was necessary, where the mounted police might be stationed and where the numerous Indian bands might be easily reached. The minister of the interior at Ottawa, afterward Gov. Edgar Dewdney, chose this spot, and for a number of years Regina was the seat of the territorial government. The governor took up his abode on the adjoining plain, and the North-West council met each year, with a show of constitutional government about it. On the formation of the province of Saskatchewan in 1905 the choice of capital was left to the first legislature of the province. Prince Albert, Moose Jaw and Saskatoon all advanced claims, but Regina was decided on as the capital.

The city has a large distributing trade and is the central market for an agricultural region. It is on the Canadian Pacific and Canadian National railways, and has several radiating lines. There are many mills, banks, wholesale houses and factories, including a large oil refinery. Regina is the western headquarters of the Royal Canadian Mounted Police.

REGINON, or **REGINO DE PRÜM**, mediaeval chronicler, was born at Altrip near Spire, and was educated in the monastery of Prüm. Here he became a monk, and in 892, just after the monastery had been sacked by the Danes, he was chosen abbot. In 899, however, he was deprived of this position and he went to Trier, where he was appointed abbot of St. Martin's. He died in 915, and was buried in the abbey of St. Maximin at Trier, his tomb being discovered there in 1831.

Reginon wrote a *Chronicon*, dedicated to Adalbero, bishop of Augsburg (d. 909), which deals with the history of the world from the commencement of the Christian era to 906, especially with the affairs in Lorraine. The chronicle was first published at Mainz in 1521; another edition is in Band I. of the *Monumenta Germaniae historica. Scriptores* (1826); the best is the one edited by F. Kurze (Hanover, 1890); German trans. by W. Wattenbach (Leipzig, 1890). Reginon also drew up at the request of his patron, Rabod, archbishop of Trier (d. 915), a collection of canons, *Libri duo de synodalihus causis et disciplinis ecclesiasticis*; this is published in Migne's *Patrol. Lat.* t. 132.

See H. Ermisch, *Die Chronik des Regino bis 813* (Göttingen, 1872); P. Schulz, *Die Glaubwürdigkeit des Abtes Regino von Prüm* (Hamburg, 1894); C. Wawra, *Die Reginone Prumensis* (Breslau, 1901).

REGIOMONTANUS (1436-1476), German astronomer, was born at Königsberg in Franconia on June 6, 1436. His name originally was Johann Müller, but he called himself, from his birthplace, Joh. de Montegio, an appellation which became modified into Regiomontanus. At Vienna, from 1452, he was the pupil and associate of George Purbach (1423-1496), and they jointly undertook a reform of astronomy rendered necessary by the errors they detected in the Alphonsine Tables. In this they were much hindered by the lack of correct translations of Ptolemy's works; and in 1462 Regiomontanus accompanied Cardinal Bessarion to Italy to study a copy of the *Almagest*. He rapidly mastered Greek at Rome and Ferrara, lectured on Alfraganus at Padua, and completed at Venice in 1463 Purbach's *Epitome in Cl. Ptolemaei magnam compositionem* (printed at Venice in 1496), and his own *De Triangulis* (Nuremberg, 1533), a treatise on trigonometry. In 1468 he returned to Vienna, and was thence summoned to Buda by Matthias Corvinus, king of Hungary, for the purpose of collating Greek manuscripts. He also finished his *Tabulae Direc-*

tionum (Nuremberg, 1475), essentially an astrological work, but containing a valuable table of tangents.

In 1471 Regiomontanus settled at Nuremberg. Bernhard Walther, a rich patrician, became his pupil and patron; and they together equipped the first European observatory, for which Regiomontanus himself constructed instruments of an improved type (described in his posthumous *Scripta*, Nuremberg, 1544). His observations of the great (Halley's) comet of 1472 supplied the basis of modern cometary astronomy. At a printing-press established in Walther's house by Regiomontanus, Purbach's *Theorica planetarum novae* was published in 1472 or 1473; a series of popular calendars issued from it, and in 1474 a volume of *Ephemerides* calculated by Regiomontanus for thirty-two years (1474-1506), in which the method of "lunar distances," for determining the longitude at sea, was recommended and explained. In 1477 Regiomontanus was summoned to Rome by Pope Sixtus IV., to aid in the reform of the calendar; and there he died on July 6, 1476.

See P. Gassendi, *Vita Jo. Regiomontani* (Parisii, 1654); and the general histories of astronomy.

REGIONAL PLANNING, a term used by community planners, engineers and geographers to describe a comprehensive ordering of the natural resources of a community, its material equipment and its population for the purpose of laying a sound physical basis for the "good life." In America the term has also been used to describe plans for city extension over wide metropolitan areas; this type of planning should properly be called metropolitan planning. Regional planning involves the development of cities and countryside, of industries and natural resources, as part of a regional whole.

The programme of regional planning has grown out of a multitude of fresh initiatives; the activities of foresters and conservationists with forest working plans, of engineers with water power plans, of municipal engineers with plans for city extensions and parkways, and finally, of a great school of regional geographers, who, under Vidal de la Blache in France, Herbertson in England, Fenneman, Smith and others in the United States, have established the region as a definite unit, with its special individuality of geologic formation, climate, vegetation, landscape and human culture. The method of the regional plan can perhaps best be grasped by considering its simpler prototype, that which covers but a single aspect of regional life. Take an actual forest working plan for an area in the State of Washington, between the Cascade range and Puget sound: it is about the size of Rhode Island. Except for the mountain barrens and narrow strips of agricultural land along the rivers, the whole region is under forest. The plan divides this area into six "cutting-blocks," each block to be cut within a ten year period and the logs hauled to a central saw mill. When the last block has been cut over the first is ready to be cut again. The central mill and the houses provided for its working force are permanent fixtures.

This plan brings out the essential characteristics of every regional plan, whether specialized or comprehensive. (1) It deals with a geographic area; (2) it surveys that area and discovers its natural characteristics and resources; (3) it suggests a method of conserving its resources and developing its economic life; (4) it erects relatively permanent seats of human habitation, with all the social facilities that derive from such stability. Lacking such a plan and such a public policy, current commercial methods of exploitation would cut over the entire area in one operation, would provide only temporary employment and temporary habitations, would make no provision for natural reforestation, and would, as a result, permit the soil of the timber-mined area to be washed away, degrading the whole region and making further human activity difficult, if not impossible in it.

The Means to an End.—A regional plan, if it is really a plan and not a description, deals not only with a geographic area but with a force or "flow" or group of activities taking place within it. This flow may consist of water or electricity or commodities like lumber, wheat, dairy produce, manufactured articles—some product required for human sustenance. The flow may also be that of population; this includes industrial plant and social institutions—schools, libraries, churches, colleges, museums, hospitals

—in short, a flow of civilization. We usually regard these things as static; actually, they are always in motion, improving, deteriorating, changing their position, if not from year to year, then from decade to decade. Regional planning would direct and modify these changes to the advantage of the whole community, instead of simply letting them "happen." A comprehensive regional plan involves not merely the forces of man's industrial life but his cultural activities as well; for plans that concern themselves solely with the means of life are in danger of defeating man's cultural activities, which express his aims or objectives. In contrast to the view of industrial production almost universally accepted during the 19th century, regional planning recognizes that the means must be subordinate to the ends. Thus, in utilizing sites along a river, the regional planner may reserve for recreation a spot that would ordinarily be dedicated to heavy manufacturing; or between two possible types of industry, he may select that which has a higher civilization-value. Regional planning, following Ruskin, recognizes as the ultimate product of industry not money or commodities but human life. Briefly, regional planning deals with the ecology of the human community. Just as plant ecology treats of the climate, soil, the plant and insect partnerships necessary to the existence of a species of plants, so regional planning deals with the climate, vegetation, minerals, power resources, landscape, economic and social institutions necessary to a flourishing human community. It is not an effort to make a region self-subsistent; it is an attempt to bring it into the highest state of economic and human cultivation. No region is a self-contained unit. Except for islands and isolated mountain areas, there are no self-contained units even in the narrow geographic sense, whilst economically and culturally no region has existed without contact with other regions. Inter-regional relationships are just as important as internal ones, and of as much concern to the regional planner. Thus it has been pointed out that the only fundamental solution of New York's congestion of population and traffic involves a redistribution of the flow of commodities through the Atlantic ports, decreasing the share that now falls to New York, and redistributing part of New York's growing population in regional cities outside the immediate metropolitan area. Such a programme was partly sketched out in the final report of the New York State Housing and Regional Planning commission (1926).

Aspects.—In the countries where there is regional planning one aspect or another has usually been dominant, although regional planning involves every aspect of a region's life. In France, for example, the necessity for political administrative units that bear some relation to economics, history and geography has made the political side dominant; similar considerations have governed the drawing up of new governmental units in Siberia. Regional survey brings out the arbitrary nature of a great many political boundaries, and suggests the possibility of re-drawing them, or of co-operatively ignoring them, as in the constitution of the New York-New Jersey port authority. Economically, regional planning seeks the fullest development of local resources and skills, without the extravagant waste and degradation that accompanied this process in the past; in America this aspect of regional planning has been uppermost in the work of foresters and conservationists like Gifford Pinchot and Liberty Hyde Bailey. Socially, regional planning attempts to curb the growth of metropolitan slums and to create independent cities in more effective relationship with nature and industry and to take care of further increments of population: in England, the garden city movement, which has built Letchworth and Welwyn, has emphasized this side of regional planning. In reports on the Deeside and the Doncaster districts in England, and the newly found coal-areas in Kent, as well as in the final report of the New York State Housing and Regional Planning commission, these various aims have been co-ordinated and focussed. Regional rather than metropolitan development has been aided by motor transport and the aeroplane, by the radio, telephone, and giant power; and regional planning tends to make the fullest use of these. Similar reports and surveys have been made for the Ruhr district in Germany, for the French Alps, and, on a smaller scale, for agricultural communities in the Caucasus.

Among the precursors and intellectual preceptors of the modern

regional planning movement, one must note Auguste Comte and Frédéric Le Play in political decentralization, Henry Thoreau in philosophy, George Perkins Marsh, author of *The Earth as Modified by Human Action*, Reclus, Ratzel and Shaler in geography, Kropotkin in economics, and Patrick Geddes, whose social studies and technical initiatives as city planner have touched every part of it. The first conception of dealing with the administration of modern utilities like electricity on a regional, rather than a national or local scale, was embodied in a Fabian pamphlet in the "New Heptarchy Series" on *Municipalisation by Provinces*; the first definitive project for a regional city was that issued by Sir Ebenezer Howard in *Tomorrow* (see GARDEN CITIES).

REGIUM, a city of the territory of the Brutti in South Italy, on the east side of the strait between Italy and Sicily (see REGGIO DI CALABRIA). A colony, mainly of Chalcidians, partly of Messenians from the Peloponnese, settled at Regium in the 8th century B.C. About 494 B.C. Anaxilas, a member of the Messenian party, made himself master of Regium (apparently with the help of the Samians: see MESSINA) and about 488 joined with them in occupying Zancle (Messina). In 433 Regium made a treaty with Athens, and in 427 joined the Athenians against Syracuse, but in 415 it remained neutral. An attack which it made on Dionysius I of Syracuse in 399 was the beginning of a great struggle which in 387 resulted in its complete destruction and the dispersion of its inhabitants as slaves; but it soon recovered its prosperity. In 280, Pyrrhus invaded Italy, the Regines admitted within their walls a Roman garrison of Campanian troops; these mercenaries revolted, massacred the male citizens, and held the city till in 270 they were besieged and put to death by the Roman consul Genucius. The city remained faithful to Rome throughout the Punic wars, and Hannibal never succeeded in taking it.

It took the name Regium Iulium under Octavius (Augustus); and the pedestal of a statue erected in his honour (as Augustus) has been found there. It continued to be a Greek city even under the empire. Toward the end of the empire it was made the chief city of the Brutti.

See P. Larizza, *Rhegium Chalcidense* (Rome, 1905); Orsi in *Notizie degli scavi*, 1902, 151 sqq.

REGIUM DONUM or ROYAL GIFT, an annual grant formerly made from the public funds to Presbyterian and other Nonconformist ministers in Great Britain and Ireland. In 1690 William III. made a grant of £1,200 a year to the Presbyterian ministers in Ireland as a reward for their services during his struggle with James II. Owing to the opposition of the Irish House of Lords the money was not paid in 1711 and some subsequent years, but it was revived in 1715 by George I., who increased the amount to £2,000 a year. Further additions were made in 1784 and in 1792, and in 1808 the sum granted to the Irish Presbyterian ministers was £45,000. The Regium Donum was withdrawn by the act of 1869 which disestablished the Irish church. Provision was made, however, for existing interests therein, and many Presbyterian ministers continued these on the same terms as the clergy of the church of Ireland.

In England the Regium Donum proper dates from 1721, when Dr. Edmund Calamy (1671-1732) received £500 from the royal bounty "for the use and behalf of the poor widows of dissenting ministers." Afterwards this sum was increased to £1,000, and was made an annual payment "for assisting either ministers or their widows," and later it amounted to £1,695 per annum. It was given to distributors who represented the three denomina-

tions, Presbyterians, Baptists and Independents, enjoying the grant. Among the Nonconformists themselves, however, or at least among the Baptists and the Independents, there was some objection to this form of state aid, and it was withdrawn in 1857.

See J. Stoughton, *History of Religion in England* (1901); J. S. Reed, *History of the Presbyterian Church in Ireland* (Belfast, 1867); and E. Calamy, *Historical Account of my own Life*, edited by J. T. Rutt (1829-30).

REGLA, formerly an important suburb of Havana, Cuba, opposite that city, on the bay; now a part of Havana and an independent municipality. Pop. (1943), 23,037. It was formerly the scene of the Havana bullfights. The church is one of the best in Cuba; the building dates mainly from 1805, but the church settlement goes back to a hermitage established in 1690. Regla is the shipping point of the Havana sugar trade. It has enormous sugar and tobacco warehouses, fine wharves, a dry dock, foundries and an electric railway plant.

Regla is the western terminus of the eastern line of the United Railways of Havana and is connected with the main city of Havana by ferry. A fishing village was established there about 1733. At the end of the 18th century Regla was a principal centre of the smuggling trade, and about 1820 was notorious as a resort of pirates. It first secured an *ayuntamiento* (city council) in 1872; annexation to Havana occurred in 1899.

REGNARD, JEAN FRANÇOIS (1655-1709), French comic dramatist, was born in Paris on Feb. 7, 1655. His masterpieces are *Le Joueur* (Théâtre Français, Dec. 19, 1696), and *Le Légataire universel* (1708). Regnard died on Sept. 4, 1709.

Besides many plays Regnard wrote miscellaneous poems, the autobiographical romance of *La Provençale*, and several short accounts in prose of his travels, published posthumously under the title of *Voyages*.

The first edition of Regnard's works was published in 1731 (5 vols., Rouen and Paris). There is a good selection of almost everything important in the Collection Didot (4 vols., 1819). A selection by L. Moland appeared in 1893. See also a *Bibliographie et iconographie des œuvres de J. F. Regnard* (Paris, Rouquette, 1878); *Le Poète J. F. Regnard en son château de Grillon*, by J. Guyot (Paris, 1907).

REGNAULT, HENRI (1843-1871), French painter, born at Paris on Oct. 31, 1843, was the son of Henri Victor Regnault (q.v.). He studied successively under Montfort, Lamoignon, and Cabanel, and in 1864 exhibited two portraits at the Salon. In 1866, he gained the *Grand Prix* with "Thetis bringing the Arms forged by Vulcan to Achilles" (Beaux-Arts). In Rome Regnault came under the influence of the modern materialistic Hispano-Italian school. His paintings include an imaginative picture of Marshal Prim at the head of his troops, inspired by a glimpse of his subject, received when travelling in Spain; "Judith" (1870), "Salome" and the realistic "Execution without Hearing under the Moorish Kings" painted at Tangiers. Regnault was killed in the Franco-German War on Jan. 19, 1871, while serving under Buzenval.

See *Correspondence de H. Regnault*; Duparc, *H. Regnault, sa vie et son œuvre*; Cazalis, *H. Regnault, 1843-1871*; C. Blanc, *H. Regnault*.

REGNAULT, HENRI VICTOR (1810-1878), French chemist and physicist, was born on July 21, 1810, at Aix-la-Chapelle. His early life was a struggle with poverty, he worked in a drapery establishment in Paris until 1829. Then he entered the École Polytechnique, and passed in 1832 to the École des Mines. A few years later, after studying under Justus von Liebig (q.v.), he was appointed to a professorship of chemistry at Lyons. His most important contribution to organic chemistry was a series of researches, begun in 1835, on the halogen and other derivatives of unsaturated hydrocarbons. He also studied the alkaloids and organic acids, introduced a classification of the metals and effected a comparison of the chemical composition of atmospheric air from all parts of the world. In 1840 he became professor of chemistry in the École Polytechnique, Paris; he was elected a member of the Académie des Sciences, and in 1841 he succeeded Pierre Louis Dulong (q.v.), professor of physics in the Collège de France. In 1847 he published a four-volume treatise on *Chemistry* which has been translated into many languages. Regnault's work in physics was remarkably accurate and painstaking. He designed

apparatus for a large number of measurements which is the standard apparatus of the present.

Regnault executed a careful redetermination of the specific heats of many solids, liquids and gases. (See *CALORIMETRY*.) He investigated the expansion of gases by heat, and showed that, contrary to previous opinion, no two gases had precisely the same coefficient of expansion. By delicate experiments he proved that Boyle's law is only approximately true for real gases. He studied the subject of thermometry (q.v.) critically; he introduced the use of an accurate air-thermometer, and compared its indications with those of a mercurial thermometer, determining the absolute expansion of mercury as a step in the process. He also paid attention to hygrometry and devised Regnault's hygrometer.

In 1854 he was appointed as director of the porcelain manufactory at Sèvres. He carried on his great research on the expansion of gases in the laboratory at Sèvres, but all the results of his latest work were destroyed during the Franco-German War, in which also his son Henri (noticed above) was killed. Regnault never recovered from the double blow, and, although he lived until Jan. 19, 1878, his scientific labours ended in 1872. Regnault's most important work is collected in vols. 21 and 26 of the *Mémoires de l'Académie des Sciences*.

RÉGNIER, HENRI FRANÇOIS JOSEPH DE (1864-1936), French poet and novelist, was born at Honfleur (Calvados) on Dec. 28, 1864, and was educated in Paris for the law. In 1885 he began to contribute to the Parisian reviews, and his verses found their way into most of the French and Belgian periodicals favourable to the symbolist writers. Having begun, however, to write under the leadership of the Parnassians, he retained the classical tradition, though he adopted some of the innovations of Moréas and Gustave Kahn. His gorgeous and vaguely suggestive style shows the influence of Stéphane Mallarmé. His first volume of poems, *Lendemain*, appeared in 1885, and among numerous later volumes are *Poèmes anciens et romanesques* (1890), *Les Jeux rustiques et divins* (1890), *Les Médailles d'argile* (1900), the most famous and the most read of his books of verse, and *La Cité des eaux* (1903). He is also the author of a series of realistic novels and tales, among which are *La Carne de jaspé* (2nd ed., 1897), *La Double Maîtresse* (5th ed., 1900), and *Les Amants singuliers* (1905).

His later works include: *L'Amphibine* (1912); *La Pêcheur* (1920); *Vesigis Flamme* (7th ed., 1921); *Le Divertissement Provincial* (1925); *Proses datées* (1925); *L'Écoute* (1926).

See also E. Gosse, *French Profiles* (1905); van Bever and Leautaud, *Poètes d'aujourd'hui* (1900); H. Berton, *Henri de Régnier, le poète et le romancier* (1910); A. Lowell, *Six French Poets* (1915); and R. Honnert, *Henri de Régnier, son œuvre* (1923).

RÉGNIER, MATHURIN (1573-1613), French satirist, was born at Chartres on Dec. 21, 1573, the son of Jacques Régnier, and Simone Desportes, sister of the poet. Little is known of his youth, except that he received the tonsure at eight years old, and it is chiefly conjecture which fixes the date of his visit to Italy in a humble position in the suite of the cardinal, François de Joyeuse, in 1587. Régnier found his duties irksome, and when, after many years of constant travel in the cardinal's service, he returned definitely to France about 1605, he took advantage of the hospitality of Desportes. In 1606 Desportes died and Régnier obtained a pension of 2,000 livres, chargeable upon one of Desportes' benefices. He was also made in 1609 canon of Chartres through his friendship with the lax bishop, Philippe Hurault, at whose abbey of Royaumont he spent much time in the later years of his dissipated life. The death of Henry IV. deprived him of his last hope of great preferments. He died at Rouen at his hotel, the Écu d'Orléans, on Oct. 22, 1613.

His undoubted work falls into three classes: regular satires in alexandrine couplets, serious poems in various metres, and satirical or jocular epigrams and light pieces, which often, if not always, exhibit considerable licence of language. The real greatness of Régnier consists in the vigour and polish of his satires, contrasted and heightened as that vigour is with the exquisite feeling and melancholy music of some of his minor poems. In these Régnier is a disciple of Ronsard (whom he defended brilliantly

against Malherbe), without the occasional pedantry, the affectation or the undue fluency of the *Péridé*; but in the satires he seems to have had no master except the ancients, for some of them were written before the publication of the satires of Vauguelin de la Fresnaye, and the *Traquies* of D'Aubigné did not appear until 1616. Rénier was an acute critic, and the famous passage (*Satire ix. A Monsieur Rapin*) in which he satirizes Malherbe contains the best denunciation of the merely "correct" theory of poetry that has ever been written. All his merits are displayed in the masterpiece entitled *Macette ou l'Hypocrisie déconcertée*, which does not suffer even on comparison with *Tartuffe*; but hardly any one of the sixteen satires which he has left falls below a very high standard.

Les *Premières Oeuvres* ou *satyres* de Rénier (1608) included the *Discours au roi* and ten satires. There was another in 1609, and others in 1612 and 1613. The author had also contributed to two collections—*Les Muses gaillardes* in 1600 and *Le Temple d'Apollon* in 1611. In 1616 appeared *Les Satyres et autres oeuvres folastres* du sieur Rénier, with many additions and some poems by other hands. Two famous editions by Elsevier (Leiden, 1642 and 1652) are highly prized. The chief editions of the 18th century are that of Claude Brossette (printed by Lyon & Woodman, London, 1729), which supplies the standard commentary on Rénier, and that of Lenglet Dufresnoy (printed by J. Tonnson, London, 1733). The editions of Prosper Poitevin (Paris, 1860), of Ed. de Barthélemy (Paris, 1866), and of E. Courbet (Paris, 1878), may be specially mentioned. The last, printed after the originals in facsimile type, and well edited, is perhaps the best. See also Vianey's *Malherbe Rénier* (1896); M. H. Cherrier, *Bibliographie de Malherbe Rénier* (1884); Jean-Marc Bernard, *L'introduction de la satire en France: Malherbe Rénier* (1913); Emile Roy, *Notes sur les deux poètes Jean et Malherbe Rénier* (1912).

REGNITZ, a river of Germany, 126 m. long, and a left-bank tributary of the Main. It rises in the Jurassic rocks of the Frankish Jura, but its course is along the Trias, through an undulating vine-clad country, past Fürth, Erlangen, Baiersdorf and Forchheim, from which point it is navigable, and joins the Main at Bischofberg, below Bamberg. The Ludwigs canal connects it with the Main and the Danube. Its main tributaries are the Pegnitz, on which is Nürnberg, the Gröndlach and the Wiesent (right), and the Zenn, the Aurach and the Aisch (left). (See MAIN and RHINE.)

REGGRATING, in English criminal law, was the offence of buying and selling again in the same market, or within four miles thereof (O. F. *reggrator*, to sell by retail). (See ENGROSSING.)

REGULA, the Latin word for a rule, hence particularly applied to the rules of a religious order. (See MONASTICISM.) In architecture the term is applied to a rule, a square and the short fillet or rectangular block, under the tænia (q.v.) on the architrave of the Doric entablature. (See ORDER.)

REGULAR (Lat. *regularis*, from *regula*, a rule, O. F. *reule*), orderly, following or arranged according to a rule, steady, uniform, formally correct. Until the sixteenth century the adjective was applied exclusively to the discipline and customs of religious orders bound by a rule, and to their members, who constituted the "regular" as opposed to the "secular" clergy. Thus, as a substantive, "regular" means a monk or friar; while there were bodies of canons regular and canons secular. In more recent military usage, the regular forces was the name for the standing army organized on a permanent system, as opposed to "irregulars," levies raised on a voluntary basis.

REGULATION, AUTOMATIC. Modern processing is required in the production of most of the articles of clothing, food-stuffs, and other items that are used in every day life. Processing requires proper conditions not only in workrooms but in the endless variety of boilers, ovens, furnaces, dryers, sterilizers and other types of apparatus. To insure the proper conditions the automatic regulation of temperature, pressure, humidity, timing, liquid level, flow, specific gravity of the substance being processed and speed of moving parts is of great importance. These eight conditions will be dealt with. Voltage (which must be regulated in many devices), current density (in electroplating, etc.) and other electrical conditions are discussed under INSTRUMENTS, ELECTRICAL, and ELECTRICITY. No discussion is here given of the regulators, controllers or governors incorporated in engines, turbines, gen-

erators and other such machines, since these devices as conceived, designed, built, sold, installed and maintained with the machines, belong to their machines and seldom can function on others.

Automatic regulation of the eight conditions listed above is, however, a science, and the proper application of standardized automatic regulators to improve products and effect economies is a prominent branch of engineering.

Development of Automatic Regulation.—For every industry it has been established that there is one best set of conditions for operation and manufacture. Before the World War, in searching for this "one best way," workers were frequently required to watch indicators and manipulate valves and levers constantly in order to maintain proper conditions, until a fairly suitable automatic device was purchased or painstakingly constructed. Today (1929) specialists may install the required automatic devices as soon as the particular requirements are known. One of the factors that have made this possible is the spread of knowledge of formerly secret processes. This has led to "professional divisions" within the larger engineering societies and to co-operative industrial "institutes" and research bureaux. Competition between industries has also led to the exchange of formulae and data on automatic processes. Instrument-makers have pursued an increasingly active policy of scientific research into processes, with two objectives: (1) the development and standardization of classes and types of automatic regulators, based on industrial requirements; (2) the improvement and standardization of processes through methods worked out by their research staffs.

All these tendencies point to the need of an agency for the systematic utilization of scientific achievements. A central "institute" under the auspices of instrument makers may ultimately be developed. The progress of the last decade will undoubtedly be eclipsed when manufacturers thus combine their research and present their united facilities to the instrument-using industries. For example, the standardization of bulbs, connections, protective sockets, thermocouples, charts, scales, ranges, etc., has been initiated in the United States, but as yet only on a small scale.

Types of Automatic Regulators.—All regulators require some form of power to operate a valve, damper, etc., in order to maintain the optimum condition.

Self-operating regulators requiring no auxiliary power are directly installed (i.e., on a steam line) and usually consist of a globe or balanced valve operated by a bellows; the expansion of the bellows being obtained in temperature regulators by the dilation or evaporation of a liquid in a sensitive bulb, and in pressure regulators by the pressure which is to be regulated. This group of devices includes thermostats and damper regulators.

Air-operated regulators are the most wide-spread in industrial process service. They utilize the ample and flexible power of compressed air, controlling its flow to an operative mechanism which usually embodies an elastic diaphragm. Pilot valves add extreme sensitiveness to ample power, obviating the use of bellows—a small capillary or spiral spring or Bourdon tube being sufficient. (See Plate, figs. 6 and 7.)

Electrically operated regulators function on the relay principle and actuate standardized electrical mechanisms. Heavy work may be performed through their agency but their on-and-off action produces the frequently objectionable "saw-tooth" record. On a temperature application, for instance, the steam valve would "hunt" whereas air-operated regulators can provide exact throttling regulation. (See Plate, fig. 1.)

Steam-operated regulators utilize the power of the steam which they control. They embody the sensitive bulb, capillary tube and capillary spring. This latter operates a pilot valve so located that the pressure above a steam diaphragm may be varied with respect to the pressure below it. Pressure fluctuations of the steam supply cannot destroy accuracy, for the differential principle is used. Valves up to 4 in. are successfully operated by diaphragms up to 11 in. diameter. (See Plate, figs. 3 and 4.)

Temperature Systems. Fixed Stem.—It is sometimes possible to use the "solid expansion" principle, and the sensitive member then consists of a bimetallic stem (or of a carbon or quartz rod

BY COURTESY OF (1, 2, 4) THE C. J. TAGLIAPIETRA MANUFACTURING COMPANY, (3) THE SHOWN INSTRUMENT COMPANY, (5) THE REPUBLIC FLOW METERS COMPANY, (6, 7) THE FOXBORO COMPANY

INSTALLATIONS OF AUTOMATIC CONTROLLERS IN VARIOUS INDUSTRIES

1. Process controller in milk pasteurization. The automatic cycle controller, on the pedestal to left, regulates the filling of each of the separate pasteurization vats, to the right, with the proper quantity of milk; holds the fluid for the required length of time; maintains the proper heat at a uniform temperature, and empties the vats when the cycle has been completed. 2. Process controller in tyre manufacturing. Automatic combination controllers which maintain the correct cure temperature and the time in tyre vulcanization. 3. Regulating and indicating instruments in a modern boiler room, indicating and regulating the flow of steam, air, water and gas. 4. Steam-operated temperature controllers on a bottle washing

machine. 5. Decorating lehr, or heated oven, in a glass plant. High grade perfumery bottles are passed through the lehr for annealing and burning on the enamel decorations. An automatic control pyrometer governs the motor-driven valve in the rectangular box to the right. 6. Interior of a temperature recorder-controller. Air-operated recorder showing heliost tubes which actuate a flapper valve, one for heat control and the other for vapour or humidity control. All temperature variations are recorded graphically. 7. Diaphragm temperature control valve, air-operated. Among other uses the valve may be installed in an oil still, dyeing machine, tyre press, or pasteurization vat.

within a metal tube) to which the instrument "head" with its graduated dial is directly attached. The great majority of applications, however, demand a *remote* bulb or thermocouple with either a closed system or an electrical system.

Closed Systems consist of bulb, capillary tube and Bourdon tube or capillary spring. They are either *completely* filled with mercury, another liquid or a gas; or *partially* filled with a volatile liquid the vapour pressure of which is utilized.

Electric Systems possess three advantages: (1) applicability to high temperature work, (2) practicality of long distance regulation, (3) replaceability of sensitive element. **Radiation Pyrometric Systems** are seldom used for automatic regulation. **Resistance Systems** are applicable for temperatures up to 300° F with base metal (nickel) elements and up to 1,500° F with platinum. **Thermoelectric Systems** may be of the galvanometric or potentiometric type. The latter has several advantages for "medium" temperatures. Usual range limitations are 300° to 1,800° F with base metal and 1,000° to 2,500° F with rare metal couples.

Other Conditions. Pressure.—The majority of pressure regulators are of the self-operating type, but for process work the air-operated type is being increasingly adopted. "Absolute pressure" and "differential pressure" regulators are in use in gas and by-product plants.

Humidity.—In general, instruments regulating the humidity in dryers consist of a pair of automatic temperature regulators of the closed system type—the bulb of one being affected by "air temperature" while the bulb of the other is enclosed in a constantly moistened porous sleeve exposed to the cooling effect of fairly rapid air circulation. The dry-bulb regulator unit controls the source of heat, while the wet-bulb unit controls the "spray." Many ingenious humidity regulators have recently appeared, including models which provide a "drying schedule."

Timing.—The first automatic regulators for this purpose were "modified alarm clocks." Modern ones dependably perform the complex cycles of operations required in vulcanization, dyeing, pasteurization of milk, etc. (See *Roson*.)

Liquid Level.—An "automatic liquid level regulator" is to be found in every modern bathroom, but the industrial types necessarily differ. They utilize auxiliary power to operate large valves. Extra heavy and corrosion-resisting models are used in petroleum refineries and chemical plants under severe temperature and pressure conditions.

Flow.—While flow meters are being increasingly adopted in power plants and numerous industries, the demand for automatic regulation of flow has not as yet brought about the full development of special instruments.

Specific Gravity.—Two types of devices which automatically regulate the density of the substance being processed are commercially manufactured. One utilizes the hydrometric principle and embodies a float chamber; the other utilizes the electrical resistance of the substance being processed.

Speed.—Standardized commercial devices consist essentially of tachometers provided with electric contacts or other means of operating levers, rheostats or other appliances.

See *The Instrument World* (London) and *Instruments* (Pittsburgh, Pa.). (M. F. Bk.)

REGULUS, MARCUS ATILIUS, Roman general and consul (for the second time) in the ninth year of the First Punic War (256 B.C.). He was one of the commanders in the naval expedition which shattered the Carthaginian fleet at Ecnomus, and landed an army on Carthaginian territory (see *PUNIC WARS*).

The other consul was recalled, Regulus being left behind to finish the war. After a severe defeat at Adys near Carthage, the Carthaginians were inclined for peace, but the terms proposed by Regulus were so harsh that they resolved to continue the war. In 255, Regulus was completely defeated and taken prisoner by the Spartan Xanthippus. There is no further trustworthy information about him. According to tradition, he remained in captivity until 250, when after the defeat of the Carthaginians at Panormus he was sent to Rome on parole to negotiate a peace or exchange of prisoners. On his arrival he strongly urged the senate to refuse both proposals, and returning to Carthage was

tortured to death (Horace, *Odes*, iii. 5). The story is insufficiently attested; it may have been invented to excuse the treatment of Carthaginian prisoners at Rome but it served to make Regulus the type of heroic endurance to the later Romans.

REHAN, ADA (1860-1916), American actress, whose real name was Crehan, was born in Limerick, Ireland, on April 22, 1860. Her parents removed to the United States when she was five years old. She made her first stage appearance in *A Cross the Continent* at Newark (N.J.), in 1874. She was with Mrs. John Drew's stock company in Philadelphia, John W. Albright's in Albany and Baltimore, and other companies for several seasons, playing a variety of minor parts, until she became connected with Augustin Daly's theatrical management in 1879. Under his training she soon showed her talents for vivid, charming portrayal of character in modern and older comedies.

She was the heroine in all the Daly adaptations from the German, and added to her triumphs the parts of Peggy in Wycherly's *Country Girl*, Julia in the *Hunchback*, and especially Katharina in *The Taming of the Shrew*, besides playing Rosalind and Viola. Miss Rehan accompanied Daly's company to England (first in 1884), France and Germany (1886). She died in New York city, on Jan. 8, 1916.

REHOBOAM, son and successor of king Solomon (*q.v.*), began to reign c. 937 B.C. He was not acceptable to the northern tribes of Israel, who recalled Jeroboam from his exile in Egypt and made Rehoboam's contemptuous refusal of their demands the occasion for instituting a rival kingdom under Jeroboam (I Kings xii.). It is probable that this was done with the encouragement of Egypt. Shishak of Egypt attacked the kingdom of Judah c. 930, and despoiled the temple at Jerusalem of its treasures. Rehoboam's reign was marked by constant conflict with the kingdom of Israel. An unfavourable judgment is pronounced on him by the editor of Kings because he favoured customs connected with Baal worship. The fact that his mother was an Ammonitess may in some measure account for this. He was succeeded after a reign of 17 years by his son Abijah (in I Kings, Abijam) of whom little is known save a victory over Jeroboam.

REICHENAU, a picturesque island in the Untersee or western arm of the lake of Constance, 3 mi. long by 1 broad, and connected with the east shore by a causeway (three-quarters of a mile long). It is in the *Land* of Baden, Germany. It had 2,606 inhabitants in 1933. The soil is fertile, and excellent wine is produced in sufficient quantity for exportation. The Benedictine abbey of Reichenau, founded in 724, was long celebrated for its wealth and for the services rendered by its monks to the cause of learning. In 1540 the abbey, which had previously been independent, was annexed to the see of Constance, and in 1799 it was secularized. The abbey church, dating in part from the 9th century, contains the tomb of Charles the Fat (d. 888), who retired to this island in 887, after losing the empire of Charlemagne.

REICHENBACH, a town in the Prussian province of Silesia, Germany, on the Peile, at the foot of the Eulengebirge, a spur of the Riesengebirge, 30 mi. S.W. of Breslau by rail. Pop. (1939) 17,045. Among its industries are dyeing, brewing and machine building and the manufacture of chemicals and glass buttons, and there is a considerable trade in grain and cattle. Here was held, in 1790, the congress which resulted in the convention of Reichenbach—between Great Britain, Prussia, Austria, Poland and Holland—guaranteeing the integrity of Turkey. Here, too, in 1813, was signed the treaty for the prosecution of the war against France.

REICHENBACH, a German town in Saxony, situated in the Vogtland, 11 mi. S.W. of Zwickau, at the junction of the main lines of railway Dresden-Leipzig-Hof. Pop. (1939) 31,266. The earliest mention of the town occurs in a document of 1212. The woollen manufacture was introduced in the 15th century, and took the place of the mining industry. The industries include the manufacture of textile goods and machinery and dyeing.

REICHENBERG: see *LIBEREC*.

REICHENHALL, German town in Upper Bavaria, on the river Saalach, 1,570 ft. above sea level, 9 mi. S.W. of Salzburg. Pop. (1939) 13,156. The brine springs of Reichenhall are mentioned in a document of the 8th century and were perhaps known to the Romans; but almost all trace of antiquity of the town was destroyed by a conflagration in 1834. The brine conduit to Traunstein dates from 1618. The water of some of the springs, the sources of which are 50 ft. below the surface, is so strongly saturated with salt (up to 24%) that it is at once conducted to the boiling houses, while that of the others is first submitted to a process of evaporation. Reichenhall is the centre of the four chief Bavarian saltworks: Berchtesgaden, Traunstein and Rosenheim. In the 19th century it became an important health resort.

REICHSBANK. The Reichsbank was the central note-issuing bank of Germany until 1945. It was founded in 1875 to provide the newly created German reich (empire) with a uniform monetary system. Although its shares were privately held, it operated under government control. The Reichsbank was primarily a bankers' bank, though it granted credit to private business firms as well as banks. Moreover, it performed the functions of a bankers' clearing house through a "giro" system under which bankers and other clients maintaining balances at the Reichsbank could make payments to one another without charge, by means of entries in the books of the Reichsbank. These "giro" transfers served to some extent in place of cheques, which were hardly known in Germany in the 19th century. Later, as the use of cheques developed, the Reichsbank set up a cheque clearing office in addition to its "giro" system. Of the numerous state and private note-issuing banks existing before the establishment of the Reichsbank, only four survived in 1914. Their note circulation was insignificant compared with that of the Reichsbank, and they were liquidated in 1935. Under its original statutes of 1875, the amount of notes which the Reichsbank could issue in excess of its gold reserve was subject to a maximum limit. Moreover, to safeguard the convertibility of its notes, the bank was obliged to maintain its gold reserve at a level equal to at least one-third of the notes outstanding. For the remaining two-thirds, only commercial bills were eligible as cover.

These provisions were suspended at the outbreak of World War I in 1914. To help the government in financing the war, the Reichsbank had to take up ever-increasing amounts of treasury bills and bonds. As a result, the note circulation was greatly expanded. But it was after the war that the flood of paper money became truly disastrous. The government continued to rely heavily on the Reichsbank in order to meet its expenditure. The inflationary pressure rose to a peak early in 1923 when the government undertook to finance the passive resistance of the local population during the French occupation of the Ruhr. This gave the mark its death-blow. The extent of the inflation is illustrated by the ratio at which the new reichsmark currency was introduced in 1924; namely, 1 new reichsmark = 1,000,000,000,000 old marks. (See GERMANY; MARK.)

In the autumn of 1923, government borrowing from the Reichsbank was severely curtailed; the depreciation of the old mark was in consequence arrested; and a strictly limited amount of "rentenmark" notes was put into circulation to serve as a stable medium of exchange in the transition period pending the issue of new reichsmark notes by a thoroughly reformed Reichsbank.

Reconstitution of 1924.—A new bank law embodying the Reichsbank's revised statutes was passed on Aug. 30, 1924, giving effect to the Dawes plan which had been adopted at the London conference in an endeavour to settle the German reparation problem. The Reichsbank was to play some part in the procedure established for the collection and transfer of reparations. To ensure a certain degree of foreign control, a council composed of 7 German and 7 foreign representatives was set up, with the power to appoint the bank's president and directors. Under the Young plan in 1930, the foreign representatives were withdrawn. (See REPARATIONS.)

In the law of 1924 it was expressly stated that the Reichsbank was independent of the government. The provisions regarding the note issue were altered. A maximum limit such as existed before

1914 was not reimposed; but the minimum cover ratio was raised from the prewar 33% to 40%. Three-fourths of the cover reserve had to be in gold; one-fourth could be held in foreign exchange. If the reserve fell below 40%, the bank had to pay a tax and raise its discount rate according to a predetermined schedule. As before 1914, only commercial bills were admitted as cover over and above the legal minimum reserve.

The reconstituted Reichsbank obtained its initial gold and exchange reserves largely through an international loan floated under the Dawes plan. The bank was obliged by law to redeem its notes in gold at a fixed rate so as to maintain the gold parity re-established in 1924. This obligation was to come into effect by a special resolution, which was not passed until 1930. In practice, however, the Reichsbank bought and sold foreign exchange without limitation, at rates consistent with the legal gold value of the reichsmark.

The international financial crisis which started with the collapse of a leading Austrian bank in May 1931 led to a sudden withdrawal of foreign short-term credits, as a result of which the Reichsbank lost the greater part of its gold and foreign exchange. In July 1931 the reserve ratio fell below 40%, and the bank sharply increased its discount rate. As the outflow of gold continued unchecked, resort was had to restrictions which put an end to the free convertibility of Reichsbank notes into gold or foreign currencies. Exchange control was intended as an emergency measure; but it came to stay, and was indeed rendered increasingly severe as time went on. Especially in the early stages, the Reichsbank played an important part in the administration of exchange control. The various emergency decrees issued in the summer of 1931 gave it a virtual monopoly of foreign exchange transactions. Some of its exchange-control functions were, however, later transferred to the ministry of national economy.

In the domestic field also, the Reichsbank had to face grave difficulties during the depression. Several big commercial banks became insolvent or illiquid, and the Reichsbank, through its subsidiary, the Gold Discount bank, furnished some of them with fresh resources, taking over a part of their share capital.

The Reichsbank under Hitler.—Under the national socialist regime, the Reichsbank lost the autonomous status it had received in 1924. State control became absolute, even though the shares of the bank remained mostly in private ownership. There was a decline in the authority of the Reichsbank, reflecting the diminished importance of monetary instruments of policy under a government which did not hesitate to employ the more forcible methods of direct regimentation in economic affairs. Before as well as after the outbreak of war in 1939, the Reichsbank became more and more a passive agency for issuing new money against treasury bills or bonds in any form or quantity determined by the government.

This general trend began to show itself in Oct. 1933, when the bank law was amended in three ways. First, the council mentioned earlier was abolished, and the chancellor, Hitler, himself was thenceforth to appoint and dismiss the president and directors of the bank. Secondly, the provisions concerning the tax and the discount rate whenever the reserve ratio was below 40% were abrogated, and the 40% reserve requirement became a dead letter. Thirdly, the Reichsbank was authorized to purchase government bonds and to count them as cover to the note issue.

In addition to the Gold Discount bank, founded in 1924, two further subsidiaries were attached to the Reichsbank in 1933-34, one to receive the blocked reichsmark payments by which German debtors nominally discharged their foreign liabilities and the other to handle the bilateral clearing arrangements which Germany concluded with some 40 countries.

In 1937 Hitler proclaimed the "unlimited sovereignty of the reich" over the Reichsbank. Finally, by a law of June 15, 1939, the bank received a new formal constitution, the third in its history. This law stated that the Reichsbank shall be "responsible directly to the fuhrer and chancellor" (Section 1); that the maximum amount of treasury bills which the bank may hold shall be determined by the chancellor; and that the bank's note circulation shall be covered primarily by commercial bills, treas-

ury bills, securities and loans against securities. Gold and foreign exchange were admitted only as "additional" note cover, to be kept "at such a level as is deemed necessary in order to settle balances with foreign countries and maintain the value of the currency" (Section 27).

The Reichsbank took over the Austrian National bank and the Bank of Danzig when Austria and Danzig were incorporated into the reich in 1938 and 1939, and established branches in other territories thus incorporated.

In areas occupied but not formally annexed by Germany during and after 1939, the Reichsbank had little or no direct concern, though many of its officials were sent there to supervise the currency arrangements. The German authorities in the occupied areas made use of the existing local currencies or issued special occupation money.

The Reichsbank after World War II.—The head office of the bank in Berlin was closed in 1945 and its branches in eastern Germany liquidated.

In western Germany, as part of the Allied decentralization of the German banking system, the bank was put into liquidation, 1947-48, and its functions transferred to land central banks and the Bank Deutscher Länder. (R. Ne.; X.)

REICHSTADT, NAPOLEON FRANCIS JOSEPH CHARLES, Duke of (1811-1832), known by the Bonapartists as Napoleon II, was the son of the Emperor Napoleon I and Marie Louise, archduchess of Austria. He was born on March 20, 1811, in Paris at the Tuileries palace. He was at first named the king of Rome, after the analogy of the heirs of the emperors of the Holy Roman Empire. By his birth the Napoleonic dynasty seemed to be finally established; but in three years it crumbled in the dust.

At the time of the downfall of the empire (April 1814) Marie Louise and the king of Rome were at Blois with Joseph and Jerome Bonaparte, who wished to keep them as hostages. This design, however, was frustrated. Napoleon abdicated in favour of his son; but events prevented the reign of Napoleon II from being more than titular.

While Napoleon repaired to Elbe, his consort and child went to Vienna; and they remained in Austria during the Hundred Days (1815), despite efforts made by the Bonapartists to carry off the prince to his father at Paris.

In the settlements of 1814 and 1815 (see MARIE LOUISE)—the powers opposed all participation of the prince in the affairs of his mother's duchy of Parma. He therefore remained at Vienna.

From this time onward he became, as it were, a pawn in the complex game of European politics, his claims being put forward sometimes by Metternich, sometimes by the unionists of Italy, while occasionally malcontents in France used his name to discredit the French Bourbons. In November 1816 the court of Vienna informed Marie Louise that her son could not succeed to the duchies. This decision was confirmed by the treaty of Paris of June 10, 1817. The title of "duke of Reichstadt" was conferred on him on July 22, 1818 by way of compensation. Thus Napoleon I, who once averred that he would prefer that his son should be strangled rather than brought up as an Austrian prince, lived to see his son reduced to a rank inferior to that of the Austrian archdukes.

His education was confided chiefly to Count Dietrichstein, who found him precocious, volatile, passionate and fond of military affairs. His nature was sensitive, as appeared on his receiving the news of the death of his father in 1821. The upheaval in France in 1830 and the disturbances which ensued led many Frenchmen to turn their thoughts to Napoleon II; but though Metternich dallied for a time with the French Bonapartists, he had no intention of inaugurating a Napoleonic revival.

The duke's indulgence in physical exercise far beyond his powers aggravated a natural weakness of the chest, and he died on July 22, 1832.

REID, SIR GEORGE (1841-1913), knighted in 1902, Scottish artist, was born in Aberdeen on Oct. 31, 1841. He was apprenticed in 1854 for seven years to Messrs. Keith & Gibb, lithographers in Aberdeen. In 1861 Reid took lessons from an itinerant portrait-painter, William Niddie, who had been a pupil of James Gills, R.S.A., and afterwards entered the school of the Board of Trustees in Edinburgh. His first portrait of interest was that of George Macdonald, the poet and novelist, now the property of the university of Aberdeen. In 1865 he went to Utrecht to study under A. Mollinger, whose work he admired for its unity and simplicity. For some years after this his work failed to please the Scottish authorities, but after his further studies under Yvon in Paris and Josef Israëls at The Hague, Reid's success was assured. A typical landscape is his "Whins in Bloom," which combines great breadth with fine detail. His flower-pieces, such as "Roses," were brilliant, but his most individual work is found in his portraits, which show great insight.

REID, SIR GEORGE HOUSTON, K.C.M.G., 1909 (1845-1918), Australian politician, was born on Feb. 25, 1845, at Johnstone, Renfrewshire, and emigrated in 1852 to Australia. He practised as a barrister in Sydney and was elected to the New South Wales parliament in 1880. In 1883-84 he was minister of public instruction and from 1891-94 was leader of the free trade party. In 1894 he became premier and retained office until 1899. Reid played a conspicuous part in the federation movement and was a member of the first Commonwealth parliament in 1901, leading the free trade opposition to Sir Edmund Barton. In 1904 he became Prime Minister, but he stood for a programme which was unacceptable to a predominantly protectionist country, and after his fall in the following year he never again held office. He led the opposition from 1905-08 and in the latter year retired from Australian politics. In 1909 he was appointed high commissioner in London; and on the expiration of his term entered the House of Commons as Conservative member for St. George's, Hanover Square, London. He published *My Reminiscences* in 1917. He died on Sept. 12, 1918.

REID, ROBERT (1862-1929), American artist, was born at Stockbridge (Mass.), on July 29, 1862. He studied at the art schools of the Boston Museum of Fine Arts, the Art Students' League, New York, and under Boulanger and Lefebvre in Paris. His early pictures were figures of French peasants, painted at Étampes, but subsequently he became best known for mural decoration and designs for stained glass. He contributed with others to the frescoes of the dome of the Liberal Arts Building at the Columbian Exposition, Chicago, in 1893. Other work is in the Congressional Library, Washington, the Appellate Court House, New York, and the State House, Boston, where are his three large panels, "James Otis Delivering his Speech against the Writs of Assistance," "Paul Revere's Ride," and the "Boston Tea Party." He executed a panel for the American pavilion at the Paris Exhibition, 1900, and in 1906 he completed a series of ten stained glass windows for a church at Fairhaven (Mass.), for the Rogers memorial. In 1906 he became a full member of the National Academy of Design. He died at Clifton Springs, New York, on December 2, 1929.

REID, SIR ROBERT GILLESPIE (1840-1908), Canadian railway contractor, was born at Coupar-Angus, Scotland. When a young man he spent a few years in Australia gold-mining, and in 1871 he settled in America, where he began his career as a contractor. He built one section of the Canadian Pacific railway, and was responsible for the erection of the international bridge over the Niagara river, the international railway bridge over the Rio Grande river and the Lachine bridge over the St. Lawrence. In 1893 Reid signed a contract with the government of Newfoundland by which he undertook to construct a railway from St. John's to Port-aux-Basques and to work the line for ten years in return for a large grant of land. In 1898 he further contracted to work all the railways in Newfoundland for 50 years on condi-

tion that at the end of this time they should become his property. This bargain, which included other matters such as steamers, docks and telegraphs, was extraordinarily favourable to Reid, who, by further enormous grants of land, became one of the largest landed proprietors in the world; public opinion was aroused against it, and eventually the terms of the contract were revised, being made more favourable to Newfoundland, and Reid's interests were transferred to a company, the Reid Newfoundland Company, of which he was the first president (see *NEWFOUNDLAND: History*). Reid was knighted in 1907. He died on June 3, 1908.

REID, THOMAS (1710-1796), the founder of the "Scottish School" of philosophy, was born on April 26, 1710, at Strachan in Kincardineshire, where his father was minister. He graduated at Aberdeen in 1726, remained there as librarian for ten years, and was presented to the living of Newmachar near Aberdeen in 1737. His first philosophical work, *Essay on Quantity*, occasioned by reading a *Treatise in which Simple and Compound Ratios are applied to Virtue and Merit*, denying the possibility of mathematical treatment of moral subjects, appeared in the *Transactions of the Royal Society* (1748). In 1740 Reid married a cousin, the daughter of a London physician. In 1752 he became professor of philosophy at King's college, Aberdeen. The Aberdeen Philosophical Society (the "Wise Club"), which numbered among its members Campbell, Beattie, Gerard and Dr. John Gregory, was mainly founded by Reid, who was secretary for the first year (1758). Reid propounded his point of view in the *Enquiry into the Human Mind on the Principles of Common Sense* (1764). In this year, Reid succeeded Adam Smith as professor of moral philosophy at Glasgow.

After 17 years he retired to complete his philosophical system. The *Essays on the Intellectual Powers of Man* appeared in 1785, and their ethical complement, the *Essays on the Active Powers of the Human Mind*, in 1788. These, with an account of Aristotle's *Logic* appended to Lord Kames's *Sketches of the History of Man* (1774), conclude the list of works published in Reid's lifetime. He died of paralysis on Oct. 7, 1796.

The key to Reid's philosophy is to be found in his revision from the sceptical conclusions of Hume. In several passages of his writings he expressly dates his philosophical awakening from the appearance of the *Treatise of Human Nature*. In the dedication of the *Enquiry*, he says: "The ingenious author of that treatise upon the principles of Locke—who was no sceptic—hath built a system of scepticism which leaves no ground to believe any one thing rather than its contrary. His reasoning appeared to me to be just; there was, therefore, a necessity to call in question the principles upon which it was founded, or to admit the conclusion." Having decided that the rationalist philosophy was subversive of religion and morals he examined the doctrine, which he declared to be contrary to experience. He appealed not to eternal truths, but to the testimony of experience. He maintained that we do not start with "ideas," and afterwards refer them to objects; we are never restricted to our own minds, but are from the first immediately related to a permanent world. There are certain presuppositions unassailable by doubt which are older and more authoritative than any philosophy. Among these he places the belief in a material external world and in the existence of the soul. Reid has a variety of names for the principles which, by their presence, lift us out of subjectivity into perception. One of these, "principles of common sense," which became the current one, conveyed a false impression of Scottish philosophy. Reid did not merely appeal from the reasoned conclusions of philosophers to the unreasoned beliefs of common life. His real mode of procedure is to reargue Hume's conclusions by a refutation of the premises inherited by him from his predecessors. Reid everywhere unites common sense and reason, making the former "only another name for one branch or degree of reason." Reason, as judging of things self-evident, is called common sense to distinguish it from ratiocination or reasoning. And in regard to Reid's favourite proof of the principles in question by reference to "the consent of ages and nations, of the learned and unlearned," it is only fair to observe that this argument assumes a much more

scientific form in the *Essays*, where it is almost identified with an appeal to "the structure and grammar of all languages." "The structure of all languages," he says, "is grounded upon common sense." To take but one example, "the distinction between sensible qualities and the substance to which they belong, and between thought and the mind that thinks, is not the invention of philosophers; it is found in the structure of all languages, and therefore must be common to all men who speak with understanding" (Hamilton's *Reid*, pp. 229 and 454).

BIBLIOGRAPHY.—The best edition of Reid's *Works* is that by Sir William Hamilton (2 vols.). See also "Reid and the Philosophy of Common Sense" in J. F. Ferrier's *Lectures*, ed. Grant and Lushington (1866); A. C. Fraser, *Thomas Reid* ("Famous Scots Series," 1883); K. Peters, *Thomas Reid als Kritiker von David Hume* (Leipzig, 1909); O. M. Jones, *Empiricism and Intuitionism in Reid's Common Sense Philosophy* (1927).

REID, THOMAS MAYNE (1818-1883), better known as MAYNE REID, British novelist, the son of a Presbyterian minister, was born at Ballyronney, Co. Down, Ireland, on April 4, 1818. His own early life was as adventurous as any boy reader of his novels could desire. When 20 years old he went to America in search of adventure. He traded on the Red river, studying the ways of the red man and the white pioneer; he made acquaintance with the Missouri in the same way. In Philadelphia, where he was engaged in journalism from 1843 to 1846, he made the acquaintance of Edgar Allan Poe. When the war with Mexico broke out in 1846 he obtained a captain's commission, was present at the siege and capture of Vera Cruz, and led a forlorn hope at Chapultepec, where he sustained such severe injuries that his life was despaired of. In one of his novels he says that he believed theoretically in the military value of untrained troops, and that he had found his theories confirmed in actual warfare. He offered his services to the Hungarian insurgents in 1849, raised a body of volunteers, and sailed for Europe, but arrived too late. He then settled in England, and began his career of a novelist with the publication, in 1850, of the *Rifle Rangers*. This was followed next year by the *Scalp Hunters*. He never surpassed his first productions, except perhaps in *The White Chief* (1859) and *The Quadroon* (1859); but he continued to produce tales of self-reliant enterprise and exciting adventure with great fertility. He died in London on Oct. 22, 1883.

See *Memoir* (1890) by his widow, Elizabeth Mayne Reid.

REID, WHITELEW (1837-1912), American journalist and diplomatist, was born of Scotch parentage, near Xenia, O., on Oct. 27, 1837. He graduated at Miami University in 1856, and spoke frequently in behalf of John C. Frémont, the Republican candidate for the presidency in that year. In 1860 he became legislative correspondent at Columbus for several Ohio newspapers, including the *Cincinnati Gazette*, of which he was made city editor in 1861. He was war correspondent for the *Gazette* in 1861-62, serving also as volunteer aide-de-camp to generals Thomas A. Morris, William S. Rosecrans in West Virginia, and was Washington correspondent of the *Gazette* in 1864-68. In 1868 he became a leading editorial writer for the *New York Tribune*, in the following year he was made managing editor, and in 1872, upon the death of Horace Greeley, became the principal proprietor and editor-in-chief. In 1905 Reid relinquished his active editorship of the *Tribune*, but retained financial control. He served as minister to France in 1889-92, and in 1892 was the unsuccessful Republican candidate for vice president on the ticket with Benjamin Harrison. In 1897 he was special ambassador of the United States on the occasion of Queen Victoria's jubilee; in 1902 was special ambassador of the United States at the coronation of King Edward VII, and in 1905 became ambassador to Great Britain. In 1881 he married a daughter of Darius Ogden Mills (1825-1910), a prominent financier. He died in London on Dec. 15, 1912.

His publications include *After the War* (1867); *Ohio in the War* (1868); *Some Consequences of the Last Treaty of Paris* (1899); *Our New Duties* (1899); *Later Aspects of Our New Duties* (1899); *Problems of Expansion* (1900); *The Greatest Fact in Modern History* (1906); *How America Faced its Educational Problem* (1906); *The Scot in America and the Ulster Scot* (1912), and posthumously, *American and English Studies* (1913).

See Royal Cortissoz, *The Life of Whiteleaf Reid* (1921).

REIDSVILLE, a town of Rockingham county, North Carolina, U.S.A., in the northern part of the state, at an altitude of 822 ft.; on the Southern railway and federal highway 29 and state highways 158, 67 and 68; 24 mi. S.W. of Danville, Va. Pop. 11,760 in 1950. It is a tobacco marketing and shipping point; has cotton and silk mills, cotton bags, leather preservative and woodworking plants. One plant makes 100,000,000 cigarettes daily. The city was founded about 1829 and incorporated in 1873. It has a commission-manager form of government.

REIGATE, a market town and municipal borough in the Reigate parliamentary division of Surrey, England, 24 mi. S.W. of London by the S.R. Pop. (est. 1938) 36,630. Area, 16 sq. mi. Reigate (Cherchefelle, Regat, Reygate), at a cross-road on the Pilgrim's Way, at the foot of the North Downs, had a castle, a stronghold of the Warennes in the 12th, 13th and 14th centuries. On the death of Edith, the widow of Edward the Confessor, to whom it belonged, William I secured the manor of Cherchefelle. It was granted by William Rufus to Earl Warenne, through whose family it passed in 1347 to the earls of Arundel. The name Reigate occurs in 1299. Burgesses of Reigate are mentioned in a close roll of 1348, but no early charter is known. The town was incorporated in 1863. It returned two members to parliament from 1295 till 1831, and afterwards one member until 1867, when it was disfranchised for corruption. Of the old castle (destroyed c. 1648), there remains only the entrance to a cave beneath, 150 ft. long and from 10 to 12 ft. high, excavated in the sandstone, which was used as a guardroom. The grounds are laid out as a public garden. The old town hall (1708) is on the site of an ancient chapel dedicated to St. Thomas Becket. In the chancel of the parish church of St. Mary (Transitional Norman to Perpendicular) is buried Lord Howard, the commander of the English navy against the Spanish Armada. The grammar school was founded in 1675. The borough, which was considerably extended in 1933, contains the modern town of Redhill.

REIMARUS, HERMANN SAMUEL (1694-1768), German philosopher and man of letters, was born at Hamburg, on Dec. 22, 1694. He was educated by his father and by the famous scholar J. A. Fabricius, whose son-in-law he became, and later at Jena. He was professor of Hebrew and Oriental languages in the high school of his native city from 1727 till his death. His house was the centre of the highest culture, and a monument of his influence in that city still remains in the *Haus der patriotischen Gesellschaft*, where the learned and artistic societies partly founded by him still meet. He died on March 1, 1768.

Reimar's reputation as a scholar rests on the valuable edition of Dio Cassius (1750-52) which he prepared from the materials collected by J. A. Fabricius. He also published *Abhandlungen von den vornehmsten Wahrheiten der natürlichen Religion* (Hamburg, 1754, 6th ed. 1791); *Vernunftlehre* (Hamburg and Kiel, 1756, 5th ed., 1790); *Betrachtungen über den Kunsttrieb der Thiere* (Hamburg, 1762, 4th ed., 1798). But his best-known work is his *Apologie oder Schutzschrift für die vernünftigen Verehrer Gottes* (kept back during his lifetime) from which, after his death, Lessing published certain chapters under the title *Wolfenbüttel Fragments* (see LESSING, GOTTFRIED EPHRAIM). Other portions were published by "C. A. Schmidt" (1787) and D. W. Klose (1850-52). The original MS. is in the Hamburg town library.

The standpoint of the *Apologie* is that of pure naturalistic deism. Miracles and mysteries, with the exception of the Creation, are denied, and natural religion is put forward as the absolute contradiction of revealed. The essential truths of the former are the existence of a wise and good Creator and the immortality of the soul. These truths are discoverable by reason, and are such as can constitute the basis of a universal religion and lead to happiness. A revealed religion could never obtain universality, as it could never be intelligible and credible to all men.

See the "Fragments" as published by Lessing, reprinted in vol. xv. of *Lessing's Werke*, Hempel's edition; D. F. Strauss, *H. S. Reimar und seine Schutzschrift für die vernünftigen Verehrer Gottes* (1862, 2nd ed., 1877); C. Voysey, *Fragments from Reimar's* (1879) (a translation of Strauss's book, with the second part of the seventh fragment, on the "Object of Jesus and his Disciples"); R. Schettler,

Die Stellung d. Philos. Reimar's zur Religion (Leipzig, 1904), and J. Engert, *Reimar als Metaphysiker* (Paderborn, 1909).

REIMS (RHEIMS), a city of north-eastern France, chief town of an arrondissement of the department of Marne, 98 mi. E.N.E. of Paris, on the Eastern railway. Pop. (1946) 110,749. Reims stands in a plain on the right bank of the Vesle, a tributary of the Aisne, and on the canal which connects the Aisne with the Marne. South and west rise the "montagne de Reims" and vine-clad hills.

Before the Roman conquest Reims, as *Durocortorum*, was capital of the Remi, from whose name that of the town was subsequently derived. The Remi made voluntary submission to the Romans, and by their fidelity secured the special favour of their conquerors. Christianity was established in the town by the middle of the 3rd century, at which period the bishopric was founded. The consul Jovinus, an influential supporter of the new faith, repulsed the barbarians who invaded Champagne in 356; but the Vandals captured the town in 406 and slew St. Nicasus, and Attila afterwards put it to fire and sword. Clovis, after his victory at Soissons (486), was baptized at Reims in 496 by St. Remigius. Later kings desired to be consecrated at Reims with the oil of the sacred phial which was believed to have been brought from heaven by a dove for the baptism of Clovis and was preserved in the abbey of St. Remi. Meetings of Pope Stephen III. with Pippin the Short, and of Leo III. with Charlemagne, took place at Reims; and here Louis the Débonnaire was crowned by Stephen IV. Louis IV. gave the town and countship of Reims to the archbishop Artaldus in 940. Louis VII. gave the title of duke and peer to William of Champagne, archbishop from 1176 to 1202 and the archbishops of Reims took precedence of the other ecclesiastical peers of the realm.

In the 10th century Reims had become a centre of intellectual culture, Archbishop Adalbero, seconded by the monk Gerbert (afterwards Pope Sylvester II.), having founded schools where the "liberal arts" were taught. Adalbero was also one of the prime authors of the revolution which put the Capet house in the place of the Carolingians. The most important prerogative of the archbishops was the consecration of the kings of France—a privilege which was exercised, except in a few cases, from the time of Philip Augustus to that of Charles X. Louis VII. granted the town a communal charter in 1139. The treaty of Troyes (1220) ceded it to the English, who had made a futile attempt to take it by siege in 1260; but they were expelled on the approach of Joan of Arc, who in 1429 caused Charles VII. to be consecrated in the cathedral. A revolt at Reims, caused by the salt tax in 1461, was cruelly repressed by Louis XI. The town sided with the League (1585), but submitted to Henry IV. after the battle of Ivry. In the foreign invasions of 1814 it was captured and recaptured; in 1870-71 it was made by the Germans the seat of a governor-general and impoverished by heavy requisitions.

Reims suffered severely during World War I. The town was heavily bombed by the Germans in September 1914, and the population took shelter in the huge subterranean wine cellars, occupying old chalk quarries, where dormitories were made, schools were held and a daily paper was published. In 1917 the civilian population which remained was evacuated; in 1918 the town was one of the objectives of the Germans, but it was held until freed by the Allied offensive in October. Reims was then in ruins, and the cathedral was severely damaged, especially on the southwest side. The work of restoration of the cathedral, to the cost of which there was a large American contribution, took many years to complete. The statue of St. Joan of Arc, which stood in front of the cathedral, was removed during World War I for safety and replaced in 1921; many of the art treasures, tapestries, etc., were also saved.

The oldest monument in Reims is the Mars Gate (so called from a temple to Mars in the neighbourhood), a triumphal arch 108 ft. in length by 43 ft. in height, consisting of three archways flanked by columns. It is popularly supposed to have been erected by the Remi in honour of Augustus when Agrippa made the great roads terminating at the town, but probably belongs to

the 3rd or 4th century. In its vicinity a curious mosaic, measuring 35 ft. by 26, with thirty-five medallions representing animals and gladiators, was discovered in 1860. To these remains must be added a Gallo-Roman sarcophagus, said to be that of the consul Jovinus and preserved in the archaeological museum in the cloister of the abbey of St. Remi.

The cathedral of Notre Dame, where the kings of France used to be crowned, replaced an older church (burned in 1211) built on the site of the basilica where Clovis was baptized by St. Remigius. The cathedral, with the exception of the west front, was completed by the end of the 13th century. That portion was erected in the 14th century after 13th-century designs—the nave having in the meantime been lengthened to afford room for the crowds that attended the coronations. In 1481 fire destroyed the roof and the spires. The façade was one of the most perfect masterpieces of the middle ages. The three portals are laden with statues and statuettes. The central portal, dedicated to the Virgin, was surmounted by a rose-window framed in an arch itself decorated with statuary. The rose-window, the statue of the smiling angel, the still more famous "Beau Dieu" statue were all severely damaged in World War I. The gallery of the kings above the rose-window survived but the angel spire was destroyed.

The archiepiscopal palace, built between 1498 and 1509, and in part rebuilt in 1675, was almost completely destroyed. The church of St. Remi (11th, 12th, 13th and 15th centuries) still retains intact its façade and two Romanesque towers; the nave and choir were ruined, and the mausoleum of St. Remigius (1847), containing the reliquary of the saint, behind the high altar, had to be reconstructed.

Reims is the seat of an archbishop, a court of assize and a sub-prefect, and a tribunal and a chamber of commerce. It is an important centre for the combing, carding and spinning of wool and the weaving of flannel, merino, cloth and woollen goods of all kinds. The manufacture of and trade in champagne are also very important. The wine is stored in large cellars tunnelled in the chalk. Other manufactures are linoleum, safes, capsules, bottles, casks, candles, soap and paper. The town is well known for its cakes and biscuits.

REINACH, JOSEPH (1856–1921), French author and politician, was born in Paris on Sept. 30, 1856. After leaving the Lycée Condorcet he was called to the bar in 1887. He attracted the attention of Gambetta by articles on Balkan politics published in the *Revue bleue*, and in Gambetta's *grand ministère* Reinach was his secretary. In the *République française* he waged a steady war against General Boulanger which brought him three duels, one with Edmond Magnier and two with Paul Déroulède. Between 1889 and 1898 he sat for the Chamber of Deputies for Digne. He brought forward many reform bills, advocated complete freedom of the theatre and the press, the abolition of public executions, and denounced political corruption. But he is best known as the champion of Captain Dreyfus. At the time of the original trial he attempted to secure a public hearing of the case, and in 1897 he allied himself with Scheurer-Kestner to demand its revision. He denounced in the *Sicéle* the Henry forgery, and Esterhazy's complicity. His articles in the *Sicéle* aroused the fury of the anti-Dreyfusard party, especially as he was himself a Jew and therefore open to the charge of bias. He lost his seat in the Chamber of Deputies, and, having refused to fight Henri Rochefort, eventually brought an action for libel against him. Finally, the "affaire" being terminated and Dreyfus pardoned, he undertook to write the history of the case, the first four volumes of which appeared in 1901. This was completed in 1905. In 1906 M. Reinach was re-elected for Digne. He died in Paris on April 18, 1921.

SALOMON REINACH (1858–1932), born at St. Germain-en-Laye on Aug. 29, 1858, brother of Joseph Reinach (*q.v.*), was educated at the École Normale Supérieure, and joined the French school at Athens in 1876. He made valuable archaeological discoveries at Myrina near Smyrna in 1880–82, at Cyne in 1887, at Thasos, Imbros and Lesbos (1887), at Carthage and Meninx (1888–89), at Odessa (1902) and elsewhere. He received in 1886 an appointment at the National Museum of Antiquities at St.

Germain; in 1893 he became assistant keeper, and in 1902 keeper of the national museums. In 1903 he became joint editor of the *Revue archéologique*, and in the same year officer of the Legion of Honour. The lectures he delivered on art at the École du Louvre in 1902–3 were published by him under the title of *Apollo*.

His other works include: *Manuel de philologie classique* (1880–1884); *La Néropole de Myrina* (1887), written with E. Potier; *Répertoire de la statuaire grecque et romaine* (3 vols., 1897–98); *Répertoire de peintures du moyen âge et de la Renaissance 1280–1580* (1905, etc.); *Répertoire des vases peints grecs et étrusques* (1900). In 1905 he began his *Cultes, mythes et religions*; and in 1909 he published a general sketch of the history of religions under the title of *Orpheus*.

REINCARNER: see METEMPSYCHOSIS.

REINDEER, a large Arctic and sub-Arctic deer, the American species of which is called caribou. The reindeer constitutes the

BY COURTESY OF THE U.S. ZOOLOGICAL SOCIETY

REINDEER (RANGIFER TARANDUS) It inhabits Arctic and sub-Arctic regions.

The type of the genus (*R. tarandus*) is the Scandinavian wild reindeer. In America the barren ground caribou are forms of the old world species. The woodland caribou (*R. caribou* and *R. novae-terrae*) are other species. All caribou move around and many herds undertake great migrations in the spring and autumn. A small species (*R. platyrhynchus*) inhabits Spitzbergen and Novaya Zembla.

The reindeer has been domesticated by the Lapps and introduced as a domestic animal into Arctic Canada and Alaska. Reindeer feed largely on lichens, one species of which is the so-called "reindeer moss." The brow-tine is not used to scrape away snow; this is done with the hoofs, the horns being shed before spring.

REINDEER MOSS (*Cladonia rangiferina*), a species of lichen found in great abundance in Arctic lands. It is an erect, much branched plant, a few inches in height, which covers immense areas somewhat in the manner of pasture grasses in the temperate regions. In many districts it forms the chief food of the reindeer, and it also provides forage for the barren-ground caribou and the musk-ox. (See *LICHENS*.)

REINECKE, CARL HEINRICH CARSTEN (1824–1910), German composer and pianist, was born at Altona, June 23, 1824. He studied music with his father, with Mendelssohn and with Schumann. From 1845–48 he was court pianist to Christian VIII of Denmark and later taught until 1860, when he became conductor of the Leipzig Gewandhaus, a post he held for 35 years. He died in March 1910. His piano playing was characterized by grace and neatness and at one time he was probably unrivalled as a Mozart player and an accompanist. He wrote a grand opera, *König Manfred*, a comic opera, *Auf hohen Befehl*, a cantata, *Hakon Jarl*, and an overture, which were once frequently played but his most valuable works were those written for educational purposes.

REINFORCED CONCRETE: see FERRO-CONCRETE.

REINFORCED GLASS: see GLASS, SAFETY.

REINHARDT, MAX (1873–1943), Austrian theatrical producer, was born in Baden, near Vienna, Austria, on Sept. 9, 1873. He was educated at the Untergymnasium and later studied for

the stage under Emil Burde, and at the School of Acting of the Vienna Conservatorium (1890). He began his professional career in 1893 at the Stadt theatre in Salzburg, where his characterization of elderly rôles attracted the attention of Otto Brahm, who engaged him for the Deutsches theatre, Berlin, in 1894. There he met with notable success, creating such rôles as Baumer in Hauptmann's *The Weavers*; Akim in Tolstoy's *The Power of Darkness*; Engstrand in Ibsen's *Ghosts*; and many others. In 1903 he left the Brahm ensemble to begin his career as a director at the Neues theatre, Berlin, with the production of Shakespeare's *A Midsummer Night's Dream*, in which he assumed leadership of the neo-romantic movement against the prevailing school of naturalism. He soon transferred his activities to the Deutsches theatre, where he subsequently produced practically all the plays of Shakespeare, Molière, Goethe, Strindberg, Wedekind, Ibsen, Shaw and others, as well as musical comedies and operas, turning from the purely literary and historical conception of stage management to one essentially dramatic. In 1902, he opened his Kleines theatre, and in 1906 his Kammerspielhaus. He first produced *The Miracle* in 1911. After resigning from the Kammerspielhaus in 1932, he went to the U.S.A., where he produced a film version of *A Midsummer Night's Dream* (1935), Franz Werfel's *The Eternal Road* (1937) and *Rosolinda*, based on Johann Strauss' *Die Fledermaus*. He became a U.S. citizen in 1940. He died in New York city, Oct. 31, 1943. See *Max Reinhardt and His Theatre*, ed. Oliver M. Saylor (1924).

REINKENS, JOSEPH HUBERT (1821-1896), German Old Catholic bishop, was born at Bartscheid, near Aix-la-Chapelle on March 1, 1821. He became professor of ecclesiastical history at Breslau, and in 1865 rector of the university. In 1870, Reinkens opposed the proclamation of the dogma of papal infallibility. He signed the Declaration of Nuremberg in 1871, and took a conspicuous part in the Bonn conferences with the Orientals and Anglicans in 1874 and 1875. The Old Catholics having decided on secession, Reinkens was chosen their bishop in Germany at Cologne in 1873 (see OLD CATHOLICS). His best-known theological work is his treatise on Cyprian and the Unity of the Church (1873). In 1881 Reinkens visited England, and in 1894 he defended the validity of Anglican orders against his co-religionists, the Old Catholics of Holland. He died at Bonn on Jan. 4, 1896. See *Joseph Hubert Reinkens*, by his nephew, J. M. Reinkens (Gotha, 1906).

REINSURANCE. Reinsurance is the term used to denote the transaction whereby a person who has insured a risk insures again a part or the whole of that risk with another person. The purpose of reinsurance is to relieve the original insurer from a liability which is too heavy for him to carry. There is no privity of contract between the reinsurer and the original insured, so that the latter could not sue the former to recover any part of a loss, but the insured could recover in respect of a loss against the original insurer up to the full amount of the policy, notwithstanding that part of it had been reinsured.

In a reinsurance transaction the company which reinsures is called the ceding company, the accepting company is called the reinsurer, and the transaction itself is termed a cession.

It is not known when reinsurance was first practised, though there is evidence of its existence at least as early as the first half of the 18th century. In the early days of insurance insurers did not, as a rule, insure for greater amounts than they were prepared to keep for themselves, and, even when this rule began to be relaxed, the arrangements whereby they relieved themselves of heavy commitments partook more of the nature of co-insurance than of reinsurance. Under such arrangements the original insured was in contractual relationship with each of the insurers.

However, in marine business reinsurance was known nearly 200 years ago, for in 1746 an act of parliament made it illegal, a prohibition which was not raised until 1864. It is thought by some that the Act of 1746 really prohibited double insurance; i.e., where the insured covered his property twice, but the word used in the act is "reassurance." However this may be, it is certain that the growth of reinsurance in various sections of the business was slow until well into the 19th century, and it is only during the past 30 years or so that it has developed into its

present important and widespread position.

Reinsurance may be divided into two main branches:—**Facultative (or optional) and Treaty (or automatic or obligatory).**

Facultative Reinsurance.—This was the original form. By this method each risk is offered for reinsurance separately and the ceding company has a free choice as to where it will offer the business. Similarly the reinsurer has freedom to accept or decline. The term facultative is derived from the power of choice, which this method implies. This system of reinsurance is cumbersome, as each risk insured has to be handled separately. The particulars of the risk are first shown to the reinsurer on a slip, which it initials for the share it is prepared to accept. This is followed by a request note; i.e., a formal demand issued by the ceding company to the reinsurer for the specified reinsurance. Upon this the reinsurer issues its take note, which is its official acceptance pending the issue of a reinsurance policy. This last is the final stage in the transaction, and forms the contract between the parties in respect of the risk reinsured.

The facultative system served its purpose at a time when insurance was transacted on a small scale, and when the need for reinsurance cover was neither great nor urgent. But the need arose in course of time for some more efficient method, and this was eventually found in the reinsurance treaty.

Reinsurance by Treaty.—A treaty is an obligatory arrangement, under which the ceding company binds itself to cede, and the reinsurer binds itself to accept, a fixed share of every risk, of a nature as defined in the contract, which the ceding company has to reinsure. A treaty, therefore, provides not for the reinsurance of an individual risk, but for all the risks of a given class. The power of choice is here eliminated. The two parties are reciprocally bound, one to cede and the other to accept.

This is an advantage to both, since the ceding company knows in advance that it can place the reinsurances and the reinsurer can rely on receiving a regular flow of business under the treaty. It is a condition of all treaties that, as soon as a reinsurance is placed thereunder the reinsurer's liability commences from the same moment as the liability of the ceding company, while the obligation to cede prevents the ceding company placing some of its reinsurances with one reinsurer and some with another, or favouring one at the expense of another. In both these particulars reinsurance by treaty differs from and represents a considerable advance over the older facultative method.

It is extremely rare for a ceding company to place a treaty with only one reinsurer, for this would be to entrust too great a responsibility to one undertaking. It is therefore customary to arrange a treaty so that a number of reinsurers share in it, each accepting only a proportionate part of the business ceded.

There are three kinds of reinsurance treaty in general use:—**Quota-share or Open Treaties; Surplus Treaties; and Excess of Loss Treaties.**

Quota-Share Treaty.—A quota-share treaty is one under which the ceding company agrees to cede a fixed share of every risk which it accepts from its clients. There is a necessary tendency for reinsurance business to comprise risks of a second class nature, since the better the risk the more the ceding company keeps for itself. But in a quota-share treaty this feature is not present. Every risk must be reinsured, whether it be good or bad, large or small. For this reason the quota-share treaty is not greatly used, except by small companies, which can obtain sound reinsurance cover only by offering attractive terms.

Surplus Treaty.—The surplus treaty is that in common use. Under this the ceding company first fixes the amount it will keep, which is called its retention, and the remainder of the amount insured constitutes the surplus. This is divided amongst the treaty reinsurers according to their due proportion. The whole surplus is usually divided into percentages, each reinsurer taking 1% or more as agreed of every surplus. But the amount which can be ceded is always governed by the ceding company's retention.

Excess of Loss Treaty.—An excess of loss treaty is an agreement under which no part of any individual risk is reinsured, but the ceding company arranges to cover only the excess of any one

loss over and above an agreed figure. This is a treaty to guard against catastrophe. A ceding company may arrange to cover itself by reinsurance against the excess of loss over £50,000 in respect of any one fire, the cover to run, say, up to £100,000; i.e., a further £50,000. Then if one fire results in a loss to that company of £50,000, or less, the reinsurers pay nothing, but if the cost of the fire exceeds that figure the reinsurers pay the amount of the excess, according to their agreed proportions. This kind of treaty is largely used in motor insurance; but in fire insurance its use is a modern development. In that branch it is operated independently of and in addition to the surplus treaty. The ceding company must still use its surplus treaty to limit its liability on individual risks, taking out an excess of loss cover only to protect itself against heavy conflagrations.

Conditions of Reinsurance.—The conditions applying to a reinsurance are, as a rule, the same as those which apply to the original insurance. Thus the reinsurer receives the same rate of premium and must pay its proportionate share of any claim. There are, however, exceptions to this rule. Under an excess of loss treaty the reinsurer receives no specific premium, but is paid a percentage of the total premium income derived by the ceding company from the class of business to which the treaty applies. In marine reinsurance there is a practice to reinsure risks which are affected by a possibility of loss, and in such cases much higher premium may be paid than under the original policy.

The share of premium payable to the reinsurer is subject to a deduction of commission, which varies from 20% to 35% or, in rare cases, 40% or 45%. Reinsurance commission has to cover not only the agent's commission paid on the original insurance, but also a part of the ceding company's expense of obtaining and dealing with the business. The rate of reinsurance commission depends partly on the level of the expense of dealing with the business and partly on the quality of the treaty. Treaties giving consistently good results can command better terms than poor treaties. As well as commission deducted from premium, the reinsurer has to pay a commission—usually 10%—on the profits. In this way the profitable treaty automatically receives better terms than the bad one. The profit on a treaty is computed after making due provision for all claims and liabilities outstanding at the end of the year. The commission is payable on the average of the profit of the year of account, and of the two preceding years, so that a reinsurer shall not be required to pay away part of its profits in a year which follows a year showing a heavy loss.

The reinsurer, being liable to pay its share of all losses, is entitled to a like share of any amounts recovered as salvage. The ceding company has the control of all loss settlements and may settle a loss or contest a claim as it thinks fit. The reinsurer is bound to follow the fortunes of the ceding company in this matter.

Disputes arising between the parties to a reinsurance treaty, as to any matter coming thereunder, are almost invariably settled by arbitration.

Bordereaux.—Particulars of cessions made under a treaty are advised by the ceding company to the reinsurer by means of bordereaux. A bordereau is a statement giving the name and address of the insured, the nature of the risk, the sum insured, the premium, the amount reinsured and the reinsurance premium. No reinsurance policies are issued under treaties, as the reinsurance cover operates under the treaty contract. In marine business, however, properly stamped policies have to be issued even for reinsurance, under the provisions of the Stamp Act, 1891, and the Marine Insurance Act, 1906.

Retraction.—A reinsurer, receiving particulars of its cessions by bordereaux, will itself deal with the business so received, and will in its turn arrange treaties to cede off its own surplus lines. A reinsurance of a reinsurance is called a retraction. Retraction is an important part of reinsurance business because where a reinsurer has a share of many treaties it will frequently receive a share of the same risk under many of its different treaties and must needs relieve itself by retraction of the accumulation of risk. (C. E. G.)

United States.—The U.S. reinsurance business grew rapidly

during the 20th century. As in the European countries facultative and the three kinds of treaty insurance are used, but the percentage of facultative is rapidly diminishing because of delay and uncertainty.

What may be called a variation of the fixed treaty is the "pool" or "syndicate." Here as many as 35 companies will enter into an agreement to share all insurance in a given territory on a basis of certain agreed proportions both in regard to premiums and losses.

In order to facilitate the placing of reinsurance and to bring about greater uniformity of practice, reinsurance clearing houses or exchanges were established. Here the detailed reinsurance agreement is subscribed to by the member companies who are all represented by a manager.

Many of the life insurance companies continued to use the facultative plan of reinsurance.

There are two ways of reinsuring. The smaller companies will reinsure the amount at risk with term insurance. Most of the larger companies use the coinsurance plan, whereby the reinsurance company receives a proportionate part of the premium and guarantees a proportionate part of all payments including expenses and taxes.

There are many insurance companies whose business is entirely reinsurance. (R. RET. X.)

REISKE, JOHANN JACOB (1716-1774), German scholar and physician, was born on Dec. 25, 1716, at Zörbig in Electoral Saxony. From the Waisenhause at Halle he passed in 1733 to the university of Leipzig, and there spent five years. He bought Arabic books, and when he had read all that was then printed he thirsted for manuscripts, and in March 1738 started on foot for Hamburg. At Hamburg he got money and letters of recommendation from the Hebraist Wolf, and took ship to Amsterdam. Reiske refused a generous offer from d'Orville at Amsterdam for his services as amanuensis. Ultimately he got free access to the Leiden collection, which he re-catalogued—the work of almost a whole summer, for which the curators rewarded him with nine guilders. D'Orville and Schultens helped him to find teaching and reading for the press. On the advice of Schultens he qualified as a doctor, after which, in 1746 he returned to Leipzig.

But he failed to secure any medical practice at Leipzig, and lived, as before, on ill-paid literary hack work. Although the electoral prince gave him the title of professor he was not permitted to lecture. At length in 1758 the magistrates of Leipzig rescued him from poverty by giving him the rectorate of St. Nicolai, and, though he still met with hostility in the university, he enjoyed the esteem of Frederick the Great, of Lessing, Karsten Niebuhr, and many foreign scholars. The last decade of his life was made cheerful by his marriage with Ernestine Müller, who shared all his interests and learned Greek to help him with collations. Reiske died on Aug. 14, 1774, and his ms. remains passed, through Lessing's mediation, to the Danish minister Suhm, and are now in the Copenhagen library.

Reiske surpassed all his predecessors in the range and quality of his knowledge of Arabic literature. In the *Adnotationes historice* to his *Abulfeda* (*Abulf. Annales Moslemici*, 5 vols., Copenhagen, 1789-91), he collected a veritable treasure of sound and original research; he knew the Byzantine writers as thoroughly as the Arabic authors, and was alike at home in modern works of travel in all languages and in ancient and mediæval authorities. He was interested too in numismatics, and his letters on Arabic coinage (in Eichhorn's *Repertorium*, vols. ix.-xi.) form, according to De Sacy, the basis of that branch of study.

In Leipzig Reiske worked mainly at Greek. His corrections are often hasty and false, but a surprisingly large proportion of them have since received confirmation from MSS. His German translations shew more practical insight than was usual in his time.

For a list of Reiske's writings see Meusel, xi. 192 seq. His chief Arabic works (all posthumous) have been mentioned above. In Greek letters his chief works are *Constantini Porphyrogeniti libri II. de ceremoniis quibus Byzantii*, vols. i. ii. (Leipzig, 1751-66), vol. iii. (Bonn, 1899); *Anecdota, ad Græcos auctores* (4 vols., Leipzig, 1751-66) (the rest lies unprinted at Copenhagen); *Oratorum Græcæ quæ supersunt* (8 vols., Leipzig, 1770-73); *App. crit. ad Demosthenem* (3 vols., ib.,

1774-75); *Maximus Tyr.* (ib., 1774); *Plutarchus* (11 vols., ib., 1774-79); *Dionysus Ilic.* (6 vols., ib., 1774-77); *Libanius* (4 vols., Altenburg, 1784-97). Various reviews in the *Acta eruditiorum* and *Zuerli. Nachrichten* are characteristic and worth reading. Compare D. Johann Jacob Reikens *von ihm selbst aufgesetzte Lebensbeschreibung* (Leipzig, 1781).

REITH, JOHN CHARLES WALSHAM REITH, 1ST BARON, OF STONEHAVEN (1880-), British civil engineer, served in the royal engineers during World War I. He was director-general of the British Broadcasting corporation (1927-38), first chairman of the British Overseas Airways corporation (1930-40), minister of information (1940) and director of the combined operations material department for the admiralty during World War II (1943-45), and became chairman of the Commonwealth Communications council in 1946. He was created baron in 1940.

RÉJANE, GABRIELLE (CHARLOTTE RÉJY) (1857-1920), French actress, was born in Paris and made her debut in 1875. Her first great success was in Henri Meilhac's *Ma camarade* (1883), and she soon became known as an emotional actress of rare gifts, notably in *Décors*, *Germinie Lacerteux*, *Ma cousine*, *Amoureuse* and *Lysistrata*. Her performances in *Madame Sans Gêne* (1893) made her as well known in England and America as in Paris, and in later years she was particularly successful in *Zaza* and *La Passerelle*. She opened the Théâtre Réjane in Paris in 1906. She died on June 14, 1920.

REJANG, a tribe of Proto-Malayan or mixed Indonesian stock, partly akin to the Achinese, Bugis (qq.v.) and Mangkasaras. Though now Muslim they were formerly influenced by Indo-Javanese culture and retain an alphabet derived from that source, speaking a language of the Austronesian family. Their alphabet has been described as "pure Phoenician," but is intimately related to others derived from the Indo-Javan culture. Ideas of ancestor-worship are strong, and metempsychosis (g.v.) is vaguely believed in, tigers in particular being regarded as embodying the souls of the dead. Worship of the sea also prevails. It is believed that invulnerability can be acquired. Teknomy is practiced, and persons object to mentioning their own names. The dead are buried in a chamber excavated to one side of the grave. Betel is chewed. In blood-tariffs the value of a woman is nearly double that of a man except in the case of chiefs, only the highest of whom are rated higher than their wives.

See Marsden, *History of Sumatra* (1783).

(J. H. H.)

REJERA, the Spanish form of open-work screens made from combinations of wrought and cast iron work. The word *reja* is used for a screen, individually; *rejera* properly signifies this whole class of iron work. A magnificent example is the *reja* of the Capilla Mayor of Seville cathedral (1518-33). Many beautiful examples of this type are found as window guards in Spanish Renaissance houses.

REJUVENATION. In all multicellular animals the process of regeneration, growth and rejuvenation is constant as is shown typically by the hair and nails. It is now possible to cultivate tissues in suitable media (see *TISSUE CULTURE*) and to keep them alive long after the death of the parent organism. This proves that death is not the inevitable end of cellular vitality, but is in every case the result of unfavourable conditions to which the cells are subjected at a given moment.

The endocrine glands produce substances (hormones), which they pour into the circulatory system and thereby influence the metabolic processes, the growth and morphology of the cells. One of these glands should have as its special function the secretion of a substance which gives tone and stimulus to cellular vitality during a certain period of life and ceases to do this on the approach of old age. This cannot be the special function of the thyroid, parathyroid, pituitary or suprarenal glands, since they continue to act during old age. The only gland which constitutes an exception to this rule is the genital gland. It plays a double rôle. It secretes spermatozoa externally, and it secretes internally hormones which it passes into the blood stream, actively at puberty and during maturity, but less and less thereafter, so that the diminution and disappearance of its activity correspond with old age.

Examination of male vertebrate animals, including man, after

removal of the genital glands shows distinctly the nature of the influence of the internal secretion of these glands on the whole organism as affecting, not only the secondary male sexual characters, but also the growth and development of the body as a whole, the brain and skin cells, the bones and tissues. The physical and intellectual qualities of animals and of man are as intimately conditioned by the hormone secreted by the testicles as are the secondary sexual characters.

There can thus be no doubt as to the nature of the relation between the general reduction of the forces of the organism and the disappearance of the internal secretion of the testicles. No organ can keep its vital energy and yield a full return if the cells are not stimulated and vivified by the testicular hormone. It acts more or less directly on other endocrine glands, since castration is followed by hypertrophy of the anterior lobe of the pituitary gland and by regression of the thyroid body and epiphysis. If the genital glands remained active in old age, were they not the only glands which cease to secrete hormones, old age would certainly be delayed.

Eunuchs in Cairo who had been castrated at an early age and had therefore never been exposed to the activity of the testicular hormones, were never known to have been more than 60 at death. All had the appearance of old men, with desiccated skins, haggard eyes, bent, and looking like centenarians.

It is obvious that the deprivation of the internal secretion of the testicles accelerates the advance of old age and shortens life. The only remedy is to graft a young testicle, whether that of a young human being or of an ape, by which the tone-giving substance is provided, so as to increase the vitality of all the cells which are weakened but are not yet atrophied and therefore still able to renew themselves, and thus effectively to rejuvenate the whole organism. So long as an organism, however old, continues to exist, its cells continue to be renewed and rejuvenated. Unfortunately, in old age this process of rejuvenation is slowed down, a certain number of the functional cells regress and are replaced by conjunctive tissue. The cells which escape this are renewed more slowly, but continue to be renewed to the extreme limit of their vitality.

With a rich addition of the testicular hormone, the cells acquire new energy, grow more rapidly, proliferate more intensely and rejuvenate the whole system. At the end of several years the beneficent action of the grafted gland is exhausted because the grafts in turn are subject to positive regression. The organism is again deprived of the stimulating hormones and the symptoms of old age reappear. In most cases testicular grafting is adequate, but in some cases thyroid grafts have to be added. See S. Voronoff, *Rejuvenation by Grafting* (1925) (S. V.)

RELANDER, LAURI KRISTIAN (1883-1942), president of Finland, born May 31, 1883, and educated at Helsingfors university. He was a member of the central committee of the agrarian party in 1909, sat in the diet from 1910 to 1913, and 1917-19, when he became its speaker. From 1925 to 1931, he was president of the republic. He died Feb. 9, 1942.

RELAPSING FEVER (*Febris recurrens*), the name given to a specific infectious disease occasionally appearing as an epidemic in communities suffering from scarcity or famine. It is characterized mainly by its sudden invasion, with violent febrile symptoms, which continue for about a week and end in a crisis, but are followed after another week, during which the patient is fairly well, by a return of the fever. In exceptional cases, second, third and even fourth relapses may occur.

This disease has received many other names, the best known of which are famine fever, seven-day bilious relapsing fever, and spirillum fever. Like typhoid, relapsing fever was long believed to be simply a form of typhus. The distinction between them appears to have been first clearly established in 1826, in connection with an epidemic in Ireland.

In 1873 Obermeier discovered in the blood of persons suffering from relapsing fever minute spiral filaments of the genus *Spirillum*, having rotatory or twisting movements. This organism received the name of *Spirillum obermeieri*. Fritz Schaudinn brought forward evidence that it is an animal parasite. Relapsing

fever is most commonly met with in the young. One attack does not appear to protect from others, but rather, according to some authorities, engenders liability. The incubation of the disease is about one week.

The mortality in relapsing fever is comparatively small, about 5% being the average death-rate in epidemics (Murchison). The fatal cases occur mostly from the complications common to continued fevers. The treatment is essentially the same as that for typhus fever. Löwenthal and Gabritschewsky by using the serum of an immune horse succeeded in averting the relapse in 40% of cases.

RELATIONSHIP TERMS. Relationship terms are studied by the anthropologist not merely as so many words inviting philological analysis and comparison, but as correlates of social custom. Broadly speaking, the use of a specific kinship designation, e.g., for the maternal as distinguished from the paternal uncle, indicates that the former receives differential treatment at the hands of his nephews and nieces. Further, if a term of this sort embraces a number of individuals, the probability is that the speaker is linked to all of them by the same set of mutual duties and claims, though their intensity may vary with the closeness of the relationship. Sometimes the very essence of a social fabric may be demonstrably connected with the mode of classifying kin. Thus, kinship nomenclature becomes one of the most important topics of Social Organization.

In the daily routine of savage life, relationship terms are not only important as at once ticketing the status of the person addressed or mentioned with reference to the speaker, but also because often there is no other mode of address. This is because of the widespread prejudice against the vocative use of personal names, for which accordingly kinship appellations are substituted, even to the extent of assuming a relationship where none exists.

CLASSIFICATION OF KINSHIP TERMINOLOGIES

The foundation of the scientific study of this subject was laid by Lewis H. Morgan in his *Systems of Consanguinity and Affinity of the Human Family* (Smithsonian Contributions to Knowledge, XVII, Washington, 1871). In this great work were assembled comprehensive schedules for every major area of the globe except Africa and Australia, for which data were largely or wholly inaccessible to the author. Morgan grouped all terminologies under two main heads—the descriptive and the classificatory. The descriptive system, ascribed to the Aryan, Semitic and Uralian families, “describes collateral consanguineal, for the most part, by an augmentation or combination of the primary terms of relationship” (pp. 12, 468). The classificatory system never describes consanguineal by a combination of primary terms but ranges them into great classes or categories: “All the individuals of the same class are admitted into one and the same relationship, and the same special term is applied indiscriminately to each and all of them” (p. 143). Two varieties of the classificatory type were recognized—the Malayan, which merged all kindred of one generation irrespective of proximity in one category; and the Turanian-Ganowanian, in which only some of the collateral kin of a generation were merged with the lineal, the remainder being separated by distinctive terms.

This dichotomy is unacceptable. As Kroeber¹ and Rivers² remark, our words for uncle, aunt and cousin likewise range consanguineal into large classes, so that the absoluteness of the distinction breaks down. Furthermore, Rivers notes that “descriptive” does not strictly apply to the English and related terminologies, which rarely augment or combine the primary terms. That epithet may be properly reserved for such Norwegian words as *farbror* and *morbror* for father’s and mother’s brother, respectively; and hence for certain nomenclatures, e.g., the Arabic, which largely employ expressions of this order. Thus, Rivers supplanted Morgan’s dualism with a tripartite scheme, recognizing denotative, descriptive and classificatory types. Elsewhere he suggests the

¹A. L. Kroeber, “Classificatory Systems of Relationship,” *Journal Royal Anthropol. Instit.*, 1909, 39: 77-84.

³Ibid., article “Kin, Kinship” in Hastings’ *Encyclopaedia of Religion and Ethics*.

appellations family, kindred and clan systems, the “kindred” being a major bilateral unit.⁴ These latter terms are, however, objectionable since they inject the inferential basis of a system into its descriptive definition. There are classless tribes with clan systems in Rivers’ sense, and the result would be confusion. Apart from this terminological difficulty, the scheme fails to obviate a logical fault in Morgan’s earlier effort. “Descriptive” and “classificatory” do not relate to the same logical universe, hence are not complementary terms. “Classificatory” relates to the number of individuals defined, “descriptive” to the technique of defining a relationship. It is possible to augment or combine primary terms and then apply the resultant to an indefinitely large class of persons. The antithesis to “classificatory” is the concept “individualizing,” as Morgan felt, though he failed to express it.

But the purging of the traditional terminology does not carry us very far. How shall we characterize our simple English system if it embodies both individualizing and classificatory principles? The answer is provided in Kroeber’s above-cited essay: a kinship terminology is not a logically coherent whole but must be resolved into the several categories recognized. Those enumerated by Kroeber are: the difference of generations; the difference between lineal and collateral kin; the difference of age within one generation; sex; the speaker’s sex; the connecting relative’s sex; the difference between consanguinity and affinity; and the life or death of the connecting relative.

This pioneer attempt requires both revision and amplification. The last mentioned feature, e.g., is of purely local significance in western North America and of limited application where found. The differentiation between elder and younger sibling (brother or sister) means psychologically simply the intercalation of two additional generations. On the other hand, the reciprocity principle, linking by a common term distinct generations, merits independent status. Cognizance must also be taken of the frequent duplication of terms in address and mere reference, the mode of classification itself sometimes differing. Extra-American terminologies also suggest that the categories laid down by Kroeber might be materially increased. Even as it stands, however, his sketch furnishes a valuable instrument for the precise definition and comparison of distinct systems.⁵

In the present state of our knowledge it is impracticable to do more than concentrate upon an unequivocally significant feature as a basis for classification in a world-wide survey, and to refine areally by supplementary characteristics. The trait that obtrudes itself on our notice is the treatment of collateral as compared with lineal kin in the first ascending and descending generations. It is implicitly the phenomenon that impressed Morgan; it has a bearing on Tylor’s and Rivers’ theories (see below); and constitutes one of Kroeber’s categories. Practically, the data usually suffice to characterize systems from this point of view.

The logical possibilities are as follows: (a) Collateral lines are wholly merged in the lineal within a particular generation (generation system); (b) each generation is bisected so that only half the collateral kin are merged in the lineal (bifurcate merging system); (c) the immediate collateral lines are distinguished from the lineal and from each other (bifurcate collateral system); (d) collateral lines are distinguished from the lineal, but not from each other (lineal).

In standard samples of these four systems logical coherence prevails: if the father’s brother is called father, he addresses his brother’s son as son; if there is a separate word for mother’s brother, there is likely to be one for nephew. However, discrepancies occur, and a system must sometimes be classed by the preponderance of its affiliations. Taking the classification of uncles for illustration, the scheme may be illustrated by the table on page 85.

The second system, which Morgan and Rivers genetically connect with the first (though in a reverse sense), is not one whit farther from the third; and the bifurcate collateral system sets off the immediate family as sharply from the rest of the universe as

⁴*Social Organization*, 55 sq.

⁵E. W. Gifford, *California Kinship Terminologies* (Univ. Cal. Pub., vol. 18, 1923).

System	Relatives				Criterion
Generation	Father	Father's Br.	Mother's Br.		One "father" term
Bifurcate Merging	"	"	"	"	Two terms; partial merging
Bifurcate Collateral	"	"	"	"	Three terms; no merging
Lineal	"	"	"	"	Two terms; merging only of collaterals

our English lineal system. All four systems actually occur in primitive communities, notwithstanding the widespread notion that they have only the first two, corresponding to Morgan's classificatory types.

With this provisional scheme it is possible to characterize the main areas of the globe. Since regional summaries are available for Australia and North America, it will be best to begin with these continents.

AUSTRALIA

Australian kinship terminologies follow the bifurcate merging plan.

Certain other traits are characteristic. Among these is the use of separate terms for maternal and paternal grandparents. Thus, the Kakadu in Northern Australia call the father's father *kaga*, but the mother's father *pepi*. With many tribes this trait is coupled with the reciprocity principle: in Arunta, *aranga* designates simultaneously the father's father and the son's child. Again, the world-wide distinction between the speaker's elder and younger siblings often displays refinement, so that in Arunta the father's elder brother's sons are "elder brothers," while the father's younger brother's sons are "younger brothers." More rarely, as among the Mungari, the uncles and aunts themselves are distinguished with reference to their age as compared with the speaker's parents.

While these features have parallels in remote areas, others seem distinctive. According to Radcliffe-Brown, all nomenclatures of the region conform to two types, correlated with distinct forms of marriage law. In type I, as found among the West Australian Kariara and the Urahuna of the Lake Eyre region, the father's father is classed with the mother's mother's brother; by the correlated matrimonial rule a man is prohibited from marrying any woman unless she stands to him in the relation of a mother's brother's daughter. In type II, the mother's mother's brother is distinguished from the father's father, being often classed with the mother's mother; here the prescribed marriage is between the children of two female cross-cousins, a man marrying his mother's mother's brother's daughter's daughter. This second type is of wider distribution than the first, having been discovered among the Dieri, the Central tribes generally, from the Arunta northward to the Anula and Mara, and among such West Australians as the Marudhunera.¹

Probably most of the tribes substitute relationship terms for personal names in ordinary intercourse, but the central Australians only tabu sacred appellations, while secular names are used in address, interchangeably with the kinship terms.²

A feature worth noting is the absence of terms of affinity. This is evidently to be correlated with the fact that in Australia marriage is prescribed with definite blood relatives. Accordingly there is no necessity for coining new words for connections by marriage. This same trait may be expected to occur in greater or lesser degree in other parts of the world where corresponding forms of marriage with blood relatives are either obligatory or at least preferred.

NORTH AMERICA

North America north of Mexico may be split into two main divisions. Among the Eskimo, in southern British Columbia, the Basin states, Washington, Oregon, and part of California, there are predominantly lineal or bifurcate collateral systems; in the remainder of the continent the terminologies are bifurcate merging. These two main areas correspond roughly to a social organization on the family basis and a clan organization, respectively. Two Australian features, the reciprocity principle and the discrimination of maternal and paternal grandparents, occur exclusively, or nearly so, in the Far West. However, they do not appear with bifurcate merging traits.

Primarily on the basis of cousin grouping Spier has established eight varieties of nomenclature.³ The Iroquois type maintains the separation of generations, treats parallel cousins as siblings, and designates cross-cousins by a specific cousin term. The Mackenzie Basin type drops distinctions between cousins, treating all alike as siblings. The Eskimo type resembles the foregoing in merging parallel and cross-cousins, but separates them from siblings. The Omaha systems, embracing several Californian as well as Central tribes, distinguish among cross-cousins. The father's sister's children are regarded as sister's children, which classes them (on bifurcate merging principles) as children if the speaker is a woman. Correlatively, the mother's brother's daughter is classed as a mother, while the mother's brother's son is equated with the mother's brother. In the Crow type the reverse confusion of generations occurs; the father's sister's son is a "father" and addresses his mother's brother's children as his "children"; the father's sister's daughter is a father's sister.

Spier's remaining varieties rest on other principles. His Salish type diverges in displaying lineal features. The Acoma type is segregated by virtue of its three grandparental terms,—one for a man's grandfather, another for a woman's grandmother, a third for a grandparent of the opposite sex. Finally, the Yuman variety is characterized by a refinement of age distinctions,—the father's elder brothers and mother's elder sisters being distinguished from their younger siblings, while parallel cousins are sometimes classed as elder or younger siblings according to their parents' rather than their own ages.

Spier's types avowedly embrace tribes neither geographically nor linguistically close to their eponyms. Thus, the Iroquois type embraces the Iroquois, Ojibwa, Cree, Dakota, some Californian groups, and the Tsimshian of British Columbia.

Based on different principles, Spier's findings (for which he deprecates any interpretation) are not at once wholly convertible into our terminology. However, the Salish case, which he refuses to class by the cousin criterion as of the Mackenzie Basin category, is coextensive with the lineal type. Moreover, both his Omaha and Crow types are varieties of the bifurcate merging type. This, in its classical Seneca form, largely coincides with Spier's Iroquois type, though his stressing of cousin terminology leads to the admission of several tribes who do not merge parents' siblings and parents. In Spier's scheme, the Eskimo are segregated because they use a distinctive cousin term for all cousins. Their separation is undoubtedly warranted. Morgan himself, though describing their system as "classificatory," shows that the nomenclature has "but two, out of ten, of the indicative features of the system of the Ganowanian family" and that "in the greater and most important fundamental characteristics of this system it is wanting."⁴ On Morgan's evidence, the use of individualizing terms for the parents and the segregation of maternal from paternal uncles and aunts, would place the Eskimo under the bifurcate collateral head; more recent data for another local division are confirmatory.⁵

Spier's Acoma and Yuman varieties, logically outside his own scheme, hardly merit separate categories, as he himself admits in the Acoma case.

A summary classification of the North American systems thus leads to the following tentative scheme:

³L. Spier, *The Distribution of Kinship Systems in North America*, Univ. of Washington Pub. in Anthropology, Seattle, 1925, vol. 1, 69-88.

Salish; Nootka, Kwakiutl

Merging
Collateral

Generation system is lacking. Faintly adumbrated, it approaches the speaker's Mackenzie Basin type, but the generation principle is restricted in application, so that there is no approach to the bifurcate system. Various Californian and Basin tribes classed as of the Mackenzie pattern appropriately fall under the bifurcate collateral group, deviating from the norm only in the grouping of cousins. Such tribes as the Northwestern Maidu belong to the same category and show how this may approach the merging type: parallel cousins here coincide with siblings, while cross-cousins are separated by a special term.¹ The gap between the Maidu and the Iroquois system is thus reduced to the distinction, the former maintains between the father and his brother, the other and her sister.

Sporadically, instances occur in otherwise bifurcate merging systems of a partial failure to bifurcate. Thus, the Crow, though in its direct address, use one term for the mother and either and of aunt.

Personal names are generally eschewed in address.

CENTRAL AND SOUTH AMERICA

Central American systems are known mainly through such sources as Gilbert's *Diccionario de la lengua Tarasca* (1559), Molina's *Vocabulario de la lengua Mexicana* (1571), and Beltrán's *Arte del idioma Maya* (1742).² The distinction of elder and younger sibling is general, and so is the use of reciprocal terms between different generations. Thus, Maya *mom* is applied to the maternal grandfather and the daughter's son. The principle of reciprocity occurs among the Miskito of Nicaragua, *dagna* designating father-in-law and son-in-law, as well as mother-in-law and daughter-in-law in female speech. The former classification is shared by the Chibcha of Colombia. In the Ucayali region, the Sipibo apply the word *rayos* to parent-in-law and son-in-law, while the words for maternal uncle and sister's son—*cuca* and *cucu* suggest a common stem.³ In America there is thus a fairly continuous distribution of the reciprocity principle extending from British Columbia through the Pacific and Basin States into Mexico and northern South America.

Several tribes in Latin America recognize to an unusual extent Kroeber's category of the speaker's sex. While a Cakchiquel man calls his son *cahol* and his daughter *mial*, a woman uses *vat* and *vxocot*.

From the scanty material accessible it is not clear how commonly bifurcate merging systems occur south of the Rio Grande. Molina's Nahuatl nomenclature is Hawaiian in grouping all uncles with the father, *tatli*; but it is lineal in segregating aunts, *autil* from the mother, *nantli*, and all nepotric kin as *machtli* from the son *teptitli* and daughter, *teichpuchi*. The Cakchiquel use of *tata* for father and paternal uncle is true to the bifurcate merging type, but the reported classification of the paternal aunt with the mother, *te*, while both maternal aunt and uncle are called *vican* is so anomalous as to call for corroboratory evidence.⁴

Lineal uncle and aunt terms are reported for the Pomeran Awak. On the whole, the frequency of lineal and bifurcate collateral features arrests our attention. Thus, the Miskito, while using for the maternal aunt a word from the stem for mother (*yapti*; mother's sister: *yaptisip*), call the father *aisa*, the paternal uncle *urappia*, the mother's brother *tarti*. A glossary of Arawakan languages shows no discrimination between paternal and maternal uncles except in Siusi; there the bifurcate collateral rather than the bifurcate merging principle obtains since the father's brother is not identified with the father. A single term for aunt (distinct

from mother) indicates either inconsistency or inaccurate reporting.⁵ The Tupi generic terms exist for aunt and uncle (*aise* and *tutya*), but the father term is said to be applicable to all the father's male kin. In short, there is a mingling of lineal and merging features.⁶ More consistently, the Sipibo separate the father, *papa*, from both the father's brother, *eppa*, and the maternal uncle, *cuca*, and similarly segregate the mother from the maternal as well as the paternal aunt (*tita*, *huasta*, *yaya*, respectively; it is not clear to what extent the matter is complicated by the use of separate words by men and women). The Araucanian terminology is in part bifurcate collateral: the father, *chao*, is distinguished from his brother, *malle* and his brother-in-law, *huecu*; while the mother's sister is designated by a derivative from the mother term.⁷

It cannot be denied that there are nomenclatures of the usual "classificatory" type. According to Ruiz de Montoya (1640), the Guarani was of this order.⁸ Nevertheless, the South American tendency toward collateral or lineal usage cannot be ignored.

ASIA

In Asia the wide distribution of status terms expressive of relative seniority is noteworthy, differences of generation being sometimes disregarded, while again the relative seniority of relatives other than those immediately concerned may be significant. The system of the Turkic Yakut of northern Siberia illustrates some of the relevant complications. Radically of the bifurcate merging type, it groups together as *agas* the elder sister and all older women in the speaker's clan, those younger being designated as *babys*, and the words for elder brother are similarly extended. But the seniority idea overrides the generation principle when *ini* designates not only younger brother or cousin within the clan, but also, the father's younger brother and his son; or when *ogom* is applied indifferently to a child, a grandchild, and even to younger people without reference to relationship. Again, while the father's elder brother is called by a derivative from the father term, this same word is extended by the seniority principle to the mother's father; and while *tay* marks off the maternal from the paternal uncles, the mother's sisters are called according to their age with reference to the mother, *tay agas* and *ty babys*. Thus, since the mother is *yd*, there is in so far forth bifurcation without merging.⁹

When the two parental lines are discriminated and the parents' siblings are set off from the parents by mere modifiers of the primary "parent" stem, it seems legitimate to speak of a basically bifurcate merging system. The primitive Sinitic languages in part present this phenomenon and suggest that the proto-Chinese system may have conformed to this model. Its present form is puzzling. Morgan vacillated between calling it Malayan or Turanian, i.e., a generation or a bifurcate merging system. If we stress the specialization of, say, uncles by modifiers rather than the use of a common primary stem, it would be recognized as collateral; otherwise it might rank as a generation system. Some traits however, such as the classing of brother's sons by males indicate bifurcation. It is evident that emphasis on status and seniority would cause a drift from the bifurcate merging toward the generation pattern. Of the primitive members of the Sinitic stock, the Sema, Ao, Angami and Lhota fall rather clearly under the bifurcate merging division, some of them definitely presenting the Omaha variety. Thus, Lhota *omo*, Sema *angu*, Chongli Ao *okhu* mean the maternal uncle and his son; Sema *atikhshu*, Lhota *orho*, and Chongli *anok* refer to the sister's son and the father's sister's son in male speech.

⁴Breton, *loc.*

The complete lack of certain kinship terms in some Assamese tribes is remarkable; in Angami, for example, parallel cousins can be designated only by their personal names. The Chinese may combine such names with the specific kinship terms.¹

Typical nomenclatures of the bifurcate merging type occur among the peoples of Southern India (including the Toda) and the Vedda of Ceylon. Here, and in other tribes of the area showing this pattern in obscured form, the terminology is affected by cross-cousin marriage. Since a Kachin seeks to marry the daughter of his maternal uncle, he calls his father-in-law and his mother's brother alike *isa*; while in Mikir the sister's son and the son-in-law are both a man's *osa*, and the wife's brother is his *ong-so* or "little maternal uncle," in other words, his maternal uncle's son.²

The two Negrito tribes of Southern Asia differ radically inasmuch as in address the Semang of the Malay Peninsula avoid personal names, while the Andamanese use them exclusively. They resemble each other in stressing status in their nomenclature. Indeed, it seems doubtful whether the Andamanese have any true kinship terms. Though a parent may be individualized by prefixing the personal pronoun to an appropriate noun, this by itself expresses no bond of consanguinity but simply the status of being *some one's* parent. Correspondingly, other words denote relative seniority in varying degrees: *mama* extends to all considerably older persons such as grandparents and parents-in-law. The Andamanese nomenclature lacks bifurcation completely and might be treated as a variety of the generation system; this feature, linked with the vocative use of names, suggests affiliation with Polynesia, where however, generation terms are limited to actual kin. The Semang system is not so well known, but bifurcation seems undeveloped. From *ai*, father, designations for *either* parent's elder and younger brother are formed by the addition of age-suffixes; the word for mother with the appropriate suffix means *either* parent's elder sister, while a new stem designates a younger sister of father or mother. We shall not go far wrong in assigning this system also to the generation category.³

In western Asia, the Semitic tribes have been treated as typical of the "descriptive" pattern. As has been shown, the descriptive technique is wholly consistent with a "classificatory" meaning. The Arabic terminology is on the face of it bifurcate collateral. It is partly shaped by the custom of parallel-cousin marriage, so that father's brother and father-in-law are identified in fact and in masculine speech. The absence of a common word for paternal uncle in Semitic languages has suggested the hypothesis, as yet awaiting confirmation, that the proto-Semitic system was of the merging type.⁴

Lineal systems occur in northeastern Siberia among the Koryak and Chukchee, where clans are lacking. Both tribes distinguish younger and elder siblings, and the Chukchee have even a separate term for "middle" brother. The Yukaghir terminology presents disparate features. In a sense, the parents are individualized, the children are set off from nepotism, and the distinction between paternal and maternal uncles indicates a bifurcate collateral system. However, some of the uncle-aunt words are etymological derivatives from the parent terms, suggesting a merging principle. In addition, the seniority principle of the Yakut order plays a large part, putting both grandmothers in the same class with the father's elder sister, both grandfathers with the elder brother. The technique is sometimes denotative, sometimes descriptive. It is plausible to regard this medley as at least partly the result of

distinct culture layers. An archaic system resting on the family may have been complicated by a bifurcate merging system, stressing the seniority idea. In other words, a palae-Asiatic layer may have had Yakut-like accretions.⁵

AFRICA

In the southern half of the continent bifurcate merging systems prevail. The Hottentot nomenclature approximates the Iroquois pattern, though the occasional classification of the mother's brother's son with the maternal uncle marks a deviation in the Omaha direction. For the Bushmen, data are inadequate, though reported suggestions of a "classificatory system" indicate another sample of the Iroquois form. With modifications of a minor character this holds for most of the Bantu. There is little to support Morgan's interpretation that the terminology is "Malayan." His guess that the stem for mother's brother was a recently evolved substitute for the father term is refuted by its occurrence in much the same form among the Thonga and Wayao, while the concept is attested for as far north as Uganda and the Congo. The very fact cited by Morgan that a single word denotes the paternal aunt and the father proves the stress on bifurcation, even to the detriment of sex distinctions. The generation factor doubtless asserts itself in the classification of all cousins with siblings, but this is far from universal in Bantu speech. The Wayao, e.g., distinguish cross-cousins from parallel cousins by a distinctive designation. Moreover, the very essence of the generation principle is ignored by a number of tribes. The Thonga, like the Hottentot, may call the mother's brother's son *malume*, like the maternal uncle, while the daughter of the mother's brother is a "mother," and sometimes the grandchild and the sister's child fail to be distinguished.

Again, the wife's parent and the wife's elder sibling fall into the same Thonga category, and sometimes the grandfather term embraces the maternal uncle. Finally, the Wayao have a reciprocal term for parent-in-law and child-in-law. There is thus no warrant for putting the Bantu with the Polynesians; their system is basically of the bifurcate merging type, modified locally by various causes, sometimes along Omaha lines.⁶

The Hamitic and Hamitoid tribes are generally credited with "descriptive" systems. In fact, the descriptive technique may be employed to an unusual degree, so that the 'Afar of the East Horn call a brother "mother's son." This, however, does not preclude a classificatory meaning for the descriptive designation, much less for other parts of the same nomenclature. Galla *abba*, for example, may be applied not only to the father but as an honorific appellation to any old man. The Somali system is definitely bifurcate collateral. Among the Masai the paucity of genuine kinship terms is no less remarkable than certain correlated usages. While father's and mother's siblings are distinguished from the parents by descriptive phrases, this discrimination extends only to reference, while in address the father's brother is a father. Most kinsmen, however, are not called by terms of consanguinity or affinity but according to the livestock they have received from the speaker: if he has presented a man with a bull (*ainoni*), the beneficiary is called *b-ainoni*, etc. Generations often fail to be separated: *koko* embraces aunt and grandmother, and with a suffix the word is applied to a woman's grandson. Similarly, a reciprocal stem embraces grandfather and a man's grandson.⁷

Among the Sudanese negroes a great diversity obtains. The Timne terminology is lineal, the words for aunt and uncle being generic and distinct from the parent terms, while cousins in a lump

⁷ Ph. Paulitschke, *Ethnographie Nordost-Afrikas*, 1893, I, 188. M. Merker, *Die Masai*, 1904, p. 41.

are separated from siblings. Some of the languages display an amazing paucity of primary stems, lacking even distinct vocabularies for siblings. Thus, in Ewe "brother" is designated by the descriptive compound "mother's-child-male," and the Edo construct descriptive compounds for "brother" according to whether he is fellow-child through the father or the mother. However, the bifurcate merging principle is by no means eliminated since even in Edo the paternal uncle is frequently classed with the father in address. Nor are typical systems on the bifurcate merging plan lacking. The Susu nomenclature conforms to the Iroquois standard, and this essentially holds for the Ashanti also. Here, however, cross-cousin marriage in some measure has affected classification and the rather extensive use of reciprocal terms partly breaks down the barriers between generations. Thus, *ase* means spouse's parent or child's spouse; *nana* is applied to the grandparent and his sibling or to the grandchild and the sibling's grandchild. Some relatives may be designated descriptively, but this does not interfere with the "classificatory" use of the phrase. For example, the father's brother's child is called either "brother" or "father's child" without any individualization of meaning in either case.¹

Finally, the Lango terminology is of the bifurcate merging type, the partial use of the descriptive technique being once more consistent with "classificatory" meanings. A noteworthy feature is the anomalous designation of cousins. The maternal uncle's son and daughter are designated by descriptive compounds; a distinct stem, with varying vocalic sex-prefix (*okeo*, *akeo*), is applied to the paternal aunt's children; another stem, similarly varied, denotes the mother's sister's son and daughter; while the father's brother's children are treated as siblings. Thus, neither the two kinds of cross-cousins nor the two kinds of parallel cousins are grouped together. The classification of the father's sister's children with the sister's children exhibits an element of the Omaha variety, while other deviations from the generation principle can be derived from rules of widow-inheritance. The occasional designation of a father's sister's son as father is contingent on inheritance of a maternal uncle's widow, making her children the heir's step-children. The Lango nomenclature has been partly shaped by loans from Hamitic neighbours, which have been engrafted on the old Nilotic nomenclature.²

INDONESIA AND OCEANIA

Morgan based his "Malayan" type on Polynesian terminologies. For the Malay branch of the Malayo-Polynesian family he had a single incomplete report from Borneo, which seemed, however, to conform to the Hawaiian norm. There is still great dearth of material for this area. In the Philippines, bifurcation is generally lacking and approximation to the generation system frequently results. But even there the Tinguian, Professor Fay-Cooper Cole states, distinguish uncles and aunts from parents, *i.e.*, fall into the lineal category. This is at least partly true of some "Pagan" systems from Borneo, where aunt and mother are indeed merged, but where the father is distinguished from uncles generally. The importance some Malaysians attach to status is probably significant; where a parent is addressed teknonymously and a grandfather receives an appropriate title, people are on the high-road to stratifying society in terms of generation. However, the Mentawai islanders, representative of archaic Malayan culture, radically differ from the Polynesians in not using personal names in address. They exhibit conflicting tendencies toward a generation, a bifurcate merging, and a bifurcate collateral system: while "ina" is the term of address for mother and father's sister alike, the latter has a separate term in non-vocative use; the maternal uncle is distinguished from the paternal, and the latter is distinguished from the father except vocatively.³

For most of Oceania Rivers has given a convenient summary. Broadly, the Melanesians refrain from using personal names whenever there is a suitable term of relationship, while the Polynesians use personal names even for the closest relatives.

Of the Papuans, the Bânaro, settled on a tributary of the Augusta River, have been accurately described. The differentiation of the maternal uncle suggests a bifurcate merging system, but in other respects they have developed on generation lines, though anomalous matrimonial customs colour the terminology. An interesting distinction is drawn between a paternal aunt who has and one who has not been exchanged for the speaker's mother: the former is called "mother," the latter "maternal uncle's wife." In the contemporary generation, siblings are distinguished according to seniority, cousins are treated as siblings, but are designated in accordance with the relative seniority of the connecting parents. This feature is shared by such Melanesians of New Guinea as the Jabim. These tribes fall into the bifurcate merging category. Reciprocal terms occur for grandfather and grandson, maternal uncle and sister's son, parent-in-law and child-in-law.⁴

HISTORICAL AND SOCIOLOGICAL INTERPRETATIONS

Morgan inaugurated both historical and sociological interpretations of the facts he scheduled. Starting from the axioms that kinship classifications were "independent of the mutations of language" (p. 506) and that they could not be diffused except if the phonetic symbols themselves were borrowed, he accepted the similarity of systems as proof of racial identity. He thus inferred the unity of the Dravidians and the American Indians, and that of the Zulu and the Hawaiians (p. 466). Apart from the questionableness of the premises this argument would lead to the absurd conclusion that the Eastern North American Indians stood racially much closer to the Melanesians and various Africans than to their congeners of the Basin area. However, by his collation of specific resemblances, Morgan paved the way for sound historical conclusions. For example, he recognized the likeness of certain Central Algonkian and southern Siouan systems (p. 179)—a fact now interpreted as the result of diffusion. Diffusion evidently is the only possible explanation of the concentration west of the Rockies of such features as the discrimination between paternal and maternal grandparents.

Sociologically, Morgan viewed his nomenclatures as indices of family life. The "Malayan" as the simplest was considered the earliest; and since it failed to distinguish the mother's brother from the father, Morgan concluded that the two were identical, *i.e.*, that a man had access to his own sister when the system originated. The introduction of a term for maternal uncle was said to result from the prohibition of such unions when the Turanian-Ganwanian system arose. Finally, the "descriptive" terminology, failing to merge any collateral relatives with the direct line of descent, was correlated with the rise of property rights and the parents' insistence on transmitting them only to direct descendants (p. 492f.). The scheme thus forms part of an evolutionary theory explaining the gradual rise of our civilized family out of more or less promiscuous beginnings.

These interpretations are now recognized as basically wrong. Morgan was not warranted in assuming that the Polynesian term translated "father" implied procreation: the facts simply reveal a common status term for all kindred of one generation. Simplicity here, as in many other linguistic phenomena, is a late development, not a badge of antiquity. Three independent investigators, Sternberg in Siberia, Rivers in Oceania, Lowie in North America, have been able to show recent transformations of bifurcate merging nomenclatures in the direction of generation systems.

Morgan's extravagance led Kroeber to reject sociological interpretations almost *in toto*. In reply to criticism by Rivers, he has long since receded from this position, specifically admitting the correlation of certain terminological features with cross-cousin terminology. The issue was thus reduced to a difference in philosophical attitude toward cultural phenomena. Rivers championed a rigid determinism, contending that "not only has the

⁴R. Thurnwald, *Die Gemeinde der Bânaro*, 1921, 60 sq. C. G. Seligman, *The Melanesians of British New Guinea*, 1910, 66, 481, 707.

general character of systems of relationship been strictly determined by social conditions, but every detail of these systems has also been so determined." On the other hand, Kroeber insisted that "the infinitely variable play of the variable factors forbids any true determinations of causality of a sweeping character."

Kroeber was unquestionably right in rejecting Rivers' extreme claim, and in maintaining that since kinship terms were linguistic phenomena, they were subject to alterations of a linguistic character, e.g., extensions in meaning, independently of social conditions. However, he did not sufficiently consider that language represents reality and that in so far as it related to social phenomena it is likely to mirror them, even though imperfectly. The empirical facts of distribution indicate that the correlation between social custom and nomenclature is indeed far from perfect, but fairly high.

First of all, there is an undeniable tendency to designate by separate terms relatives with distinctive social functions. It is not sheer accident that Polynesians generally lack a term for the maternal uncle, but that a term appears with the avunculate. Furthermore, the same term applied to different individuals is an index of their sharing the same duties and claims, as Radcliffe-Brown has pointed out for Australia.

Secondly, how are we to interpret the data of geographical distribution? Rivers found that neighboring Oceanians often differed more widely in their kinship systems than remote tribes. A survey of the world establishes this fact on a broader basis. Morgan's solution of resemblances in Dravidian and Iroquois nomenclature is impossible, but he put his finger on a real problem. When the Omaha of Nebraska resemble the Californian Miwok far more than their fellow-Siouans; when specific Omaha features crop up in some Assamese tribes and again on the upper Nile, the fact naturally arouses curiosity and calls for explanation. If the same social factors uniformly accompany the terminological resemblance, a genuine correlation is established. Thus, the grouping of the mother's brother's son with the maternal uncle in the tribes cited is linked with paternal descent, while the classification of the father's sister's son with the father, and of the father's sister's daughter with the paternal aunt generally accompanies maternal descent. We are not dealing with a simple causal nexus, for there are matrilineal tribes like the Seneca and patrilineal tribes like the Ojibwa who do not override the generation principle in this fashion. But a functional relationship remains. It is conceivable that the Omaha and Crow varieties of the bifurcate merging type depend on additional factors that may some time be discovered.

That, without prejudice to other functional relations, a high correlation obtains between a clan organization and the bifurcate merging system, seems certain. Clanless tribes like the Andamanese, Chukchee, Basin Shoshoneans, Hawaiians, have no terminologies of this type; characteristic clan organizations are almost uniformly coupled with them. Tylor's generalization, corroborated by Rivers and Lowie for Oceania and North America, respectively, seems to hold.² Yet it is possible to derive the terminology from the joint effect of the levirate and the sororate, institutions probably quite as widely distributed as the clan organization. True, they do not explain why in the common Iroquois variety of the type parallel cousins of the same sex are grouped together, while cross-cousins of the same sex are segregated under a common term of their own. Tylor's idea that the moiety represents the primeval clan does explain this; but large sections of the world with the bifurcate merging nomenclature—notably Africa—lack moieties.

In the present state of our knowledge, then, we may say that while social correlations of terminological features are undeniable,

Rivers, *Kinship and Social Organization*. Lowie, "Exogamy and the Classificatory System of Relationships," *Am. Anth.*, 1915, 223-239.

we are not usually in a position to determine a simple cause-effect relationship. There are often alternative explanations: the mother's brother may be identified with the father's sister's husband because of cross-cousin marriage or because they both belong to the same exogamous moiety or because two households arrange to marry off their respective daughters to the boys in the other household (Rivers). The safe rule is to reject any social determinant of a nomenclatorial trait unless it is reported as extant in the tribe or at least in the general area in question.

Other phases of the problem must be considered. An institution may be overshadowed by coexisting institutions or it may not yet have had time to assert itself terminologically. The Miwok, e.g., practise cross-cousin marriage but their terminology shows a far deeper impress of rival forms of marriage. It seems a fair conclusion that the latter are of greater antiquity.¹

Diffusion presents a further complication. While harmony between the nomenclature and the social structure is frequent, there are discrepancies that can be most readily interpreted by borrowing. To exemplify, there are tribes with a bifurcate merging terminology that lack clans, but their location suggests that they have borrowed a neighbor's nomenclature. It would be dangerous to infer that they had at one time been organized into clans, unless extraneous data so suggest.

Finally, there are the linguistic factors stressed by Kroeber. When nearly all Siouan languages have a separate term for paternal aunt, the lack of such a word (in address only) among the Crow must be interpreted as a late development; and the use of the "mother" word appears as a characteristic sample of linguistic extension,—the same phenomenon as when English uses "wife" as a special term of affinity while the cognate German *Weib* applies to woman generically. The reality of such phenomena militates against any attempt to reduce the whole of kinship terminology to social causes. There will always be residual phenomena resisting interpretation on any but linguistic lines. This means that they are in a sense unique facts that can be understood after they have been observed but that could not be deduced from general principles.²

These cautions limit but do not destroy the sociological significance of relationship terminologies. When all allowances are made for disturbing factors, a host of correlations remain between kinship features and sociological factors. When more intensive studies of large linguistic families shall be available, it will be possible to balance with greater nicety the relative importance of sociological and other factors as determinants. (R. H. Lo.)

RELATIVITY. The progress of natural science in the first quarter of the present century was especially noteworthy through the appearance of the doctrine of relativity, and its almost immediate acceptance by the scientific world in general. The need for some such theory had long been felt and was becoming continually more urgent. As far back as 1837 Michelson and Morley, experimenting for quite another purpose, had obtained results which obstinately refused to fit into 19th-century conceptions of the general nature of the universe. Experiments in other directions soon indicated that the difficulties thus revealed were not isolated difficulties confined to one special corner of science, but extended throughout a large part of electrical and optical science. Theoretical discussions by Lorentz, Larmor and others drew attention to the serious nature and extent of the difficulties which had arisen, and pointed, although somewhat vaguely, to the direction in which a solution was likely to be found.

The first intimation of the revolution in thought which had now become necessary was given by Henri Poincaré, who, in an address delivered before the International Congress of Arts and Science at St. Louis on Sept. 24, 1904,¹ formulated a "principle of relativity," namely, that the laws of physical phenomena ought to be the same for any two observers, one of whom has a movement of uniform translation relative to the other; so that we can not by any

means discover whether we are or are not partaking in such a movement. After examining the results of observation and experiment in the light of this principle, Poincaré declared that an entirely new type of dynamics was required, characterized by the law that no velocity could exceed that of light. The program thus indicated was carried out in 1905¹ by Albert Einstein, then professor of theoretical physics in the University of Berne.

At this time gravitation held obstinately aloof from all other physical phenomena; an ether had been devised which explained optical and electrical phenomena with fair success, but it refused to find room for the phenomenon of gravitation. In 1915 Einstein published further papers which showed that gravitation admitted of a very simple explanation in terms of the new ideas as to the nature of space and time. The gravitation which was explained in this way was, however, just a shade different from the gravitation of Sir Isaac Newton. When it was realized that the gravitation of nature was also just a shade different from that of Newton, and it was further discovered that nature ranged herself completely with Einstein in this matter, then the acceptance of Einstein's theory was universal and complete.

While gravitation fitted quite naturally into the new scheme of nature demanded by the theory of relativity, it was found to be less easy to fit in the general phenomena of electromagnetism. The years after 1918 saw a great deal of discussion as to the way in which these must be joined on to Einstein's general theory of relativity and, as we shall see below, the issue is still in doubt.

General Nature of the Principle.—Science advances in two ways, by the discovery of new facts, and by the discovery of mechanisms or systems which account for the facts already known. The outstanding landmarks in the progress of science have all been of the second kind. Such, for instance, was the Copernican system of astronomy, which explained the already known motions of the planets; such was the Newtonian mechanism (the force of gravitation) which explained the elliptic orbits of the planets and the earth's pull on terrestrial bodies; such was the Darwinian mechanism of natural selection, which explained the survival of some species and the extinction of others. Such also is the theory of relativity.

The scientist's desire to discover mechanisms or systems arises no doubt primarily from the constitution of the human mind; our intellects, unsatisfied with a mere accumulation of facts, impel us ever to search for the causes underlying the facts: *Veri scire est per causas scire*. But to the working scientist the discovery of a mechanism has an additional and more practical value. When he has found a mechanism which will account for certain laws, he can proceed to examine the complete set of laws which the mechanism demands. If his mechanism corresponds with sufficient closeness to reality he may in this way be led to the discovery of new natural laws. On the other hand, the new laws deduced from the supposed mechanism may be false. If the falsity of the new laws is not at once revealed science may for a time be led into wrong paths. When more accurate experimenting or observation discloses that the new laws are not true a recasting of ideas becomes necessary, and the branch of science concerned may experience a time of revolution followed by a period of rapid growth.

An obvious illustration of these general statements is provided by the history of astronomy. The laws of the motions of the planets, as observed from the earth, were tolerably well-known to the Greeks. They had also evolved an explanatory mechanism starting from the premise, which seemed to them to be necessary on metaphysical grounds, that the paths of the planets must necessarily be circles. The earth was the centre of the universe and round this revolved spheres to which the planets were attached. The retrograde motion of the outer planets was explained by supposing that they were attached to secondary spheres revolving about points on the primary spheres which in turn revolved about the earth. This mechanism of cycles and epicycles as an explanation of planetary motion held the field for 18 centuries. Finally the observations of Tycho Brahe provided a test which

revealed the falsity of the whole structure. The position of Mars was found to differ from that required by the mechanism of epicycles by an amount as great as 8 min. of arc. "Out of these eight minutes," said Johann Kepler, "we will construct a new theory that will explain the motions of all the planets."

The history of the succeeding century of astronomy need not be recapitulated here. The earth yielded its place as the centre of the universe, and the structure of cycles and epicycles crumbled away. The laws of planetary motion were determined with a precision which for the time appeared to be final. The mechanism underlying these laws was supposed to be a "force" of gravitation. This force was supposed to act between every pair of particles in the universe, its intensity varying directly as the product of the masses of the particles and inversely as the square of the distance separating them—the famous law of Newton.

In science, history repeats itself and, in recent years, the theory of relativity has provided a further instance of the general processes we have been considering. Under the Newtonian mechanism every planet would describe a perfect ellipse about the sun as focus, and these elliptic orbits would repeat themselves indefinitely except in so far as they were disturbed by the gravitational forces arising from the other planets. But, after allowing for these disturbing influences, Urbain Leverrier found that the orbit of the planet Mercury was wobbling in its own plane at the rate of 43 sec. a century. Various attempts have been made to reconcile this observed motion with the Newtonian mechanism. The gravitational forces arising from the known planets were demonstrably unable to produce the motion in question, but it was possible that Mercury's orbit was being disturbed by matter so far unknown.

Investigations were made as to the disturbance to be expected from various hypothetical gravitating masses—a planet or a ring of planets between Mercury and the sun, a ring of planets outside the orbit of Mercury, a belt of matter extended in a flattened disk in a plane through the sun's centre, an oblateness greater than that suggested by the shape of the sun's surface, in the arrangement of the internal layers of the sun's mass. In every case the mass required to produce the observed disturbance in the motion of Mercury would have also produced disturbances not observed in the motions of the other planets. The solution of the problem came only with the theory of relativity. Just as Tycho's 8 min. of arc, in the hands of Kepler and Newton, revolutionized mediaeval conceptions of the mechanism of the universe, so Leverrier's 43 sec. of arc, in the hands of Einstein, has revolutionized our 19th-century conceptions, not only of purely astronomical mechanism, but also of the nature of time and space and of the fundamental ideas of science. The history of this revolution is in effect the history of the theory of relativity. It falls naturally into three chapters, a first narrating the building of the earlier physical theory of relativity, a second dealing with the extension of that theory to gravitation, and a third, which is still in process of being written, attempting to include electromagnetism in the physical system presented by the existing theory of relativity.

THE PHYSICAL THEORY OF RELATIVITY

The earliest successful attempt to formulate the laws governing the general motion of matter is found in Newton's laws. The first law states that:—

Every body perseveres in its state of rest or of uniform motion in a right line unless it is compelled to change that state by forces impressed thereon.

In this law no distinction is made between rest and uniform motion in a straight line, and the same is true of the remaining laws. Hence follows the property to which Newton draws explicit attention in his fifth corollary to the laws of motion:—

The motions of bodies included in a given space are the same among themselves, whether that space is at rest, or moves uniformly forwards in a right line without any circular motion.

As a concrete application of his principle, Newton instances "the experiment of a ship, where all motions happen after the same manner whether the ship is at rest or is carried uniformly forward in a right line." Just as a passenger on a ship in a still

¹Einstein's paper, *Ann. d. Phys.* 17:841 (1905) is dated June 30, 1905.

sea could not determine, from the behaviour of bodies inside the ship, whether the ship was at rest or moving uniformly forward, so we cannot determine from the behaviour of bodies on our earth whether the earth is at rest or not. We believe the earth to be moving round the sun with a speed of about 30 km. a second, so that there can be no question of the earth being permanently at rest, but we are unable to determine whether it is at rest at any specified point of its orbit, or, in the probable event of its not being at rest, what its absolute velocity may be. There is no more reason for thinking the sun, than the earth, to be at rest. Newton wrote as follows:—

"It is possible that in the remote regions of the fixed stars, or perhaps far beyond them, there may be some body absolutely at rest, but impossible to know, from the positions of bodies to one another in our regions, whether any of these do keep the same position to that remote body. It follows that absolute rest cannot be determined from the position of bodies in our regions."

The above quotations are all from the first book of the *Principia Mathematica*. Previous to them all Newton writes: "I have no regard in this place to a medium, if any such there is, that freely pervades the interspaces between the parts of bodies." The two centuries which elapsed after the publication of the *Principia* witnessed a steady growth of the belief in the reality of such an all-pervading medium. It was called the ether, or aether, and by the end of these two centuries (1887) it was almost universally believed that light and all electromagnetic phenomena were evidence of actions taking place in this ether. Light from the most distant stars was supposed to be transmitted to us in the form of wave motions in the ether, and we could see the stars only because the sea of ether between us and these stars was unbroken. It had been proved that if this sea of ether existed it must be at rest, for the alternative hypothesis that the ether was dragged about by ponderable bodies in their motions had been shown to be incompatible with the observed phenomenon of astronomical aberration and other facts of nature. On this view it was no longer necessary to go to Newton's "remote regions of the fixed stars, or perhaps far beyond them," to find absolute rest. A standard of absolute rest was provided by the ether which filled our laboratories and pervaded all bodies. Owing to our motion it would appear to be rushing past us, although without encountering any hindrance—"like the wind through a grove of trees," to borrow the simile of Thomas Young. The determination of the absolute velocity of the earth was reduced to the problem of measuring the velocity of an ether current flowing past us and through us.

In this same year (1887) the first experimental determination of this velocity was attempted by the Chicago physicist Michelson. The velocity of light was known to be, in round numbers, 300,000 km. a second, a velocity which was interpreted as representing the rate of progress of wave motion through the ether. If the earth were moving through the ether with a velocity of 1,000 km. a second, the velocity of light relative to a terrestrial observer ought to be only 299,000 km. a second when the light was sent in exactly

FIG. 1.—DIAGRAM OF MICHELSON'S APPARATUS Designed to ascertain the earth's velocity through the ether

the direction of the earth's motion through the ether, but would be 301,000 km. a second if the light was sent in the opposite direction. In more general terms, if the earth were moving through the ether, the velocity of light, as measured by a terrestrial observer, would depend on the direction of the light, and the extent of this dependence would give a measure of the earth's velocity. The velocity of light along a single straight course does not permit of direct experimental determination, but the same property of dependence on direction ought to be true, although to a less extent, of the average to-and-fro velocity of a beam of light sent along any path and then reflected back along the same path.

It was through this property that Michelson attempted to measure the earth's velocity through the ether. The apparatus was simple in principle. A circular table ABCD (see fig. 1) was arranged so as to be capable of slow rotation about its centre O.

Light sent along CO was divided up at O into two beams which were made to travel along perpendicular radii OA, OB. The arms OA, OB were made as equal as possible and mirrors were placed at A and B to reflect the beams of light back to O. An extremely sensitive optical method made it possible to detect even a very slight difference in the times of the total paths of the two beams from O back to O. There would in any case be a difference owing to the necessarily imperfect equalization of the lengths of the arms OA, OB, but if the earth is moving through the ether in some direction OP, and if the table is made to rotate slowly about O, then this difference ought itself to vary on account of the earth's motion through the ether. Michelson, and afterwards Michelson and Morley in collaboration, attempted to estimate the amount of this variation. No variation whatsoever could be detected, although their final apparatus was so sensitive that the variation produced by a velocity through the ether of even 1 km. a second ought to have shown itself quite clearly.

Thus to the question "What is our velocity through the ether?" nature appeared to give the answer "None." It was never suggested that this answer should be accepted as final; this would have brought us back to a geocentric universe. Clearly either the question had been wrongly framed or the answer wrongly interpreted. It was pointed out in 1893 by George F. FitzGerald, and again independently, in 1895, by Lorentz, that the *null* result of the Michelson-Morley experiment could be explained if it could be supposed that motion through the ether altered the linear dimensions of bodies. They both showed that the experiment would invariably and of necessity give a *null* result if every body moving through the ether with a velocity u was contracted in the direction

of its motion in the ratio $\sqrt{1 - \frac{u^2}{c^2}}$, c being the velocity of light.

The supposition that such a contraction occurred was not only permissible—it was almost demanded by electrical theory. Indeed, Lorentz had already shown that if matter were a purely electrical structure, the constituent parts would of necessity readjust their relative positions when set in motion through the ether and the final position of equilibrium would be one showing precisely the contraction just mentioned.

On this view, there was no *prima facie* necessity to abandon the attempt to measure the earth's velocity through the ether. The answer to the problem had merely been pushed one stage farther back, and it now became necessary only to measure the shrinkage of matter produced by motion. It was obvious from the first that no direct material measurement could disclose the amount of this shrinkage, since any measuring rod would shrink in exactly the same ratio as the length to be measured; but optical and electrical methods appeared to be available. Experiments to this end were devised and performed by Lord Rayleigh, De Witt Bruce, Frederick T. Trouton and H. R. Noble, Trouton and Alex O. Rankine and others. In every case a *null* result was obtained. It appeared then that if the earth moved through the ether this motion was concealed by a universal shrinkage of matter, and this shrinkage was in turn concealed by some other agency or agencies.

At this time the word "conspiracy" found its way into the technical language of science. There was supposed to be a conspiracy on the part of the various agencies of nature to prevent man from measuring his velocity of motion in space. If this motion produced a direct effect x on any phenomenon, the other agencies of nature seemed to be in league to produce a countervailing effect $-x$. A long train of experiments had not revealed, as was intended, our velocity through the ether; they had merely created a conviction that it was beyond the power of man to measure this velocity. The conspiracy, if such there was, appeared to have been perfectly organized.

A perfectly organized conspiracy of this kind differs only in name from a law of nature. The inventor who tries to devise a perpetual-motion machine may come to the conclusion that the forces of nature have joined in a conspiracy to prevent his machine from working, but wider knowledge shows that he is in conflict not with a conspiracy, but with a law of nature—the conservation of energy. In 1904 Poincaré crystallizing an idea which

must have been vaguely present in many minds, propounded the hypothesis that the apparent conspiracy might be in effect a law of nature. He suggested that there might be a true law to the effect that "it is of necessity impossible to determine absolute motion by any experiment whatever." This hypothetical law may again be put in the equivalent form: "The phenomena of nature will be the same to two observers who move with any uniform velocity whatever relative to one another." As we have seen, Poincaré called this the principle of relativity. It belongs to the class of statements which have been named by Edmund T. Whittaker postulates of impotence; these are statements which assert the impossibility of achieving something, even though there may be an infinite number of ways of trying to achieve it. The second law of thermodynamics, the principle of uncertainty in quantum mechanics and the principle of the indistinguishability of electrons are of this nature.

The hypothesis in itself was not of a sensational character. Indeed, from the quotations which have already been given from Newton's works, it appears probable that Newton himself would have accepted the hypothesis without hesitation: he might even have regarded it as superfluous. The true significance of the hypothesis can only be understood by a reference to the scientific history of the two centuries which had elapsed since Newton. The Newtonian view that absolute rest was to be found only "in the remote regions of the fixed stars, or perhaps far beyond them," had given place to a belief that absolute rest was to be found all around us in an ether which permeated all bodies. What was striking about the hypothesis was its implication—either that we could not measure the velocity relative to ourselves of a medium which surrounded us on all sides, or else that no such medium existed.

The hypothesis demanded detailed and exhaustive examination. It was for the mathematician to test whether it was in opposition to known and established laws of physics and to this task Einstein, Lorentz and others set themselves. If the hypothesis proved to be in opposition to a single firmly established law, then of course it must be abandoned. It was unlikely that such an event would occur among the well-established laws, for if it did, the phenomena governed by that law would enable direct measurement to be made of the earth's velocity through the ether, a measurement which had so far eluded all attempts of experimenters. It was among the more obscure and less well-established laws, if anywhere, that discrepancies were to be looked for.

It is impossible here to give a complete account of the many tests to which the relativity hypothesis has been subjected. The result of all can be summed up in one concise and quite general statement:—Wherever the hypothesis of relativity has appeared to be in conflict with known or suspected natural laws, further experiment, where possible, has without a single exception shown the laws to be erroneous, and has moreover shown the alternative laws suggested by the hypothesis of relativity to be accurate. It is only in somewhat exceptional cases that the hypothesis of relativity suffices of itself to determine fully the form of a natural law; these cases constitute the most striking triumphs of the theory. As instances may be mentioned the determination of the law connecting the mass of an electron with its velocity; of the law expressing the velocity of light through a transparent medium in motion (Armand Fizeau's water-tube experiment); and of the formulae for the magnetic forces on moving dielectric media (experiments of A. Eichenwald and H. A. Wilson).¹

Before leaving this general statement, particular mention must be made of one special case. A natural law which, at an early stage, was seen to be in conflict with the hypothesis of relativity was Newton's famous law of gravitation—namely, that every particle of matter attracts every other particle with a force proportional to the product of the two masses, and to the inverse square of their distance apart. Either, then, Newton's great law had to be abandoned or else the hypothesis of relativity had to be discarded, in which case it would immediately become possible, in

theory at least, to determine the earth's velocity through space by gravitational means. It is the choice between these two alternatives that has led to the most surprising developments of the theory of relativity; and to these we shall return later.

The hypothesis of relativity, as has already been explained in this section, postulates that the phenomena of nature will be the same to two trained observers moving relative to one another with any uniform velocity whatever. The hypothesis has been so amply tested as regards all optical and electromagnetic phenomena that no doubt is felt, or can rationally be felt, as to its truth with respect to these phenomena. The hypothesis can be examined and developed in two opposite directions. We may, on the one hand, proceed from the general hypothesis to the detailed laws implied in it; this has already been done with completely satisfactory results as regards confirmation of the hypothesis. Or regarding the hypothesis of relativity as being itself a detailed law, we may attempt to generalize upward to something still wider. It is this possibility which must for the moment claim our attention.

In 1905 Einstein examined in full the consequences of the hypothesis that one simple optical phenomenon—namely, the transmission of a ray of light in free space—was, in accordance with the hypothesis of relativity, independent of the velocity of the observer. If an ether existed, and provided a fixed framework of reference, then light set free at any instant would obviously travel with a velocity which would appear to an observer at rest in this ether to be the same in all directions, and the wave front at any instant would be a sphere having the observer as centre. On the hypothesis of relativity the phenomenon of light transmission must remain unaffected by the motion of the observer, so that the light must appear, to a moving observer also, to travel with a uniform velocity in all directions, and thus to the moving observer also the wave front must appear to be a sphere of which he is the centre. It is, however, quite obvious that the same spherical wave front cannot appear, to each of two observers who have moved some distance apart, to be centred round himself, unless the use either of the common conceptions of science or of the ordinary words of language is greatly changed. In fig. 2 it is not possible, in ordinary language, that both O and P should at the same instant be at the centre of the sphere ABC. The change to which Einstein was forced is one which has an intimate bearing upon our fundamental conceptions of the nature of space and time; this change it will be necessary to explain in some detail.

Suppose that two observatories, say Greenwich and Paris, wish to synchronize their clocks, with a view to, let us say, an exact determination of their longitude difference. Paris will send out a wireless signal at exact midnight as shown by the Paris clock, and Greenwich will note the time shown by the Greenwich clock at the instant of receipt of the signal. Greenwich will not, however, adjust its clock so as to show exact midnight when the signal is received; a correction of about .002 sec. must be made to allow for the time occupied by the signal in traversing the distance from Paris to Greenwich. To turn to mathematical symbols, if t_0 is the time at which a signal is sent out from one station, the time of

receipt at a second station is taken to be $t_0 + \frac{x}{c}$, where x is its distance apart, and c is the velocity of light. This represents the ordinary practice of astronomers, but it is clear that if the earth is travelling through a fixed ether with a velocity u in the direction of the line joining the two observatories, the velocity of transmission of the signal relative to the two observatories will not be c but $c+u$, and the time of receipt at the second station will be $t_0 + \frac{x}{c+u}$.

Thus it appears that it is impossible to synchronize two clocks unless we know the value of u , and that the ordinary practice of astronomers will not, as they expect, synchronize their clocks, but set them at an interval apart equal to

$$x \left(\frac{1}{c} - \frac{1}{c+u} \right)$$

which may, to an approximation, be put equal to $\frac{ux}{c^2}$.

According to the hypothesis of relativity, it is impossible ever to determine the value of u , and so it is impossible ever truly to

¹For references to the original papers dealing with these and other tests of the hypothesis of relativity see E. Cunningham, *The Principle of Relativity*, or J. H. Jeans, *Mathematical Theory of Electricity and Magnetism* (4th or 5th ed.).

synchronize two clocks. Moreover, according to this hypothesis, the phenomena of nature go on just the same whatever the value of u , so that the want of synchrony cannot in any way show itself—in fact, if it did, it would immediately become possible to measure the effect and so arrange for true synchrony.

As the earth moves in its orbit, the value of u changes, so that its value in the spring, for instance, will be different from its value in the autumn. One pair of astronomers may attempt to synchronize a pair of clocks in the spring, but their synchronization will appear faulty to a second pair who repeat the determination in the autumn. There will, so to speak, be one synchrony for the spring and another for the autumn, and neither pair of astronomers will be able to claim that their results are more accurate than those of their colleagues. Different conceptions of synchrony will correspond to different velocities of translation.

These elementary considerations bring us to the heart of the problem which we illustrated diagrammatically in fig. 2. The observer at O in the diagram will have one conception of simultaneity, while the second observer who moves from O to P, will, on account of his different velocity, have a different conception of simultaneity. The instants at which the wave front of the light signal from O reaches the various points A, B, C in the diagram will be deemed to be simultaneous by the observer who remains at O, but the observer who moves from O to P will quite unconsciously have different ideas as to simultaneity. At instants which he regards as simultaneous the wave front will have some form other than that of the sphere ABC surrounding O. If the hypothesis of relativity is to be true in its application to the transmission of light signals, this wave front must be a sphere having P as its centre. Einstein examined mathematically the conditions that this should be possible. A precise statement of his conclusions can only be given in mathematical language.

The observer who remains at O in fig. 2 may be supposed to make exact observations and to record these observations in mathematical terms. To fix the positions of points in space he will map out a "frame of reference" consisting of three orthogonal axes, and use Cartesian co-ordinates x, y, z , to specify the projections along these axes of the radius from the origin to any given point. He will also use a time co-ordinate t which may be supposed to specify the time which has elapsed since a given instant, as measured by a clock in his possession. Any observations he may make on the transmission of light signals can be recorded in the form of equations between the four co-ordinates x, y, z, t . For instance the circumstance that light travels from the origin with the same velocity c in all directions, will be expressed by the equation (of the wave front):—

$$x^2 + y^2 + z^2 - c^2 t^2 = 0 \quad \dots \dots (1)$$

The second observer who moves from O to P will also construct a frame of reference, and we can simplify the problem by supposing that his axes are parallel to those already selected by the first observer. His co-ordinates, to distinguish them from those used by the first observer, may be denoted by the accented letters x', y', z', t' . If his observations also are to show light always to travel with the same velocity c in all directions, the equation of the wave front, as observed by him, must be:—

$$x'^2 + y'^2 + z'^2 - c'^2 t'^2 = 0 \quad \dots \dots (2)$$

A 19th-century mathematician would have insisted that x, y, z, t must necessarily be connected with x', y', z', t' by the simple relations:—

$$\left. \begin{aligned} x' &= x - ut \\ y' &= y \\ z' &= z \\ t' &= t \end{aligned} \right\} \dots \dots (A)$$

Indeed, he would have been unable to imagine that there should be any other relation connecting these quantities. It is, however, obvious that if these relations hold, then equation (1) cannot trans-

form into equation (2). Einstein showed that equation (1) will transform into equation (2) provided the co-ordinates x, y, z, t of the first observer are connected with the co-ordinates x', y', z', t' of the second observer by the equations:—

$$\left. \begin{aligned} x' &= \beta (x - ut) \\ y' &= y \\ z' &= z \\ t' &= \beta \left(t - \frac{ux}{c^2} \right) \end{aligned} \right\} \dots \dots (B)$$

where β stands for $\left(1 - \frac{u^2}{c^2}\right)^{-\frac{1}{2}}$.

To form some idea of the physical meaning of these equations, let us consider the simple case in which the first observer is at rest in the ether while the second moves through the ether with velocity u . The points of difference between equations (B) and (A) then admit of simple explanation. The factor β in the first of equations (B) is simply, according to the suggestion of FitzGerald and Lorentz already mentioned, the factor according to which all lengths parallel to the axis of x must be adjusted on account of motion through the ether with velocity u . The moving observer must correct his lengths by this factor, and he must correct his times by the same factor in order that the velocity of propagation of light along the axis of x may still have the same velocity c ; this explains the presence of the multiplier β in the last of equations (B). The one remaining difference between the two sets of equations, namely, the replacement of t in (A) by $t - \frac{ux}{c^2}$ in (B), represents exactly the want of synchrony which, as we have already seen, is to be expected in the observations of two observers whose velocity differs by a velocity u .

Although the equations admit of simple illustration by considering the case in which one observer is at rest in a supposed ether, it will be understood that the equations are more general than the illustration. They are in no way concerned with the possibility of an observer being at rest in an ether, or indeed the existence of an ether at all. Their general interpretation is this: If one observer O, having any motion whatever, finds, as a matter of observation, that light for him travels uniformly in all directions with a constant velocity c , then a second observer P, moving relative to O with a constant velocity u along the axis of x , will find, as a matter of observation, that light, for him also, travels uniformly in all directions with the same constant velocity c , provided he uses, for his observations, co-ordinates which are connected with the co-ordinates of O by equations (B).

This is the meaning that was attached to the equations by Einstein in 1905, but the equations had been familiar to mathematicians before this date. They had in fact been applied to the equations of vibratory motions in 1887 by Woldemar Voigt, and had been rediscovered by Lorentz in 1895 as expressing the condition that all electromagnetic phenomena, including of course the propagation of light, should be the same for an observer moving through the ether with velocity u as for an observer at rest in the ether. For this reason the transformation of co-ordinates specified by these equations is universally spoken of as a "Lorentz transformation." What Einstein introduced in 1905 was not a new system of equations but a new interpretation of old equations. The two observers who used the co-ordinates x, y, z, t and x', y', z', t' had been regarded by Lorentz as being one at rest in an ether and one in motion with a velocity u ; for Einstein they were observers moving with any velocities whatever subject to their relative velocity being u . Lorentz had regarded t as the true time and t' as an artificial time. If the observer could be persuaded to measure time in this artificial way, setting his clocks wrong to begin with and then making them gain or lose permanently, the effect of his supposed artificiality would just counterbalance the effects of his motion through the ether. With Einstein came the conception that both times, t and t' , had precisely equal rights to be regarded as true time. The measure of time is precisely that which would be

adopted naturally by any set of observers, or race of men, who disregarded their steady motion through space; their adoption of it would be above criticism if, as Einstein suggested, their motion through space had no influence on material phenomena, and it represents, as we have seen, the usual practice of astronomers in comparing time at different places. From this point of view neither measure of time is more accurate or more logical than the other. There are as many ways of measuring time as there are observers, and all are right.

The investigator who is trying to discover laws of nature will, in general, require to measure both time and space either directly or indirectly. If, to take a simple case, he is studying the motion of a single particle, he will measure out the position of the particle at definite instants as determined by his clock. He may specify the position of the particle at any instant by three measurements in space—for instance, he may say that two seconds after his particle started it was 6 ft. to the E. of the point from which it started, 9 ft. to the N. and 12 ft. vertically upward. The mathematician would express this by taking axes x, y, z to the E., to the N. and vertically upwards, and saying that at time $t=2$ the particle had co-ordinates $x=6, y=9, z=12$. Or he might, putting his time co-ordinate t on the same footing as the space co-ordinates x, y, z , simply say that $x=6, y=9, z=12, t=2$ represented one position of the particle. A complete set of readings of this type, each consisting of values of four co-ordinates, would give the complete history of the motion of the particle.

Such sets of simultaneous measurements form the common material of investigations in both pure and applied science. For instance, the engineer may measure the extension of a sample of steel corresponding to different loads; the electrician may measure the amount of light given by an electric filament corresponding to different amounts of current passed through it. In each of these cases there are only two quantities to be measured simultaneously, and an investigator can conveniently represent the result of the whole series of his measurements in graphical form; a single reading is represented by a point whose distances from two fixed perpendicular lines represent the quantities measured, and the curve obtained by joining these single points will give all the information contained in the whole set of readings.

We have seen that, in studying the motion of a particle in space, four sets of quantities must be measured, so that the results obtained cannot be plotted graphically on a piece of paper. Their proper representation demands a four-dimensional space, in which x, y, z and t are taken as co-ordinates. The practical importance of such graphical representation is nil, since it is impossible to construct a four-dimensional graph, but its theoretical importance to the theory of relativity is immense. For if the hypothesis of relativity is true, then the four-dimensional graphs of any natural event constructed by all observers, no matter what their relative motions, will be identical. The influence of their motion will be shown only in that the axes of x, y, z and t will be different for different observers, and the relations between these sets of axes will be those given by the foregoing equations (B).

The importance of this conception can hardly be overestimated, and it may be well to consider it further with the help of an illustrative example. Imagine a number of aeroplanes flying over England, and, in order to eliminate one of the three directions in space—the vertical—let us limit them to fly always at the same height, say 1,000 ft. above sea-level. Imagine a number of similar plates of glass prepared, each marked faintly with an outline map of England and with lines of latitude and longitude. Suppose that at 12 hr. o min. G.M.T. a plate is taken and the position of each aeroplane marked by a thick black dot. At 12 hr. 1 min. let a second plate be taken and similarly marked, and let this be done every minute for an hour. The 60 plates so marked will constitute a record of the motion of each aeroplane within this hour. If, now, we place the plates in order, one above the other, on a horizontal table, the mass of glass so formed will present a graphical representation, in three dimensions, of the motions of all the aeroplanes. In this graph the two horizontal co-ordinates represent motions in any two rectangular directions over England, say east and north, while the third co-ordinate—the vertical—represents

time. The individual black dots which represent the positions of any one aeroplane will form a dotted curve, and this curve gives a graphical representation of the motion of the particular aeroplane. Our rectangle of glass contains the history, for one hour, of all the aeroplanes in graphical form.

To represent the motion of particles in the whole world of space a four-dimensional graph is required. The four-dimensional space in which it is constructed may, following the usual terminology, be spoken of as a four-dimensional continuum. The history of any particle in the universe—just as that of any aeroplane flying over England—will be represented by a continuous line in the continuum, and this is called the "world line" of the particle. If the hypothesis of relativity is true, the same continuum and the same world lines will represent the history of the particles of the universe equally well for all observers, the influence of their motions being shown only through their choosing different axes in the continuum for their axes of space and time. Thus the continuum must be thought of as something real and objective, but the choice of axes is subjective and will vary with the observer, the relation between different choices being expressed mathematically by our equations (B), the equations of the Lorentz transformation. An inspection of these equations shows that the sets of axes chosen by different observers have different orientations in the continuum, so that what one observer describes as a pure space interval will appear to another to be a mixture of time and space.

The instant of time and point in space at which any event occurs can be fixed by a single point in the continuum, so that the interval between two events will be represented by a finite line. The events and the interval between them are absolute, but the interval will be split up into time and space in different ways by different observers. The interval between any two events, such as the great fire of London and the outburst on the star Nova Persei, may be measured by one set of observers as so many years and so many millions of miles, but another set of observers may divide the interval quite differently. For instance a terrestrial astronomer may reckon that the outburst on Nova Persei occurred a century before the great fire of London, but an astronomer on the Nova may reckon with equal accuracy that the great fire occurred a century before the outburst on the Nova. A third astronomer may insist that the events were simultaneous. All may be equally right, although none will be right in an absolute sense. At this stage we may notice one respect in which our pile of glass plates failed to represent the true continuum. The mass of glass was stratified into different plates which represent different times for one particular observer. To obtain a section which would represent what an observer in motion relative to this first observer could regard as simultaneous positions of the aeroplanes, we should have to cut the mass of glass on the slant. The continuum is more closely represented by our plates of glass if they are annealed into a solid mass from which all trace of the original stratification is made to disappear. All observers, no matter what their motion, are then equally free to cut a section to represent their individual ideas of simultaneity.

Thus space and time fade into subjective conceptions, just as subjective as right or left hand, front and behind, are in ordinary life. The continuum alone is objective and may be thought of as containing an objective record of the motion of every particle of the universe. The curve in which this record is embodied is spoken of as the world line of the particle in question. To use the words of Hermann Minkowski: "Space in itself and time in itself sink to mere shadows, and only a kind of union of the two retains an independent existence."

GRAVITATION AND RELATIVITY

Since all the phenomena of light and of electromagnetism are believed, on almost incontrovertible evidence, to be in accordance with the hypothesis of relativity, it is necessarily impossible to determine absolute velocity by optical or gravitational means. On the other hand, as we have already mentioned, the Newtonian law of gravitation is readily seen to be inconsistent with the hypothesis of relativity. Three alternatives are open:

(1) The Newtonian law may be true, in which case it must be

possible to determine absolute velocity by gravitational means.

(ii) The Newtonian law may be untrue in its original form, but may become true when amended so as to conform to the relativity hypothesis.

(iii) Neither of the foregoing possibilities may be true.

Alternative (i) was explored by Sir Oliver Lodge, who, assuming the exact truth of the Newtonian law of gravitation, deduced that the observed motion of the perihelion of Mercury could be accounted for if the sun were moving through space with a velocity of about 70 km. a second in a certain direction. This investigation had to be abandoned when Sir Arthur Eddington pointed out that a similar discussion of the motions of the other planets would lead to vastly different values for the sun's velocity. Alternative (ii) was explored by Einstein and others, but was found to lead to a motion of the perihelion of Mercury equal only to one-sixth part of that actually observed.

Alternative (iii) remained with its innumerable possibilities. Einstein commenced his attack on the problem by eliminating all possibilities which did not conform to two general principles. The first of these was the principle of relativity. Inasmuch as all physical phenomena except gravitation were believed to conform to this principle, it was natural to try as a working hypothesis, the effect of assuming gravitation also to conform. The second principle was the so-called principle of equivalence, and this demands a word of explanation.

To our children we explain that an apple falls to the ground because a force of gravitation inherent in the earth's mass impels the apple towards the centre of the earth. Most schoolboys know that this is not quite the whole story; the path of the apple is more accurately determined by supposing the apple to be acted on simultaneously by two forces—a gravitational force of attraction towards the earth's centre and the centrifugal force arising from the earth's rotation. It is only because the earth's rotation is comparatively slow that the conception of an attraction towards the earth's centre gives a tolerably plausible account of the fall of the apple. If the earth rotated at 17 times its present rate objects would not fall, even approximately, towards the earth's centre; they would fall always parallel to the earth's axis, and the inhabitants of the northern hemisphere might explain this as arising from a force of repulsion inherent in the pole star. If the earth rotated many times faster even than this, bodies would fall always perpendicularly away from the earth's axis, and this might be interpreted as arising from a gravitational repulsion residing in the earth's axis.

These illustrations will show that it is easy to confuse acceleration arising from the earth's rotation with gravitational attraction. We may go further and say that it is impossible to distinguish between the effects of gravitational attraction and the effects of acceleration of any kind whatever. Every aviator knows this to his sorrow; it is inherently impossible to devise any instrument which shall show the direction of the vertical in an aeroplane since an acceleration of the aeroplane produces on any instrument whatever, effects which are indistinguishable from those of gravity. From such considerations Einstein was led to his principle of equivalence, which may be enunciated as follows:—

"A gravitational field of force at any point of space is in every way equivalent to an artificial field of force resulting from acceleration, so that no experiment can possibly distinguish between them."

Guided by these two principles—relativity and equivalence—Einstein was led to the view that all gravitational "fields of force" must be illusions. The apparent "force" arises solely from acceleration and there is no other kind of gravitational force at all. In this statement, as in the statement of the principle of equivalence above, the word acceleration is used in its widest sense. Acceleration results not only from change in the amount of a velocity, but from a change in its direction also. For instance a motorcyclist riding in a circle at a uniform speed of 60 mi. an hour will be the subject of an acceleration towards the centre of the circle. He knows that the apparent force so produced is just as real in its effects as gravitation, and to save himself from falling as a result of its influence he must incline the direction of his

machine to the vertical.

It is clear that the acceleration or curvature of path which figures as gravitation cannot be an acceleration or curvature in ordinary three-dimensional space. Before the apple starts to fall from the tree there is neither acceleration nor curvature and yet the apple is undoubtedly acted on by gravitation. Moreover, this three-dimensional space is, as we have seen, different for different observers—it is a subjective and not an objective conception, and the gravitation resulting from such a curvature could not conform to the relativity condition. Einstein was accordingly led to suppose that gravitation arose from curvature in the four-dimensional space, or continuum, in which time formed the fourth dimension. This continuum, as has been seen, is objective and if the path of the particle can also be made objective, the resulting gravitation will conform to the relativity principle. The path of the particle in the continuum is, however, simply its "world line," which we have already had under discussion. This world line is determined by natural laws, and if these are to be objective the specification of the world line must also be objective. There is, however, only one specification of world lines in the continuum which is objective in the sense that the same specification will give the same world lines to observers moving with different velocities. It is that every world line must be so drawn as to represent the shortest path between any two points on it. Mathematically, lines which satisfy this condition are known as *geodesics*. Thus Einstein was led to suppose that world lines must be geodesics in the four-dimensional continuum.

Consider for a moment a page of this volume as presenting a two-dimensional analogy of the continuum. The shortest distance between any two points is of course the straight line joining them, so that the geodesics are simply straight lines. These possess no curvature of path, and if they formed a true analogy to the geodesics in the continuum there could clearly be no explanation of gravitation of the type we have been contemplating. There is, however, another type of two-dimensional surface. It is represented by the surface of a solid body such as a sphere—say the earth. On the earth's surface the geodesics are the great circles; every mariner or aviator who desires to sail the shortest course between two points sails along a great circle. To take a definite instance, the shortest course from Panamá to Ceylon is not along the parallel of lat. (about 9°N.) which joins them—the aviator who wishes to fly the shortest course between the two countries will fly northeast from Panamá, he will pass over England and finally reach Ceylon from the northwest. The reader may rapidly verify this by stretching a thread tightly over the surface of an ordinary geographical globe. Let him now trace out the course on an ordinary Mercator chart, and it will be found to appear very curved indeed—the course of the aviator will look surprisingly like that of a comet describing an orbit under the attraction of a sun situated somewhere near the middle of the Sahara.

The reader who performs these simple experiments will understand how Einstein was led to suppose that gravitation could be explained by a curvature inherent in the continuum. The world lines of particles are geodesics but the space itself, so to speak, provides the curvature. The curvature of path is thrust upon the particle by the nature of the continuum, but we, who until recently have been unaware even of the existence of the continuum, have been tempted to ascribe it to the action of a special agency which we have invented *ad hoc* and called "gravitation." According to Einstein's view of the nature of gravitation, it is no more accurate to say that the earth attracts the moon than to say that the pockets of an uneven billiard table attract or repel the balls.

Perhaps this train of thought may seem artificial. If so, the reason is that we have not been able to explore the other possibilities which have branched off our main line of thought. In point of fact, Einstein found himself practically limited to the conclusion we have stated. Not only so, but the actual type and degree of curvature in the continuum prove to be uniquely fixed in terms of the masses of the gravitating bodies. Thus Einstein, knowing the mass of the sun, found himself in a position to predict absolutely what the motion of the perihelion of Mercury must be. It was found to be 42.9" a century, a figure

which agreed with observation to well within the limits of error of the observations. The motions of the other planets as predicted by the theory of relativity, have also been found to agree with those observed to within the errors of observation. This latter test is not a very stringent one, since the departures from the motion predicted by the Newtonian law are too small to admit of very precise measurement.

Effect of Gravitation on Light.—Einstein's theory requires that the world line of a ray of light also shall be a geodesic in the continuum. In interstellar space and regions remote from gravitating masses, this merely means that light travels in straight lines. But a star or other massive body distorts the continuum in its neighbourhood by an amount which is proportional to its mass. In the neighbourhood of such a body a ray of light does not travel in a straight line; it is deflected by the gravitational field of the body by an amount which is directly proportional to the mass of the body, and also, of course, depends on how closely the ray approaches the body. Einstein calculated that a ray of light which comes from a distant star and passes near the edge of the sun on its journey must be bent, in its passage past the sun, by an angle which should be $1.745''$ if the ray just grazes the sun, and would be less, in proportion to the inverse distance from the centre of the sun, for other rays.

The observatories of Greenwich and Cambridge dispatched expeditions to test this prediction at the eclipse of 1919. It was found that the stars which appeared near to the sun at the instant of eclipse showed an appreciable displacement, as compared with their normal positions, of the type required by Einstein's theory. Exact measurement confirmed that the displacement varied approximately as the inverse distance from the sun, and that the displacement at the limb was sensibly equal to Einstein's predicted value of $1.745''$. The Cambridge observers, hampered by cloudy weather, obtained for this quantity the value $1.61''$ but with a probable error of $0.30''$. The Greenwich observers obtained a value of $1.98''$ with a probable error of $0.12''$, but Prof. H. N. Russell subsequently pointed out that their photographs contained intrinsic evidence of a horizontal and vertical scale difference of the order of one part in 12,000 almost certainly due to a distortion of the coelostat mirror under the sun's rays, and if the measures are corrected for this the result is brought much closer to the theoretical prediction. Three years later an expedition, sent out by Lick observatory to observe the 1922 eclipse, was favoured by good weather and obtained for the displacement at the sun's limb, a value of $1.72''$ with a probable error of $0.11''$. On the other hand, Potsdam observers at the Sumatra eclipse of 1929 found a deflection of $2.2''$ instead of the predicted value of $1.75''$; and E. Freundlich inferred from a re-examination of the Lick observations of 1922 that they agreed with this. The question must be regarded as still unsettled in 1945. None of the expeditions had of course measured the deflections of stars actually at the sun's limb; most of the stars were several diameters away from the limb, the observed deflections being corrected so as to bring them to the limb.

The Gravitational Shift of Spectral Lines.—The theory makes one further prediction which admits of experimental test. The atoms of any element, say calcium, may be supposed to be formed according to a definite specification, the terms of which depend neither on the velocity of a particular observer nor on his position relative to the gravitational fields of the universe. It can be deduced that the light received from a calcium atom situated in the intense gravitational field near the sun's surface ought to be of slower period, and therefore of redder colour, than the similar light emitted by terrestrial atoms. To be more precise, the Fraunhofer lines in the solar spectrum ought to show a displacement to the red; this displacement ought to be homologous, and should be of amount 0.008 \AA units at the cyanogen band $\lambda 3883$ at which observations have been chiefly made. Early attempts to test this prediction led to strangely discordant results. All observers found some effect of the kind predicted, but its amount was generally substantially less than the predicted amount, varying from almost *nil* (Charles E. St. John, 1917) to nearly the full amount to be expected (John Evershed, 1918 and 1923,

L. Grebe and Albert Bachem, 1919). The latest measurements of the displacement are those of Evershed (1927). Measuring the mean displacement shown by the lines of 29 prominences, Evershed found that the H and K lines of calcium showed the same mean displacement of 0.009 \AA , as compared with 0.008 \AA required by theory.

The want of success of the earlier observations is explained by the circumstance that the relativity shift of 0.008 \AA is liable to be masked by larger shifts of uncertain amount arising from other causes. Larger shifts would be expected in stars which were of larger mass than the sun or of smaller radii. Many known stars have masses far larger than the sun, but they also have larger radii, and so ought to show only about the same spectral shift as the sun. On the other hand the class of stars known as "white dwarfs" have masses comparable with that of the sun, but far smaller radii. For instance, calculation shows that the companion to Sirius, a star whose radius is only about $\frac{1}{25}$ of that of our sun, ought to show a shift of as much as 0.30 \AA . On putting the matter to the test at Mount Wilson observatory, Walter S. Adams found an actual shift of 0.32 \AA . It is not possible any longer to doubt that the spectral shift predicted by Einstein really exists.

ELECTROMAGNETIC FORCES

The restricted physical theory of relativity introduced a revolution into the foundations of scientific thought by destroying the objectivity of time and space. The gravitational theory has effected a hardly less important revolution by destroying our belief in the reality of gravitation as a "force." The physicist has, however, to deal with other "forces" besides those of gravitation, namely, the electromagnetic forces which are concerned in all electrical, magnetic and chemical phenomena, and the question inevitably arises as to whether these also must be regarded as illusions, arising only from our faulty interpretation of the special metrical properties of the continuum. Analysis makes it clear that the continuum as imagined by Einstein has no capacity for simulating any forces beyond those of gravitation. If electromagnetic forces are evidence of special geometrical properties of the continuum, then the continuum is more complicated even than Einstein imagined.

In a brilliant paper published in 1918 (*Berlin Sitzungsber.*, p. 465 [1918]) Hermann Weyl proved that Einstein's geometry is far from being the most general geometry which is consistent with the general principle of relativity, and showed that certain at least of the forces of electromagnetism could be explained very naturally by adding an extra degree of complexity to the geometry of the continuum. In the continuum as imagined by Einstein, the length of a measuring rod might change as it was moved about in a gravitational field, but its length at any instant would depend solely on its position in space. In the geometry of Weyl, this concept of length is abandoned—that is to say, a vector with given components at a given point no longer has a definite length, but the concept of length is admitted in a modified form; namely, when by an arbitrary act of choice we have fixed the meaning of the word "length" at a point P , we can derive a definite meaning for the word "length" at a neighbouring point P' , provided a certain vector function of position is given. And this vector function is identified by Weyl with the electromagnetic potential-vector.

In 1921 Eddington extended Weyl's geometry into a still more general system of geometry, in which even lengths at the same point were not assumed to be capable of direct comparison. This geometry had a certain advantage over Weyl's original geometry in that the terms which were ultimately called on to explain electromagnetic phenomena occurred naturally as a necessary development of the geometry. In Weyl's geometry the necessary terms are shaped to fill a gap, and it is then found that they fit exactly. In Eddington's geometry no shaping is necessary, or, rather, the shaping process is performed off the stage or before the curtain rises. The gravitational and electromagnetic forces are accounted for by the symmetrical and antisymmetrical parts of a single tensor, so that an electromagnetic field appears almost to be a necessary accompaniment to a gravitational field. But

Eddington's geometry, like that of Weyl, predicts precisely the same phenomena as James Clerk Maxwell's classical electromagnetic theory, so that experimental test is impossible.

Both these geometries are successful in interpreting the electromagnetic field in free space in terms of geometry, but show less success in interpreting the ponderomotive forces on charged bodies, electrons, protons, etc. Many other forms of unified field theory were published after 1930; but none of them won general acceptance from theoretical physicists, although many of them furnished contributions of great value to the pure mathematical science of differential geometry.

In 1943, however, Erwin Schrödinger remarked that a method of unifying the gravitational and electromagnetic fields which had been proposed in 1923 by Einstein, but afterward abandoned, was worthy of renewed attention; and in a series of papers in 1943-44 he showed that it was capable of representing mathematically the "meson-field" as well as the gravitational and electrical fields. Another attempt at a unified theory is a theory of "bivector fields," put forward by Einstein and V. Bargmann in 1944, and developed in 1945 by Schrödinger and F. Mautner. In this the fundamental field variables, unlike the gravitational potentials of Einstein's original theory, depend on the combination of the coordinates of two points.

The Position of the Ether.—It is clear that the doctrine of relativity must profoundly affect our views of the ether and its function in the scheme of the universe. At one stage in the history of science, there was a tendency to imagine space filled with innumerable ethers, to the extent almost of one ether for every set of phenomena requiring explanation. That stage passed, and by the end of the 19th century only one ether received serious consideration, the so-called electromagnetic ether of Michael Faraday and Maxwell. This ether gave a plausible mechanical explanation of electrostatic phenomena, although it was more than doubtful whether it could account for the electromagnetic phenomena from which it took its name, and it was comparatively certain that it could not account for gravitation. It gave, however, a satisfactory explanation of the propagation of waves of light—they were simply waves in the ether which travelled with an absolute velocity c determined once and for all by the structure of the ether. On this view it was quite certain that an observer moving through the ether with a velocity v would measure the velocity of light travelling in the same direction as himself as $c-v$. Relativity, teaching that this velocity is always precisely c , dismisses the particular type of ether imagined by Faraday and Maxwell. Whether any new ether will be devised to replace it remains to be seen, but none appears to be necessary. Any ether which can be imagined would appear to depend upon an objective separation of time and space. Relativity does not deny that such an objective separation may, in the last resort, really exist, but it shows that no material phenomena are concerned with such a separation. By a very slight turn of thought, the primary postulate of relativity may be expressed in the form that the material world goes on as though no ether existed.

To the relativist the essential background to the picture of the universe is not the varying agitation of a sea of ether in a three-dimensional space but a tangle of world lines in a four-dimensional space. Only the intersections of the world lines are important. An intersection at a point in the continuum represents an event, while the part of a world line which is free from intersections represents the mere uneventful existence of a particle or a pulse of light. And so, since our whole knowledge of the universe is made up of events, it comes about that the tangle of world lines may be distorted and bent to any degree we please; so long as the order of the intersections is not altered, it will still represent the same universe. Thus the last function of the ether, that of providing a scale of absolute measurements in space, becomes a superfluity. To the physicist who urges that space measurements without an underlying ether become meaningless, the relativist can reply that time-measurements without an underlying "time-ether" are equally meaningless. A "time-ether" has never been regarded as a necessity, and the relativist may fairly argue that the "space-ether" has no greater claim to retention.

Probably, however, final judgment on this, as on other similar questions, must be suspended until the position of electromagnetic forces in the general scheme of relativity is better understood than it is now.

COSMOLOGY

According to the simple views of space and time which prevailed before the advent of relativity, time had no properties except duration, and space had no properties except extension. Every instant of time was, in its essence, precisely similar to every other instant of time, so that time must go on forever unless it was stopped by something different from time; it could not end of itself, for this would require the last instant of time to have different properties from all other instants of time. Similarly all elements of space were supposed to be intrinsically of the same nature and to have Euclidean properties, which required that space should extend to infinity in all directions.

Einstein's theory of relativity changed all this. According to this theory the space-time in the neighbourhood of a gravitating mass is essentially different from space-time which is far away from all masses; the former is curved, while the latter, at least if all gravitating masses are infinitely far away, is not. The curvature of the space-time in the neighbourhood of the sun causes the planets to describe ellipses, whereas if all masses were infinitely removed, they would describe straight lines. When it is once admitted that all elements of space-time are not intrinsically similar, no reason remains either why space should be of infinite extent or why time should be of infinite duration.

In 1917 Einstein added to the differential equations of the gravitational field a term containing a constant which is called the "cosmical constant." The effect of this term is to cause a mutual repulsion or scattering of the stars, which is opposed by their gravitational attraction or tendency to aggregate. If we consider a universe occupied by material particles (representing the stars), the presence of the matter produces a curvature of the space, and a solution exists in which the space is closed (*i.e.*, finite in volume), the density of matter and the radius of curvature being constant and uniform and the gravitational attraction being balanced exactly by the cosmical repulsion, so that the system remains permanently at rest in equilibrium. This is called an "Einstein universe."

Besides the Einstein world there is another solution of the equations which likewise is static (*i.e.*, it does not vary with time), discovered by Willem de Sitter and known as the "De Sitter universe": this is entirely empty of matter. Certain non-static types of universe found by G. A. Friedman and the abbé G. Lemaitre are intermediate between Einstein's and De Sitter's; and it was shown by Eddington in 1930 that the Einstein universe is unstable and, when disturbed, assumes in succession forms of these intermediate types, the volume continually increasing. This is the theory of the "expanding universe." In the limit when the expansion has reduced the density so much that the mutual influences of the particles are negligible, the universe tends to the De Sitter type.

An observer situated on any one of the particles (*i.e.*, stars) would see all the other particles receding from him on account of the expansion, the rate of recession increasing uniformly with the distance, since the universes at different times are geometrically similar to each other; if a is the distance of another star at time t , the quantity $\frac{1}{a} \frac{da}{dt}$ tends to a fixed limit as the expansion proceeds, and this limit was shown by Lemaitre to be the $\frac{c}{R\sqrt{3}}$

where R denotes the radius of curvature of the Einstein world and c the velocity of light. This remarkable theory is confirmed by the observed recession of the extra-galactic nebulae, which is exactly of the type predicted. By combining measurements of the recession with Lemaitre's formula, the value of R can be obtained; it is found to be of the order of 10^{27} cm.

The total mass M of the universe may then be deduced by use of a formula derived from the theory of the Einstein world, namely,

$$\gamma M = \frac{3}{2} \pi c^2 R$$

where γ denotes the Newtonian constant of gravitation and c

the velocity of light. The value of the mass of the universe thus obtained is of the order of 10^{55} gr. These values of R and M have been independently confirmed by other investigations of Edgington.

Non-mathematicians are liable to misunderstand the nature of the expanding universe, conceiving of it as being like a globular star cluster which is expanding into the empty space around it. This is wrong; there is no empty space around the material universe. At any instant, the whole of space is occupied by matter of (on the average) uniform density; but space is closed and of finite volume (proportional to the cube of its radius of curvature at the instant), and it is this volume which is expanding.

In 1933 a new type of cosmological research was initiated by Edward A. Milne. He considered a universe of particles, and described two particle observers A and B as "equivalent" when the totality of observations A can make on B can be described by A in the same way as the totality of observations which B can make on A can be described by B. The universe is then said to satisfy the "cosmological principle" when, if A and B are two equivalent members of the system, A's description of the whole system (in terms of his clock-measures or associated co-ordinates) is identical with B's description of the whole system (in terms of B's clock-measures or associated co-ordinates). Milne has deduced the fundamental properties of a universe which satisfies the cosmological principle, obtaining a comprehensive theory of dynamical, gravitational and electromagnetic phenomena. Some of his conclusions are discussed in the article SPACE-TIME.

PROGRESS IN OTHER DIRECTIONS AFTER 1930

In 1931 and following years the concept of distance in curved space-time and the displacement of the spectral lines of distant sources was examined, with special reference to the relation between theoretical expressions and observed quantities. If an observer O in a general space-time makes an assertion regarding the "spatial distance" of a star S from himself, he is really stating a relation between the world point of S at the instant when light left it, and his own world point at the instant when the light arrives. In other words, he is dealing with a relation between two world points which lie on the same null geodesic. This statement brings into sharp relief the contrast between spatial distance and the "interval" of general relativity; for between two points on the same null geodesic the interval is always zero. Thus, spatial distance exists when, and only when, the interval is zero.

Now the distance of a remote star from the earth is generally determined by finding the square root of the ratio of its absolute brightness to its apparent brightness (i.e., the brightness as actually seen by the observer), and the translation of this method into the language of geometry furnished a definition of spatial distance which was given by Whittaker in 1931 and led to the subsequent developments. It may be expressed as follows: the spatial distance between a star S and an observer O (on the same null geodesic) is proportional to the square root of the two-dimensional cross section made by a thin pencil of null geodesics, with vertex S and passing near O, on the instantaneous three-dimensional space of the observer. The factor of proportionality is fixed by requiring that when O and S are near one another the spatial distance shall reduce to the ordinary Euclidean distance.

An important book published by Richard C. Tolman in 1934 under the title *Relativity, Thermodynamics and Cosmology* broke fresh ground in many directions, particularly in the formulation of the second law of thermodynamics in general relativity. He showed *inter alia* that the tendency of a system undergoing irreversible changes, to attain a final state of maximum entropy, can no longer be regarded as inevitable in all cases.

In a series of memoirs published from 1928 to his death in 1944 Edgington developed his work on relativity in an entirely new direction, leading ultimately to a complete revision of the foundations of physics. His first achievement was to predict that the reciprocal of the fine-structure constant must have the exact value 137 —a result which seemed at the time to be irreconcilable with the observed value, but which is now generally accepted.

Subsequently, he found a quadratic equation whose roots are the masses of the proton and the electron, a theoretical value for the ratio of the gravitational to the electrostatic force between a proton and an electron, and predictions of many other natural constants, connecting in a remarkable way the properties of the atom with the structure of the cosmos. As a mathematical tool for the purposes of the investigation he devised a noncommutative algebra with 16 units, which may be described as the square of quaternion algebra. The theory in its definitive form is given in his posthumous book.

The extremely difficult problem of n bodies in general relativity was advanced somewhat in 1938 by Edgington and G. L. Clark, who succeeded in evaluating the "total mass" of a system of particles which are in relative motion and which interact with each other. They defined the mass M of the system as equal to the mass of a single particle, having the position and acceleration of the centre of the mass, which would produce the same gravitational field at a great distance from the system. If M is changing, the time to which this value refers is earlier than the time of comparison at the distant point by the time taken by light to traverse the intervening distance. With this definition, the formula established is

$$M = M_0 + 3K + 2V$$

where M_0 is the sum of the proper-masses of the particles, K the kinetic energy and V the internal potential energy. This theorem interprets and amplifies the general statement that "mass is energy"; but though it can be obtained only after lengthy calculations, it is only an approximation, and there is much need for further investigation on the subject.

In 1942-44 George D. Birkhoff originated a new theory of matter, electricity and gravitation, in which matter was taken to be a perfect fluid in the flat space-time of special relativity, the velocity of disturbance in the matter being that of light. On this theory he was engaged at the time of his death in Nov. 1944; it has been further developed by Manuel Vallarta and others (*Proc. Nat. Ac. Sci.*, 1943 and 1944; *Phys. Rev.*, 1944).

BIBLIOGRAPHY.—In the first place should be named a series of seven books published in succession during 24 years by Sir Arthur Eddington: *Space, Time, and Gravitation* (1921), *The Mathematical Theory of Relativity* (1923), *The Nature of the Physical World* (1928), *The Expanding Universe* (1933), *Relativity Theory of Protons and Electrons* (1936), *The Philosophy of Physical Science* (1939), *The Constitution of Relativity Theory and Quantum Theory* (1943). A posthumous book, *Fundamental Theory*, was published in 1948.

Other works, whose point of view or subject matter differs from that of Eddington's books are: E. A. Milne, *Relativity, Gravitation, and World-Structure* (1935); H. P. Robertson, "Relativistic Cosmology," *Rev. Mod. Phys.*, 5: 62 (1933); E. Schrödinger, *Proc. R. Irish Acad.*, 49 (1943-44), 50 (1945); R. C. Tolman, *Relativity, Thermodynamics, and Cosmology* (1934); A. N. Whitehead, *The Principles of Relativity* (1922); E. T. Whittaker, "The Outstanding Problems of Relativity," *Nature*, 120 (1927). A textbook of the mathematical theory is R. G. Bergmann, *Introduction to the Theory of Relativity* (1942). (J. H. J.; E. Ws.)

RELATIVITY: PHILOSOPHICAL CONSEQUENCES. Of the consequences in philosophy which may be supposed to follow from the theory of relativity ($q.v.$), some are fairly certain, while others are open to question. There has been a tendency, not uncommon in the case of a new scientific theory, for every philosopher to interpret the work of Albert Einstein in accordance with his own metaphysical system, and to suggest that the outcome is a great accession of strength to the views which the philosopher in question previously held. This cannot be true in all cases; and it may be hoped that it is true in none. It would be disappointing if so fundamental a change as Einstein has introduced involved no philosophical novelty. (See SPACE-TIME.)

Space-time.—For philosophy, the most important novelty was present already in the special theory of relativity; that is, the substitution of space-time for space and time. In Newtonian dynamics, two events were separated by two kinds of interval, one being distance in space, the other lapse of time. As soon as it was realised that all motion is relative (which happened long before Einstein), distance in space became ambiguous except in the case of *simultaneous* events, but it was still thought that there was no ambiguity about simultaneity in different places. The special theory of relativity showed, by experimental argu-

ments which were new, and by logical arguments which could have been discovered any time after it became known that light travels with a finite velocity, that simultaneity is only definite when it applies to events in the same place, and becomes more and more ambiguous as the events are more widely removed from each other in space.

This statement is not quite correct, since it still uses the notion of "space." The correct statement is this: Events have a four-dimensional order, by means of which we can say that an event A is nearer to an event B than to an event C; this is a purely ordinal matter, not involving anything quantitative. But, in addition, there is between neighbouring events a quantitative relation called "interval," which fulfils the functions both of distance in space and of lapse of time in the traditional dynamics, but fulfils them with a difference. If a body can move so as to be present at both events, the interval is timelike. If a ray of light can move so as to be present at both events, the interval is zero. If neither can happen, the interval is spacelike. When we speak of a body being present "at" an event, we mean that the event occurs in the same place in space-time, as one of the events which make up the history of the body; and when we say that two events occur at the same place in space-time, we mean that there is no event between them in the four-dimensional space-time order. All the events which happen to a man at a given moment (in his own time) are, in this sense, in one place; for example, if we hear a noise and see a colour simultaneously, our two perceptions are both in one place in space-time.

When one body can be present at two events which are not in one place in space-time, the time-order of the two events is not ambiguous, though the magnitude of the time-interval will be different in different systems of measurement. But whenever the interval between two events is spacelike, their time-order will be different in different equally legitimate systems of measurement; in this case, therefore, the time-order does not represent a physical fact. It follows that, when two bodies are in relative motion, like the sun and a planet, there is no such physical fact as "the distance between the bodies at a given time"; this alone shows that Isaac Newton's law of gravitation is logically faulty. Fortunately, Einstein has not only pointed out the defect, but remedied it. His arguments against Newton, however, would have remained valid even if his own law of gravitation had not proved right.

The fact that time is private to each body, not a single cosmic order, involves changes in the notions of substance and cause, and suggests the substitution of a series of events for a substance with changing states. The controversy about the ether thus becomes rather unreal. Undoubtedly, when light waves travel, events occur, and it used to be thought that these events must be "in" something; the something in which they were called the ether. But there seems no reason except a logical prejudice to suppose that the events are "in" anything. Matter, also, may be reduced to a law according to which events succeed each other and spread out from centres; but here we enter upon more speculative considerations.

Physical Laws.—Prof. Arthur S. Eddington emphasized an aspect of relativity theory which is of great philosophical importance, but difficult to make clear without somewhat abstruse mathematics. The aspect in question is the reduction of what used to be regarded as physical laws to the status of truisms or definitions. Prof. Eddington, in an essay on "The Domain of Physical Science," stated the matter as follows:

In the present stage of science the laws of physics appear to be divisible into three classes—the identical, the statistical and the transcendental. The "identical laws" include the great field-laws which are commonly quoted as typical instances of natural law—the law of gravitation, the law of conservation of mass and energy, the laws of electric and magnetic force and the conservation of electric charge. These are seen to be identical, when we refer to the cycle so as to understand the constitution of the entities obeying them; and unless we have misunderstood this constitution, violation of these laws is inconceivable. They do not in any way limit the actual basal structure of the world, and are not laws of governance (*op. cit.*, pp. 214-215).

It is these identical laws that form the subject-matter of relativity theory; the other laws of physics, the statistical and transcendental, lie outside its scope. Thus the net result of rela-

tivity theory is to show that the traditional laws of physics, rightly understood, tell us almost nothing about the course of nature, being rather of the nature of logical truisms.

This surprising result is an outcome of increased mathematical skill. As the same author said elsewhere:

In one sense deductive theory is the enemy of experimental physics. The latter is always striving to settle by crucial tests the nature of the fundamental things; the former strives to minimise the successes obtained by showing how wide a nature of things is compatible with all experimental results.

The suggestion is that, in almost any conceivable world, *something* will be conserved; mathematics gives us the means of constructing a variety of mathematical expressions having this property of conservation. It is natural to suppose that it is useful to have senses which notice these conserved entities; hence mass, energy, and so on *seem* to have a basis in our experience, but are in fact merely certain quantities which are conserved and which we are adapted for noticing. If this view is correct, physics tells us much less about the real world than was formerly supposed.

Force and Gravitation.—An important aspect of relativity is the elimination of "force." This is not new in idea; indeed, it was already accepted in rational dynamics. But there remained the outstanding difficulty of gravitation, which Einstein has overcome. The sun is, so to speak, at the summit of a hill, and the planets are on the slopes. They move as they do because of the slope where they are, not because of some mysterious influence emanating from the summit. Bodies move as they do because that is the easiest possible movement in the region of space-time in which they find themselves, not because "forces" operate upon them. The apparent need of forces to account for observed motions arises from mistaken insistence upon Euclidean geometry; when once we have overcome this prejudice, we find that observed motions, instead of showing the presence of forces, show the nature of the geometry applicable to the region concerned. Bodies thus become far more independent of each other than they were in Newtonian physics: there is an increase of individualism and a diminution of central government, if one may use such metaphorical language. This may, in time, modify the ordinary educated man's picture of the universe, possibly with far-reaching results.

Realism in Relativity.—It is a mistake to suppose that relativity adopts an idealistic picture of the world—using "idealism" in the technical sense, in which it implies that there can be nothing which is not experience. The "observer" who is often mentioned in expositions of relativity need not be a mind, but may be a photographic plate or any kind of recording instrument. The fundamental assumption of relativity is realistic, namely, that those respects in which all observers agree when they record a given phenomenon may be regarded as objective, and not as contributed by the observers. This assumption is made by common sense. The apparent sizes and shapes of objects differ according to the point of view, but common sense discounts these differences. Relativity theory merely extends this process. By taking into account not only human observers, who all share the motion of the earth, but also possible "observers" in very rapid motion relatively to the earth, it is found that much more depends upon the point of view of the observer than was formerly thought. But there is found to be a residue which is not so dependent; this is the part which can be expressed by the method of "tensors." The importance of this method can hardly be exaggerated; it is, however, quite impossible to explain it in nonmathematical terms.

Relativity Physics.—Relativity physics is, of course, concerned only with the quantitative aspects of the world. The picture which it suggests is somewhat as follows: In the four-dimensional space-time frame there are events everywhere, usually many events in a single place in space-time. The abstract mathematical relations of these events proceed according to the laws of physics, but the intrinsic nature of the events is wholly and inevitably unknown except when they occur in a region where there is the sort of structure we call a brain. Then they become the familiar sights and sounds and so on of our daily life. We know what it is like to see a star, but we do not know the nature of the events which constitute the ray of light that travels from the star to our eyes. And the space-time frame itself is known only in its

abstract mathematical properties; there is no reason to suppose it nilar in intrinsic character to the spatial and temporal relations our perceptions as known in experience. There does not seem any possible way of overcoming this ignorance, since the very nature of physical reasoning allows only the most abstract inferences, and only the most abstract properties of our perceptions can be regarded as having objective validity. Whether any other science than physics can tell us more does not fall within the scope of the present article.

Meanwhile, it is a curious fact that this meagre kind of knowledge is sufficient for the *practical* uses of physics. From a practical point of view, the physical world only matters in so far as it affects us, and the intrinsic nature of what goes on in our absence is irrelevant, provided we can predict the effects upon ourselves. This we can do, just as a person can use a telephone without understanding electricity. Only the most abstract knowledge is required for practical manipulation of matter. But there is a grave danger when this habit of manipulation based upon mathematical laws is carried over into our dealings with human beings, since they, unlike the telephone wire, are capable of happiness and misery, desire and aversion. It would therefore be unfortunate if the habits of mind which are appropriate and right in dealing with material mechanisms were allowed to dominate the administrator's attempts at social constructive.

RELEASE, in law, the term applied to the discharge of some obligation, by which it is extinguished (see *DEBT*), and to the conveyance of an estate or interest in real or personal property to one who has already some estate or interest therein. For the special form of conveyancing known as "lease and release," see **LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS: Leases**.

RELICS, any objects once connected with the person of a departed saint, especially the body or parts of the body. Veneration of relics, though not foreign to Oriental Church practice, usually refers to a custom proper to the Roman Catholic Church. St. Thomas Aquinas formulates the doctrinal principles thus: "It is clear . . . that he who has a certain affection for anyone, venerates whatever of his is left after death, not only his body and the parts thereof, but even external things, such as his clothes and such-like. Now it is manifest that we should show honour to the saints of God, as being members of Christ, and children and friends of God, and our intercessors. Wherefore in memory of them we ought to honour any relics of theirs in a fitting manner: principally their bodies, which were temples, and organs of the Holy Spirit dwelling and operating in them, and are destined to be likened to the body of Christ by the glory of the resurrection. Hence God Himself fittingly honors such relics by working miracles at their presence." (*Summa Theol.*, III, q. 25, art. 6.)

The council of Trent, in its 25th session, solemnly affirmed the same doctrine, while condemning those who hold the practice in contempt (H. J. Schroeder, *Canons and Decrees of the Council of Trent*, original text with English translation, pp. 215-217), and modern canonical legislation was framed in accordance with these principles (*Codex Iuris Canonici*, especially canons 1276-89). It is noted expressly that relics are to be honoured with a veneration that looks beyond the relics to the saints themselves, whom the relics commemorate (canon 1255 § 2). Further prescriptions attempt to assure the authenticity of relics exposed for public veneration (canons 1283-86); the fabrication of false relics, their sale or distribution, or their exposition for public veneration involves *ipso facto* excommunication (canon 2326). The Old Testament refers to the cult of relics, in the religious character of the burial of saintly persons (Gen. xxv, 19, 20; 1, 25, 26; Exod. xiii, 19), in the miraculous power of Elias' mantle (IV Kings, ii, 13, 14) and the bones of Elisha (*ibid.*, xiii, 21); but the practice assumes its definitive form in the New Law (see Matt. ix, 20-22; Acts xix, 11, 12). St. John Chrysostom refers frequently to the relics of the martyrs as sources of divine favours (Eulogy of St. Eustathius, *Migne, Patrol. Graec.*, I, 600; Homily on the Martyrs, *ibid.*, 648, 649; Eulogy of St.

Julian, *ibid.*, 670-672). St. Augustine was an ardent promoter of the practice (for example in *De Civitate Dei*, *Migne, Patrol. Lat.*, XII, 255), and indeed all the great doctors of early Christianity extolled the veneration of the relics of the saints. While it was perhaps inevitable that error, fraud and greed for gain should have led to grave abuses in this matter, ecclesiastical authority has always stood against such abuses. They were condemned for example by the Fourth Lateran council in 1215 (Denzinger *et al.*, *Enchiridion Symbolorum*, n. 440), by the council of Trent, and are prohibited by modern canon law, as noted above. The practice itself is to be understood and judged in the light of its doctrinal foundations, rather than by such failings of the uncritically devout or the deliberately malicious.

See art. "Reliques" in *Dictionnaire apologetique de la foi catholique*, IV, 909-30; *Dictionnaire de théologie catholique*, XIII, 2311-76; modern legislation in *Codex Iuris Canonici* canons 1276-89; historical data in *Lexikon für Theologie und Kirche*, VIII, 807-12, art. "Reliquien"; also *Catholic Encyclopedia*, XII, 320, "Relics" (H. Thurston); essential points of doctrine in the council of Trent, sess. 25; cf. *Canons and Decrees of the Council of Trent*, by H. J. Schroeder (Heider, 1947).

RELIEF, in sociology, the word *relief* which has come to possess a technical significance is very old, even in the derivative usage of giving to those who otherwise would suffer. It is contrasted with work and with social insurance as a method of taking care of the unemployed and other dependents, and there are wide differences of opinion on the relative merits of these three ways of supporting the destitute. There was the practice of relief, depending on a real need, before unemployment in our sense was known. When income stops, and savings are exhausted, relief must be furnished to prevent suffering if not actual death. In ages and places of simpler social organization, relief was given by members of a community to each other. The customs, even in the United States, of reciprocal aid in rural communities; the way minority groups so widely diverse as Chinese, Negro and Jewish take care of their own; the widespread methods of taking care of dependency among the Polynesians, as well as the evidence of the practice of mutual aid preserved in ancient religious writings, all bear conclusive witness to the fact that before the days of the commercial and industrial organization of society folks helped each other in their day of need.

When the practice of mutual aid was exercised in the increasingly complex urban centres—both in Europe and in North America—it did not produce the customary results; that is, giving food, or clothing or money to an otherwise unknown applicant did not seem to be of any permanent benefit to him. Assistance as a means of setting a person on his feet seemed to have lost its effectiveness.

The new element in city life which disturbed the successful practice of mutual aid seems to have been its anonymity in contrast with the intimate personal acquaintance of the small and stable community. The residents of the latter were able to individualize the practice of mutual aid on the basis of intimate personal acquaintance. Although this analysis was not made until very recently, it is not surprising that one of the first tests of eligibility for relief was residence. In fact residence was in an informal manner almost always a condition of aid. Strangers in need were rarely treated with anything but neglect or even brutality; about the only exceptions to this rule being among folks who rarely saw a stranger, like the Polynesians before James Cook's voyage. Another striking exception was furnished by religious charities such as the hospices of St. Bernard on the passes over the Alps. However, it is to be noted in the latter case, it is not an example of the extension of mutual aid to strangers, but the church stepping in to make good the failure of mutual aid to meet a great need.

Residence as a condition of eligibility for relief was recognized by English law before relief was provided from tax funds. In the 16th century a person begging in an English town not his place of residence might be placed in the stocks, branded, his ears or nose cut off and even enslaved. When the state, by the Elizabethan statute of 1601 assumed some responsibility for relief, residence was established as a condition, and has never been removed. The colonies that have grown to the present United States laid down the same condition governing relief, although

unlike England, as there is no central authority over police powers, there are as many laws defining residence as there are states. The matter is even more complicated than such a statement indicates. In addition to the enabling act which gives localities the legal right to raise and to spend money for general relief purposes, practically all states grant relief to special groups, by special legislative acts or even by constitutional provisions, such as pensions to army veterans, pensions to the blind, allowances to widowed mothers for their children, and assistance to the aged. Each of these carries an independent condition of residential eligibility.

The Federal Social Security Act of 1935 established uniform standards of residence qualifications for old-age assistance, mothers' allowances, and aid to the blind, but left unaffected the disparity between states on residence qualifications for general assistance. Increasing pressure on relief funds led to tightening of residence qualifications, especially among states with a year's residence requisite, California raising it to three years in 1933 and Colorado in 1939.

The original states on the Atlantic coast have longer periods necessary to qualify for relief than the later states, for example Massachusetts requires five years, whereas most states in the Mississippi river basin require but one, or none as in Kentucky.

The Committee on Uniform Laws of the American Bar association, and a Special Committee of the American Public Welfare association drew up a uniform settlement law covering general relief which they urged states to adopt, so as to insure that a person may not lose residence in going from one state to another. The Social Security act, in the provisions for old age assistance was also providing uniform residence qualifications for assistance to the aged.

If the determination of residence is complicated, it is a simple matter compared with determination of need. What the English call the "means test" is an attempt to prove a negative, and every administrator of the social services knows it is the most puzzling and unsatisfactory aspect in the field of social work. Some data throwing light upon need are demonstrable: death of wage earner, illness, imprisonment, unemployment. But absence of resources can never be proven. Out of this dilemma spring most of the public misunderstanding as well as the dissatisfaction of the beneficiaries.

The general conclusion on this aspect of eligibility for relief is that the word of the applicant must be taken. This statement is then subjected to such verification by circumstantial evidence as is available; standard of living of family, previous income, judgment of relatives and presence or absence of debts. When all is done, however, a clever applicant can hide resources. It is the judgment of administrators of relief that if the applicant is given a half decent chance to tell the truth, he is at least as likely to be accurate in the statement of his financial resources as the average person, probably more so than the income tax payer.

The amount of relief given is roughly based upon the difference between the income of the family—or of the individual—and the amount required to maintain a minimum standard of living. This principle is as old as the administration of the Elizabethan Poor law, which was a guarantee that none would starve or be naked or without shelter. The ideals of what constitute a standard of living might be very low, as they undoubtedly were at many times and places, but so have been the actual living standards.

Actual practice lags behind this ideal especially in relief to the unemployed. A minimum budget in 1939 compared very favourably with the standard which the income of a steadily employed unskilled labourer could secure, including besides food, rent, fuel and clothing, provision for medical and hygienic services, recreation and education. It was rare, however, that an administration had the money to give relief on such a basis. In the days before the depression the better established relief agencies, mostly private but some public, were able to do so, and had reached the conviction that adequate relief should be paid in cash, instead of in goods. But after the depression, and especially in unemployment relief the amount available did not make any such adequacy possible, so that the needs for food were

usually met, rent only occasionally met, clothing almost never, except in emergencies and by second hand clothing, while all other needs were neglected. On the other hand, the practice of granting relief in cash more than held its own. As the number on general relief continued to be high over considerable periods of time, there was a tendency to exclude arbitrarily certain groups such as unattached individuals, able-bodied men and women, even though they had families, and those who had been on relief continuously for a year or more, quite apart from any need they presented.

The future of relief was to be predicted in part from the present practice of relief to others than the unemployed, and to place more reliance upon the recipient to manage his own economic affairs, and in part from the probable development of social insurance for the unemployed. But in spite of the best unemployment insurance may do, there will remain a vast bulk of need presented by the unemployed, in periods of economic depression, after they have exhausted their insurance benefits which may only be met by relief.

Watson, *The Charity Organization Movement in the United States* (1922). (F. J. B.)

Federal Relief U.S.A.—There was no system of federal relief in existence when the depression began in the United States with the financial crash of 1929. Public relief was provided under state "poor laws," and was usually limited to almshouse care, medical care, burial and small amounts of outdoor relief, financed by towns and counties. In structure, social theory, and method of administration, this system of local public relief had remained practically unchanged from the 17th century days of Elizabethan England. This kind of public relief was supplemented by private charity, which in many cases had a quasi-public character.

For three years after 1929, notwithstanding the rapid growth of unemployment (which rose according to reliable estimates from 2,000,000 to 15,000,000) the federal government under the administration of President Herbert Hoover held that the relief of unemployment was a local problem, to be handled by state and local governmental resources supplemented by private charity. Two successive committees were set up by President Hoover to co-ordinate private and local governmental relief efforts—the President's Emergency Committee for Employment, and the President's Organization on Unemployment Relief. The assistant director of the latter, in a radio address in Jan. 1932, characterized the agitation for federal relief as a "popular business fallacy," and said that "England, as we are doing today in the United States, developed a sloppy sentimentalism that the government should care for its people." He deplored "the idiotic idea that it was the duty of the government to find its citizens work."

The breakdown of existing relief methods forced a modernization of relief machinery in several of the more progressive states but even this proved inadequate. Appeals for federal relief became more and more insistent. The Reconstruction Finance Corporation, a new federal agency which was making loans to distressed banks, railroads, and businesses, was authorized by congress in July 1932 to make loans for relief purposes to states and municipalities. Because of the various restrictions imposed on such relief loans, only \$80,000,000 was disbursed by Jan. 1, 1933.

The Federal Emergency Relief Administration, 1933-35.—With the inauguration of President Franklin D. Roosevelt in March 1933, the principle of federal participation in relief was immediately clarified and broadened. Instead of a financial agency making loans to states and municipalities in distress, a new social agency, the Federal Emergency Relief administration, was created in May 1933 to undertake a program of federal grants-in-aid to states. While the grants were made to the state governments, the actual administration of relief was primarily in the hands of the local communities to which the state government subgranted the available federal funds together with state appropriations where such had been made. The FEERA assumed a

ge part—in most cases the major share—of the cost, the rest borne by states and local communities.

The FERA attempted to set up minimum standards for relief administration, under penalty of withholding the federal grants. It also had authority, which it exercised only in exceptional circumstances, of directly administering federal relief in those states where it met with no co-operation. In addition, the FERA marked a portion of the grants to the states for a number of special programs, for classes of persons whose needs could not be met effectively by the general relief program. These included "unemployed" relief, education, college student aid and rural rehabilitation.

One of the prime objectives of the FERA from the very beginning was the development on a national scale of the system of work programs for employable persons that had been initiated by the more progressive state relief administrations. During the first six months, however, comparatively little was accomplished along this line because of the pressure of the more elementary needs of the unemployed for food, shelter, and clothing. The FERA undertook to see to it that every state had public relief administrations in every county, and that relief allowances to families were as adequate as possible. The early state work projects were in some cases poorly conceived, for it took time to realize that there was plenty of work the unemployed could do that would be socially useful and not compete with private industry. Supervision was sometimes poor, and there was generally a shortage of funds for materials, as only local funds—not federal moneys—could at the beginning be used for that purpose.

The Civil Works Administration, 1933-34.—The deficiencies of the local work relief programs, the critical unemployment situation, and the need of stimulating business recovery by large scale governmental expenditures prompted the president to start a new works program in the fall of 1933. This was the program of the Civil Works Administration, instituted within two weeks after the creation of the agency on Nov. 9, 1933, by the transfer of funds from the Public Works Administration. While the civil works program was directly administered by the federal government through a nationwide organization, most of the projects were initiated and sponsored by local governments.

Workers were paid on the basis of the work performed rather than on the "budgetary deficiency" basis which characterized local work relief projects.

Within two months of its organization, the civil works program reached a peak employment of 4,200,000, roughly half of the workers being taken from the relief rolls. The greater part of the program was terminated at the end of March 1934, although some minor phases were continued until July. The program resulted in total expenditures of \$951,600,000, of which the federal government contributed \$860,400,000, the local communities \$85,000,000, and the states the remainder.

Though hastily organized, the civil works program for the first time revealed the large variety of socially useful projects that could be operated with unemployed labour. Its field of activity embraced the repair and construction of roads and streets, the rehabilitation and even new construction of school buildings, recreational facilities, the building of new sanitation works, and a wide array of white-collar and service projects.

During the period of the CWA program, the FERA continued to function as an agency subsidizing the state relief agencies, although local work relief programs were very much curtailed. With the discontinuance of the CWA, the FERA, in co-operation with the states, set out to develop a more adequate work-relief program than had been in operation in 1933. Those CWA projects which had not been finished were taken over and completed. New projects were developed on the same principles. Some of the previous state work relief handicaps were removed. Thus, federal funds were made available for the purchase of materials; better supervision of projects was instituted. Employment in this program ranged from 1,100,000 in April 1934, to nearly 2,500,000 in Jan. 1935. When the program was in full operation, approximately 45% of all relief cases received work-relief benefits, while the remainder received direct relief.

Wages in the FERA work program were based on the principle of "budgetary deficiency." A relief family's sources of available private income were determined by the social service staff and deducted from the estimated budgetary needs. The principal bread-winner was then given as many hours of work as would yield the requisite income deficiency.

In the case of large families, work relief earnings were often supplemented by direct relief. In addition to this, surplus funds were sometimes furnished to general relief cases through the Federal Surplus Relief corporation, which was largely financed with FERA funds. (This later became an agency in the department of agriculture and was renamed the Federal Surplus Commodities corporation.)

In the spring of 1935 congress and the administration made an important change in the method of dealing with the problem of unemployment relief. This new method, which was originally embodied in the Emergency Relief Appropriation Act of 1935, involved, first, the turning over of direct relief to the states and local communities and, second, the setting up of a large federal works program to provide emergency employment, particularly to employable heads of families on relief rolls.

The decision to take the federal government "out of the business of relief" was taken at the moment when a comprehensive social security system was set up. This system made provision not only for unemployment and old-age insurance, but for old-age assistance, aid to the blind, and aid to dependent children, to be administered by the states with matching grants by the federal government. It was felt that once these categories of destitution were taken care of, and once the federal government assumed responsibility for the employment of employables on relief, the remaining direct relief problem could be handled by the states and local communities with their own resources.

The Works Progress Administration, 1935-39.—The new feature in the reoriented programs of 1935 was the introduction of a broad program of project work, comprising locally planned and sponsored undertakings that were, however, to be federally directed and in large measure federally financed. Workers were to be removed from the relief rolls and paid fixed monthly security wages. The security wages represented a compromise between the CWA principle of regular wages and the FERA principle of budgetary needs. Monthly wages were fixed at the same level for the same type of work regardless of family diversities, but the wages for the different classifications of skills and different regions of the country represented less than the corresponding normal earnings in private industry. Most of the work projects were directed by the newly created Works Progress Administration, which was originally intended to serve as a coordinating agency for the entire works program but which became the principal operating agency as well.

In addition to the system of work projects, the works program of 1935 continued the emergency employment programs on heavy public works carried on by the bureau of public roads and the Public Works Administration. These phases of the work program were carried on by the contract method. At first these agencies were required to see to it that contractors selected their crews as far as possible from the relief rolls—a requirement that proved difficult to enforce and was later dropped. The 1935 works program also continued the program of the Civilian Conservation Corps, which provided employment and training to needy youths between 18 and 25. Finally, it should be mentioned that a National Youth Administration was established within the WPA (by executive order), which in addition to providing aid for high school, college and graduate students developed work projects for needy youths between 16 and 25.

Although the federal government withdrew from general relief in 1935, in the popular mind the activities of the WPA were regarded as the federal government's contribution to the meeting of the relief problem. A brief discussion as to the activities and policies of this organization is therefore in order.

First as regards employment. Work on WPA projects was begun in July 1935. WPA employment increased steadily throughout the fall and winter and by Feb. 1936 it had reached a total of

more than 3,000,000 persons. Thereafter, during 1936 and 1937, as private employment increased, WPA employment decreased, reaching a low of 1,450,000 in Sept. 1937. With the business recession which developed shortly thereafter, employment on WPA-operated projects again rose and reached 3,250,000 in Oct. 1938.

By June 1939 WPA employment had declined to 2,440,000 persons. For the fiscal year July 1, 1939, to July 1, 1940, congress appropriated funds making possible an average employment of 2,000,000 persons. A glance at these employment figures indicates the extreme flexibility of the WPA organization—an ability to expand and disburse purchasing power quickly among the needy unemployed when the business situation required it, and to contract operations when private employment increased and the shortage of purchasing power decreased.

The cost of WPA operations was borne very largely by the federal government. But since the work projects concentrated on local needs, it was felt desirable that local communities should suggest and sponsor the projects that were put in operation and should at the same time pay part of the cost. In accordance with this policy the WPA limited the expenditure of federal funds in so far as possible to the payment of wages of project workers. All project nonlabour costs in excess of \$6 per man per month, the maximum allowed by law for federal funds, were to be defrayed by the project sponsors.

A few federal projects (notably the Arts projects) were operated by the WPA on a nation-wide basis with relatively small contributions from co-sponsors. The Emergency Relief Appropriation Act of 1939 provided that the WPA could not itself sponsor projects. Thereafter the Arts projects were continued where state and local governments were interested in sponsoring and sharing in the cost of the work. The theatre projects were entirely discontinued on July 1, 1939, by act of congress.

Sponsors' contributions varied with the financial resources of the community, the character of the public improvements it desires to carry out, and the gravity of the local unemployment problem. They averaged about 20% for the nation as a whole after July 1937. Beginning Jan. 1, 1940, the average of sponsors' contributions for each state was required by law to be 25% of the total cost of projects subsequently approved and initiated.

During the fiscal year 1938-39, the federal government's cost was about \$61 per man month of employment, including average wages of \$52.50 a month, materials \$6.50 and \$2.00 for administration. These costs were to be increased, though not substantially, in consequence of a revision of wage policies laid down by the congress in the 1939 appropriation act which forbade geographical differences in excess of differences in the cost of living. The new wage schedule ranged from \$31.20, the lowest unskilled wage in the rural south, to \$94.90, the highest professional wage in the cities of the north.

One of the complications in the security wage which had hitherto affected the efficiency of WPA operations was removed by the 1939 relief act. This was the requirement that prevailing hourly wages be paid on WPA projects, a requirement that necessitated the determination of monthly hours so that total earnings at the prevailing hourly wage rates would not exceed the applicable monthly security wage. This tended to result in a limited number of hours of work per month that often varied greatly between different classes of workers on the same project. Under the new provision all WPA workers had to work 130 hours a month in order to earn their security wages.

About 80% of WPA activities were in the construction field, while 20% represented goods projects (canning projects and sewing rooms for women) and white-collar projects.

There is little space here to discuss the variety or the value of WPA accomplishments. For this the reader is referred to the U.S. Community Appraisal report, representing a survey conducted by 10 independent national organizations and summarizing reports from nearly 8,000 communities. Ninety-five per cent of the reports state that WPA work was worth while and of permanent value to the community. The reader is also referred to the periodical inventories of physical accomplishments published by the WPA, which give detailed figures both as to construction

and nonconstruction projects.

The Federal Works Agency, 1939.—Under the Governmental Reorganization Act of 1939, the Works Progress administration (renamed the Work Projects administration) was consolidated with four other public works agencies (the Public Works administration, the U.S. Housing authority, the Public Roads administration and the Public Buildings administration) to form the Federal Works Agency. The consolidation into one agency was intended to achieve a close co-operation between work projects and contract public works which was first attempted in the works program of 1935. The Civilian Conservation corps and the National Youth administration which were included in the works program of 1935 were transferred to the Federal Security Agency under the 1939 reorganization. In the new Federal Works Agency, the WPA continued to operate work projects, taking its workers from the relief rolls, and providing the bulk of all federal emergency employment. (J. M. Cy.)

Food Stamp Plan.—Paralleling Swedish experiments in the use of surplus agricultural produce to feed needy persons, the federal government had contributed to general relief after 1936 by buying up surplus food directly from farmers, under certain conditions, and then distributing it to persons on relief of almost any kind, to schools for lunches for children, to workers on WPA or those certified for it, to those receiving old age assistance, aid to the blind, to parents of dependent children and to those on agricultural relief. Late in 1939 an ingenious scheme, both socially and economically sound, known as the Food Stamp plan, was substituted for this direct distribution, replacing these goods within the channels of trade. Each person or family certified as in need was given 50% additional allowance on his food budget in the form of stamps, which he might use to purchase certain designated articles of food at any food mart.

World War II and After.—As in many other departments of the government, the defense emergency in 1941 made profound changes in the work of the Federal Works Agency. Its largest component, the Work Projects administration, managed a diminishing program as millions of workers who had received public assistance returned to private employment, which was expanding under the impact of the defense program. The work relief program, which at the beginning of 1941 had employed 1,800,000 persons, employed only 1,000,000 at the year's end. In the Work Projects administration, as in other parts of the Federal Works Agency, emphasis shifted rapidly to programs directly related to the defense emergency, and nondefense activities were curtailed.

As projects of slum clearance and other peacetime projects declined, new activities were undertaken by the Federal Works Agency in the fields of defense housing, defense public works and defense highway construction. To assure homes for defense workers who had migrated to areas where shipping, aircraft, ordnance and other defense projects were in the making, congress enacted the Lanham act, Oct. 14, 1940, charging the Federal Works administrator with the responsibility of carrying out a housing program for defense industrial workers and for enlisted men in the army and the navy. By the end of 1941, the Federal Works administration was also empowered to aid in the construction of schools, hospitals, recreation centres, water systems and other community facilities such as child-care centres and nurseries for children of women war workers in overcrowded defense areas. The president also approved congressional authorization for the construction of access roads connecting new cantonments and industrial plants with the existing public roads system, and permitting the Public Roads administration to undertake much-needed work to strengthen the nation's highways. In the Work Projects administration many projects of direct value to U.S. national defense were undertaken, including the construction of new roads and airports and a variety of small undertakings.

After a year of U.S. participation in World War II, only 300,000 workers remained on the payrolls of WPA projects. At the suggestion of the Work Projects administration, Pres. Roosevelt issued an executive order in Dec. 1942 which provided for the termination of all work still in progress, by Feb. 1, 1943, or the earliest possible date thereafter. Employment on the projects

decreased throughout the year as the various units completed their work. In this last year of the WPA, its employees earned \$46,700,000, or just a little more than $\frac{1}{2}$ % of the \$1,800,000,000 earned in 1938, the year of highest benefits.

During 1942, the out-of-school work program of the National Youth administration was discontinued. Only the student work program then remained, and this too was abolished in June 1943. No congressional appropriations were made thereafter for NYA since employment openings for young people of college age were plentiful, and many of them were also being absorbed into the military services. During the first half of 1942, NYA disbursements were less than \$3,800,000 as against nearly \$27,000,000 expended in 1940.

As the war progressed, the national food economy was also reversed from one of surpluses to one of scarcity. On March 1, 1943, distributions of surplus commodities through the food stamp plan and direct channels were discontinued by order of the department of agriculture. Thus by the close of 1943, public relief was limited to state-federal aid to the aged, the blind, and dependent children, and the local-state channels of general assistance. In that year, the trend of full employment and reduced expenditures for public assistance was established which continued for the duration of World War II.

With the end of the war, however, this trend was reversed and while not particularly marked in the statistics of relief, signs were not wanting that applications for assistance might rise. A spot survey taken in Nov. 1945 of about 20 communities showed aged workers were losing their jobs to workers from war plants and to returned veterans; Negroes, who were drawn into industries during the period of manpower shortage were being dismissed and non-Negroes employed in their stead. Applications for unemployment compensation promptly reflected the cutbacks in war work, jumping from an average of less than 400,000 a week up to Aug. 15 to 1,700,000 in October.

In 1946-47, there were no major extensions of the programs of former years for the relief of the necessities of life, and no economic recessions creating new groups of needy persons. The wartime armies had been demobilized and the extensive provisions made to effect an easy transfer to occupations of peacetime proved substantially adequate.

RELIEF, in sculpture a term signifying ornament, a figure

ADAPTED FROM "U. S. BUREAU OF ECONOMIC ANALYSIS, 1943"
EXPENDITURES AND EARNINGS, U. S. FEDERAL WORK PROGRAM, 1933-43

or figures raised from the ground of a flat surface, of which the sculptured portion forms an inherent part of the body of the whole. The design may be in high relief—"alto-relievo" (*q.v.*), or low relief—"bas-relief" or "basso-relievo" (*q.v.*). The Egyptians merely sunk the outlines and barely suggested the modelling of the figures, which never projected beyond the face of the surrounding ground. The Persians, the Etruscans and the Greeks carried on the art to the highest perfection, alike in sculpture and architectural ornament, and they applied it to gem sculpture, as in the case of "cameo" (*q.v.*). Similarly, the inverse treatment of relief—that is, sunk *below* the surface, in order that when used for seals a true relief is obtained—was early brought to great completeness; this form of engraving is called "intaglio" (*q.v.*). The degree of projection in relief, broadly speaking, has varied greatly with the periods of art.

RELIGION AND THEOLOGY, ARTICLES ON. For the purpose of enumerating the main articles in this section, a division will be made into (1) Christian, and (2) Non-Christian.

(1) CHRISTIAN

The number of articles on the different aspects of Christian doctrine, faith and Church is so great that nothing beyond a casual selection of titles can be made here. Anything approaching a complete guide to the separate religious divisions would be a lengthy index of titles of differing merit. To begin with, all the prophets of the Old Testament, all the disciples of the New Testament, and all the books of the Bible have separate articles under their own headings. Special terms occurring in the Scriptures, such as ALPHA and OMEGA; ARMAGEDDON; APOSTLE; ANGEL, etc., have articles to themselves, where their meaning and connection with other passages in Holy Writ are given in some detail. The article BIBLE is divided, for convenience of reference, into sections and sub-sections, with appropriate subheads and side-heads to mark out the main points of interest. CONCORDANCE is exhaustively treated, and the article JESUS CHRIST deals with the life of the Founder of Christianity and all His activities and influences. JOSEPH (husband of Mary) and MARY (the Mother of Jesus), are important articles, and those such as APOCALYPSE and PASTORAL EPISTLES are deserving of attention. VULGATE; ATHEISM; DEISM; IMMORTALITY; MIRACLE; MYSTICISM; ESCHATOLOGY; APOLOGETICS; DOGMA, DOGMATIC THEOLOGY; ABSOLUTION; ANTICHRIST; APOSTASY; ATONEMENT; BAPTISM; BENEDICTION; CATECHISM; CATHOLIC; CHURCH; CONFESSION; CONFIRMATION; CREEDS; EXCOMMUNICATION; EXTREME UNCTION; FASTING; GRACE; MARTYR; PREACHING; RELICS; SACRAMENT; SIN and WORSHIP, are all important articles well worthy of special attention. The different sects and divisions of Christian practice and worship are treated under their own headings.

CHURCH HISTORY is a long article suitably sub-divided for convenience of reference. The different councils (e.g., BASEL, COUNCIL OF, etc.) are treated in separate articles apart from the main article COUNCIL. The synods, too, have special articles under the names they usually bear, as is also the case with the different courts. The famous heresies are also treated under their separate names. There is also a large article PAPACY.

The chief saints of the Church Calendar are noted and details are given under their respective names. The popes have biographies, and are also treated in connection with their special work in separate articles where there is historical mention of their times. The reader should refer to APOSTOLIC CONSTITUTIONS; APOSTOLIC CANONS; DIDACHE, THE, etc., for the Christian documents required.

There are comprehensive articles on the religious orders. (See for example, AMBROSIAIANS; BENEDICTINES; CAPUCHINS, etc.) In addition to the main article ROMAN CATHOLIC CHURCH, all important sub-divisions of this aspect of Christian worship have articles under their own headings, e.g., IMMACULATE CONCEPTION; INDULGENCE; PENANCE, etc. All the main Eastern Churches have articles devoted specially to them. All relationships of the Church of England and the modern Continental Churches, their special forms of worship and attitude to problems of belief and practice, are treated under their own headings. Ecclesiastical offices are

treated under separate headings, e.g., ABESS; ACOLYTE; ARCH-BISHOP; ARCHDEACON, etc. The ecclesiastical seasons have all their own headings, and this is also the case with Ecclesiology and its sub-divisions. Bible and Biblical Criticism is a section which contains important articles on the prophets and books of the Old Testament, and the Apostles and books of the New.

2. NON-CHRISTIAN

In this section appear such major articles as BABYLONIAN AND ASSYRIAN RELIGION; GREEK RELIGION; ROMAN RELIGION; HINDUISM; ANCESTOR-WORSHIP; ZOROASTER (or Zoroastrianism); ASCETICISM, etc. Apart from the main articles on Greek and Roman Religion, there are numerous short articles on the gods and goddesses of the ancient classical world. Such articles as ANIMISM; ANTHROPOMORPHISM; DEMONOLOGY; DIVINATION; EXORCISM; FETTERISM; DEAD, DISPOSAL OF THE; IDOLATRY; LYCANTHROPY; MYTHOLOGY; PRIEST; RITUAL and WITCHCRAFT are the main supports of the non-Christian religious programme.

In addition to these there are numerous accounts, each under its own heading, of the gods and spirits of Brahmanism, Buddhism, etc., and the early faiths of Scandinavia, Europe, and the two divisions of America.

RELIGION. The treatment of this subject will fall into two distinct sections, *A. Primitive Religion* and *B. The Higher Religions*.

A. PRIMITIVE RELIGION

I. Definition of Primitive Religion.—Amongst the numberless definitions of religion that have been suggested, those that have been most frequently adopted for working purposes by anthropologists are Tylor's and Frazer's. Sir E. B. Tylor in *Primitive Culture* (1), i. 424, proposes as a "minimum definition" of religion "the belief in spiritual beings." Objections to this definition on the score of incompleteness are, firstly, that, besides belief, practice must be reckoned with (since, as W. Robertson Smith has made clear in his *Lectures on the Religion of the Semites*, 1889, ritual is in fact primary for primitive religion, whilst dogma and myth are secondary); secondly, that the outlook of such belief and practice is not exclusively towards the spiritual, unless this term be widened until it mean next to nothing, but is likewise towards the quasi-material, as will be shown presently. The merit of this definition, on the other hand, lies in its bilateral form, which calls attention to the need of characterizing both the religious attitude and the religious object to which the former has reference. The same form appears in Sir J. G. Frazer's definition in *The Golden Bough* (3rd ed.), i. 222. He understands by religion "a propitiation or conciliation of powers superior to man which are believed to direct and control the course of nature and of human life." He goes on to explain that by "powers" he means "conscious or personal agents." It is also to be noted that he is here definitely opposing religion to magic, which he holds to be based on the (implicit) assumption "that the course of nature is determined, not by the passions or caprice of personal beings, but by the operation of immutable laws acting mechanically." His definition improves on Tylor's in so far as it makes worship integral to the religious attitude. By regarding the object of religion as necessarily personal, however, he is led to exclude much that the primitive man undoubtedly treats with awe and respect as exerting a mystic effect on his life. Further, in maintaining that the powers recognized by religion are always superior to man, he leaves unclassified a host of practices that display a bargaining, or even a hectoring, spirit on the part of those addressing them (see PRAYER). Threatening or beating a fetish cannot be brought under the head of magic, even if we adopt Frazer's principle (*op. cit.* i. 225) that to constrain or coerce a personal being is to treat him as an inanimate agent; for such a principle is quite inapplicable to cases of mere terrorism, whilst it may be doubted if it even renders the sense of the magician's typical notion of 'his mode of operation, viz., as the bringing to bear of a greater *mana* or psychic influence (see below) on what has less, and must therefore do as it is bidden. Such definitions, then, are to be accepted, if at all, as definitions

of type, selective designations of leading but not strictly universal features. An encyclopaedic account, however, should rest rather on an exterior definition which can serve as it were to pigeon-hole the whole mass of significant facts. Such an exterior definition is suggested by E. Crawley in *The Tree of Life*, 209, where he points out that "neither the Greek nor the Latin language has any comprehensive term for religion, except in the one *lepis* and in the other *sacra*, words which are equivalent to 'sacred.' No other term covers the whole of religious phenomena, and a survey of the complex details of various worships results in showing that no other conception will comprise the whole body of religious facts." It may be added that we have here no generalization imported from a higher level of culture, but an idea or blend of ideas familiar to primitive thought. An important consequence of this giving the study of primitive religion the wide scope of a comparative hierology is that magic is no longer divorced from religion, since the sacred will now be found to be coextensive with the magico-religious, that largely undifferentiated plasm out of which religion and magic slowly take separate shapes as society comes more and more to contrast legitimate with illicit modes of dealing with the sacred. We may define, then, the religious object as the sacred, and the corresponding religious attitude as consisting in such manifestation of feeling, thought and action in regard to the sacred as is held to conduce to the welfare of the community or to that of individuals considered as members of the community.

II. Aspects of the Nature of the Sacred.—To exhibit the general character of the sacred as it exists for primitive religion it is simplest to take stock of various aspects recognized by primitive thought as expressed in language. If some, and not the least essential, of these aspects are quasi-negative, it must be remembered that negations—witness the Unseen, the Unknown, the Infinite of a more advanced theology—are well adapted to supply that mystery on which the religious consciousness feeds with the slight basis of conceptual support it needs. (1) *The sacred as the forbidden.* The primitive notion that perhaps comes nearest to our "sacred," whilst it immediately underlies the meanings of the Latin *sacer* and *sacris*, is that of a *taboo*, a Polynesian term for which equivalents can be quoted from most savage vocabularies. The root idea seems to be that something is marked off as to be shunned, with the added hint of a mystic sanction or penalty enforcing the avoidance. Two derivative senses of a more positive import call for special notice. On the one hand, since that which is tabooed is held to punish the taboo-breaker by a sort of mystic infection, taboo comes to stand for uncleanness and sin. On the other hand, since the isolation of the sacred, even when originally conceived in the interest of the profane, may be interpreted as self-protection on the part of the sacred as against defiling contact, taboo takes on the connotation of ascetic virtue, purity, devotion, dignity and blessedness. Primary and secondary senses of the term between them cover so much ground that it is not surprising to find taboo used in Polynesia as a name for the whole system of religion, founded as it largely is on prohibitions and abstinences. (2) *The sacred as the mysterious.* Another quasi-negative notion of more restricted distribution is that of the mysterious or strange, as we have it expressed, for example, in the Siouan *wakan*, though possibly this is a derivative meaning. Meanwhile, it is certain that what is strange, new or portentous is regularly treated by all savages as sacred. (3) *The sacred as the secret.* The literal sense of the term *churinga*, applied by the Central Australians to their sacred objects, and likewise used more abstractly to denote mystic power, as when a man is said to be "full of *churinga*," is "secret," and is symptomatic of the esotericism that is a striking mark of Australian, and indeed of all primitive, religion, with its insistence on initiation, its exclusion of women, and its strictly enforced reticence concerning traditional lore and proceedings. (4) *The sacred as the potent.* Passing on to positive conceptions of the sacred, perhaps the most fundamental is that which identifies the efficacy of sacredness with such mystic or magical power as is signified by the *mana* of the Pacific or *orenda* of the Hurons, terms for which analogies are forthcoming on all

sides. Of *mana* R. H. Codrington in *The Melanesians*, 119 n., writes: "It essentially belongs to personal beings to originate it, though it may act through the medium of water, or a stone or a bone. All Melanesian religion consists . . . in getting this *mana* for oneself, or getting it used for one's benefit." E. Tregear's *Maori-Polynesian Comparative Dictionary* shows how the word and its derivatives are used to express thought, memory, emotion, desire, will—in short, psychic energy of all kinds. It also stands for the vehicle of the magician's energy—the spell; which would seem likewise to be a meaning, perhaps the root-meaning, of *orenda* (cf. J. N. B. Hewitt, *American Anthropologist*, N.S., iv, 40). Whereas everything, perhaps, has some share of indwelling potency, whatever is sacred manifests this potency in an extraordinary degree, as typically the wonder-working leader of society, whose *mana* consists in his cunning and luck together. Altogether, in *mana* we have what is *par excellence* the primitive religious idea in its positive aspect, taboo representing its negative side, since whatever has *mana* is taboo, and whatever is taboo has *mana*. (5) *The sacred as the animate*. The term "animism," which embodies Tylor's classical theory of primitive religion, is unfortunately somewhat ambiguous. If we take it strictly to mean the belief in ghosts or spirits having the "vaporous materiality" proper to the objects of dream or hallucination, it is certain that the agency of such phantasms is not the sole cause to which all mystic happenings are referred (though ghosts and spirits are everywhere believed in, and appear to be endowed with greater predominance as religious synthesis advances amongst primitive peoples). Thus there is good evidence to show that many of the early gods, notably those that are held to be especially well disposed to man, are conceived rather in the shape of magnified non-natural men dwelling somewhere apart, such as the Mungan-ngaur of the Kurnai of S.E. Australia (cf. A. Lang, *The Making of Religion*, x. seq.). Such anthropomorphism is with difficulty reduced to the Tylorian animism. The term, however, will have to be used still more vaguely, if it is to cover all attribution of personality, will or vitality. This can be more simply brought under the notion of *mana*. Meanwhile, since quasi-mechanical means are freely resorted to in dealing with the sacred, as when a Maori chief snuffs up the sanctity his fingers have acquired by touching his own sacred head that he may restore the virtue to the part whence it was taken (R. Taylor, *Te Ika a Māui*, 165), or when uncleanness is removed as if it were a physical secretion by washing, wiping and so forth, it is hard to say whether what we should now call a "material" nature is not ascribed to the sacred, more especially when its transmissibility after the manner of a contagion is the trait that holds the attention. It is possible, however, that the savage always distinguishes in a dim way between the material medium and the indwelling principle of vital energy, examples of a pure fetishism, in the sense of the cult of the purely material, recognized as such, being hard to find. (6) *The sacred as the ancient*. The prominence of the notion of the *Alcheringa* "dreamtime," or sacred past, in Central Australian religion illustrates the essential connection perceived by the savage to lie between the sacred and the traditional. Ritualistic conservatism may be instanced as a practical outcome of this feeling. Another development is ancestor-worship, the organized cult of ancestors marking, however, a certain stage of advance beyond the very primitive, though the dead are always sacred and have *mana* which the living may exploit for their own advantage.

III. *The Activity of the Sacred*.—The foregoing views of the sacred, though starting from distinct conceptions, converge in a single complex notion, as may be seen from the many-sided sense borne by such a term as *wakon*, which may stand not only for "mystery," but also for "power, sacred, ancient, grandeur, animate, immortal" (W. J. McGee, *15th Report of U. S. Bureau of Ethnology*, 182). The reason for this convergence is that, whereas there is found great difficulty in characterizing the elusive nature of the sacred, its mode of manifesting itself is recognized to be much the same in all its phases. Uniform characteristics are the fecundity, ambiguity, relativity and transmissibility of its activity. (1) *Fecundity*. The mystic potency of the sacred is

no fixed quantity, but is big with possibilities of all sorts. The same sacred person, object, act, will suffice for a variety of purposes. Even where a piece of sympathetic magic appears to promise definite results, or when a departmental god is recognized, there would seem to be room left for a more or less indefinite expectancy. It must be remembered that the meaning of a rite is for the most part obscure to the participants, being overlaid by its traditional character, which but guarantees a general efficacy. "Blessings come, evils go," may be said to be the magico-religious formula implicit in all socially approved dealings with the sacred, however specialized in semblance. (2) *Ambiguity*. Mystic potency, however, because of the very indefiniteness of its action, is a two-edged sword. The sacred is not to be approached lightly. It will heal or blast, according as it is handled with or without due circumspection. That which is taboo, for instance, the person of the king, or woman's blood, is poison or medicine according as it is manipulated, being inherently just a potentiality for wonder-working in any direction. Not but what primitive thought shows a tendency to mark off a certain kind of mystic power as wholly bad by a special name, e.g., the *arungquillo* of Central Australia; and here, we may note, we come nearest to a conception of magic as something other than religion, the trafficker in *arungquillo* being socially suspect, nay, liable to persecution, and even death (as amongst the Arunta tribe, see Spencer and Gillen, *The Arunta*, ii, 414 n.), at the hands of his fellows. On the other hand, wholly beneficent powers seem hardly to be recognized, unless we find them in beings such as Mungan-ngaur ("father-our"), who derive an ethical character from their association with the initiation ceremonies and the moral instruction given thereat (cf. Lang, l.c.). (3) *Relativity*. So far we have tended to represent the activity of the sacred as that of a universal force, somewhat in the style of our "electricity" or "mind." It remains to add that this activity manifests itself at numberless independent centres. These differ amongst themselves in the degree of their energy. One spell is stronger than another, one taboo more inviolable than another. W. H. R. Rivers (*The Todas*, 448) gives an interesting analysis of the grades of sanctity apparent in Toda religion. The gods of the hill-tops come first. The sacred buffaloes, their milk, their bells, the dairies and their vessels are on a lower plane; whilst we may note that there are several grades amongst the dairies, increase of sanctity going with elaboration of dairy ritual (cf. *ibid.* 332). Still lower is the dairyman, who is in no way divine, yet has sanctity as one who maintains a condition of ceremonial purity. (4) *Transmissibility*. If, however, this activity originates at certain centres, it tends to spread therefrom in all directions. F. B. Jevons (in *An Introduction to the History of Religion*, vii.) distinguishes between "things taboo," which have the mystic contagion inherent in them, and "things tabooed," to which the taboo-infection has been transmitted. In the former class he places supernatural beings (including men with *mana* as well as ghosts and spirits), blood, new-born children with their mothers, and corpses; which list might be considerably extended, for instance, by the inclusion of natural portents, and animals and plants such as are strikingly odd, dangerous or useful. Any one of these can pass on its sacred quality to other persons and objects (as a corpse defiles the mourner and his clothes), nay to actions, places and times as well (as a corpse will likewise cause work to be tabooed, ground to be set apart, a holy season to be observed). Such transmissibility is commonly explained by the association of ideas, that becoming sacred which as it were reminds one of the sacred; though it is important to add, firstly, that such association takes place under the influence of a selective interest generated by strong religious feeling, and, secondly, that this interest is primarily a collective product, being governed by a social tradition which causes certain possibilities of ideal combination alone to be realized, whilst it is the chief guarantee of the objectivity of what they suggest.

IV. *The Exploitation of the Sacred*. A. Methods.—It is hard to find terms general enough to cover dealings with the sacred that range from the manipulation of an almost inanimate type of power to intercourse modelled on that between man and man. Primitive religion, however, resorts to either way of ap-

proach so indifferently as to prove that there is little or no awareness of an inconsistency of attitude. The radical contrast between mechanical and spiritual religion, though fundamental for modern theology, is alien to the primitive point of view, and is therefore inappropriate to the purposes of anthropological description. (1) *Acquisition*. Mystic power may be regarded as innate so far as skill, luck or querness are signs and conditions of its presence. On the whole, however, savage society tends to regard it as something acquired, the product of acts and abstinences having a traditional character for imparting magico-religious virtue. An external symbol in the shape of a ceremony or cult-object is of great assistance to the dim eye of primitive faith. Again, the savage universe is no preserve of man, but is an open field wherein human and non-human activities of all sorts compete on more or less equal terms, yet so that a certain measure of predominance may be secured by a judicious combination of forces.

(2) *Concentration*. Hence the magico-religious society or individual practitioner piles ceremony on ceremony, name of power on name of power, relic on relic, to consolidate the forces within reach and assume direction thereof. The transmissibility of the sacred ensures the fusion of powers drawn from all sources, however disparate. (3) *Induction*. It is necessary, however, as it were, to bring this force to a head. This would appear to be the essential significance of sacrifice, where a number of sacred operations and instruments are made to discharge their efficacy into the victim as into a vat, so that a blessing-yielding, evil-neutralizing force of highest attainable potency is obtained (see H. Hubert and M. Mauss, 'Essai sur la nature et la fonction du sacrifice' in *L'Année sociologique*, ii.). (4) *Renovation*. An important motif in magico-religious ritual, which may not have been without effect on the development of sacrifice, is, as Frazer's main thesis in *The Golden Bough* asserts, the imparting of reproductive energy to animals, plants and man himself, its cessation being suggested by such phenomena as old age and the fall of the year. To concentrate, induce and renovate are, however, but aspects of one process of acquisition by the transfusion of a transmissible energy.

(5) *Demission*. Hubert and Mauss show in their penetrating analysis of sacrifice that after the rite has been brought to its culminating point there follows as a pendant a ceremony of re-entry into ordinary life, the idea of which is preserved in the Christian formula *Ite, missa est*. (6) *Insulation*. Such deposition of sacredness is but an aspect of the wider method that causes a ring-fence to be erected round the sacred to ward off casual trespassers at once in their own interest and to prevent contamination. We see here a natural outcome of religious awe supported by the spirit of esotericism, and by a sense of the need for an expert handling of that which is so potent for good or ill.

(7) *Direction*. This last consideration brings to notice the fact that throughout magico-religious practice of all kinds the human operator retains a certain control over the issue. In the numberless transitions that, whilst connecting, separate the spell and the prayer we observe as the accompaniment of every mood from extreme imperiousness to extreme humility an abiding will and desire to help the action out. Even 'Thy will be done' preserves the echo of a direction, and, needless to say, this is hardly a form of primitive address. At the bottom is the vague feeling that it is man's own self-directed mysterious energy that is at work, however much it needs to be reinforced from without. Meanwhile, tradition strictly prescribes the ways and means of such reinforcement, so that religion becomes largely a matter of sacred lore; and the expert director of rites, who is likewise usually at this stage the leader of society, comes more and more to be needed as an intermediary between the lay portion of the community and the sacred powers.

V. Results.—Hitherto our account of primitive religion has had to move on somewhat abstract lines. His religion is, however, anything but an abstraction to the savage, and stands rather for the whole of his concrete life so far as it is penetrated by a spirit of earnest endeavour. The end and result of primitive religion is, in a word, the consecration of life, the stimulation of the will to live and to do. This bracing of the vital feeling takes place by means of imaginative appeal to the great forces man perceives

stirring within him and about him, such appeal proving effective doubtless by reason of the psychological law that to conceive strongly is to imitate. Meanwhile, security against any clashing of conceptions to inhibit the tendency of the idea of an acquired "grace" to realize itself in action, is assured by the complete unanimity of public opinion, dominated as it is by an inveterate custom. To appreciate the consecrating effect of religion on primitive life we have only to look to the *churinga*-worship of the Central Australians (as described by Spencer and Gillen in *The Native Tribes of Central Australia*, [1] *The Northern Tribes of Central Australia and The Arunta*). Contact with these repositories of mystic influence "makes them glad" (*Nat. Tr.* 165); it likewise makes them "good," so that they are no longer greedy or selfish (*North. Tr.* 266); it endows them with second sight (*ibid.*); it gives them confidence and success in war (*Nat. Tr.* 135); in fact, there is no end to its "strengthening" effects (*ibid.* n.). Or, again, we may note the earnestness and solemnity that characterize all their sacred ceremonies. The inwardness of primitive religion is, however, non-existent for those who observe it as uninitiated strangers; whilst, again, it evaporates as soon as native custom breaks down under pressure of civilization, when only fragments of meaningless superstition survive: for which reason travesties of primitive religion abound.

It remains to consider shortly the consecration of life in relation to particular categories and departments. (1) *Education*. Almost every tribe has its initiation ceremonies, and in many tribes adult life may almost be described as a continuous initiation. The object of these rites is primarily to impart mystic virtue to the novice, such virtue, in the eyes of the primitive man, being always something more than social usefulness, amounting as it does to a share in the tribal luck by means of association with all it holds sacred. Incidentally the candidate is trained to perform his duties as a tribesman, but religion presides over the course, demanding earnest endeavour of an impressionable age. (2) *Government*. Where society is most primitive it is most democratic, as in Australia, and magico-religious powers are possessed by the whole body of fully initiated males, age, however, conferring increase of sacred lore and consequently of authority; whilst even at this stage the experts tend to form an inner circle of rulers. The man with *mana* is bound to come to the top, both because his gifts give him a start and because his success is taken as a sign that he has the gift. A decisive "moment" in the evolution of chiefship is the recognition of hereditary *mana*, bound up as this is with the handing on of ceremonies and cult-objects. Invested, as society grows more complex, with a sanctity increasingly superior to that of the layman, the priest-king becomes the representative of the community as repository of its luck, whilst, as controller of all sacred forces that bear thereon, he is, as Frazer puts it, "dynamical centre of the universe" (*The Golden Bough* [3rd ed.], iii. 1). Only when the holy man's duty to preserve his holiness binds him hand and foot in a network of taboos does his temporal power tend to devolve on a deputy. (3) *Food-supply*. In accordance with the principle of Renovation (see above), the root-idea of the application of religion to economics is not the extorting of boons from an unwilling nature, but rather the stimulation of the sources of life, so that all things alike may increase and multiply. (4) *Food-taking*. Meanwhile, the primitive meal is always more or less of a sacrament, and there are many food-taboos, the significance of which is, however, not so much that certain foods are unclean and poisonous as that they are of special virtue and must be partaken of solemnly and with circumspection. (5) *Kinship*. It is hard to say whether the unit of primitive society is the tribe or the group of kinsmen. Both are forms of union that are consolidated by means of religious usages. Thus in Australia the initiation ceremonies, concerned as they partly are with marriage, always an affair between the kin-groups, are tribal, whilst the totemic rites are the prime concern of the members of the totem clans. The significance of a common name and a common blood is immensely enhanced by its association with mystic rights and duties, and the pulse of brotherhood heats faster. (6) *The Family*. Side by side with the kin there is always found the domestic group, but the latter

institution develops fully only as the former weakens, so that the one comes largely to inherit the functions of the other, whilst the tribe too in its turn hands over certain interests. Thus in process of time birth-rites, marriage-rites, funeral-rites, not to mention subordinate ceremonies such as those of name-giving and food-taking, become domestic sacraments. (7) *Sex*. Woman, for certain physiological reasons, is always for primitive peoples hedged round with sanctity, whilst man does all he can to inspire awe of his powers in woman by keeping religion largely in his own hands. The result, so far as woman is concerned, is that, in company with those males who are endowed with sacredness in a more than ordinary degree, she tends as a sex to lose in freedom as much as she gains in respect. (8) *Personality*. Every one has his modicum of innate *mana*, or at least may develop it in himself by communicating with powers that can be brought into answering relation by the proper means. Nagualism, or the acquisition of a mystic guardian, is a widely distributed custom, the essence of which probably consists in the procuring of a personal name having potency. The exceptional man is recognized as having *mana* in a special degree, and a belief thus held at once by others and by himself is bound to stimulate his individuality. The primitive community is not so custom-bound that personality has no chance to make itself felt, and the leader of men possessed of an inner fund of inspiration is the wonder-worker who encourages all forms of social advance.

VI. *Psychology of the Primitive Attitude Towards the Sacred*.—We are on firmer ground when simply describing the phenomena of primitive religion than when seeking to account for these in terms of natural law—in whatever sense the conception of natural law be applicable to the facts of the mental life of man. One thing is certain, namely, that savages stand on virtually one footing with the civilized as regards the type of explanation appropriate to their beliefs and practices. We have no right to refer to "instincts" in the case of primitive man, any more at any rate than we have in our own case. A child of civilized parents brought up from the first amongst savages is a savage, neither more nor less. Though race may count for something in the matter of mental effectiveness—and at least it would seem to involve differences in weight of brain—it clearly counts for much less than does *milieu*, to wit, that social environment of ideas and institutions which depends so largely for its effectiveness on mechanical means of tradition, such as the art of writing. The outstanding feature of the mental life of savages known to psychologists as "primitive credulity" is doubtless chiefly due to sheer want of diversity of suggestiveness in their intellectual surroundings. Their notions stick fast because there are no competing notions to dislodge them. Society suffers a sort of perpetual obsession, and remains self-hypnotized as it were within a magic circle of traditional views. A rigid orthodoxy is sustained by means of purblind imitation assisted by no little persecution. Such changes as occur come about, not in consequence of a new direction taken by conscious policy, but rather in the way that fashions in dress alter amongst ourselves, by subconscious, hardly purposive drifting. The crowd rather than the individual is the thinking unit. A proof is the mysterious rapid extinction of savages the moment that their group-life is broken up; they are individually so many lost sheep, without self-reliance or initiative. And the thinking power of a crowd—that is, a mob, not a deliberative assembly—is of a very low order, emotion of a "panicky" type driving it hither and thither like a rudderless ship. However, as the students of mob-psychology have shown, every crowd tends to have its *meneur*, its mob-leader, the man who sets the cheering or starts the running-away. So too, then, with the primitive society. Grossly ignorant of all that falls outside "the daily round, the common task," they are full of panicky fears in regard to this unknown, and the primary attitude of society towards it is sheer avoidance, taboo. But the mysterious has another face. To the mob the mob-leader is mysterious in his power of bringing luck and salvation; to himself also he is a wonder, since he wills, and lo! things happen accordingly. He has *mana*, power, and by means of this *mana*, felt inwardly by himself, acknowledged by his fellows, he stems the social impulse

to run away from a mystery. Not without nervous dread—witness the special taboo to which the leader of society is subject—he draws near and strives to constrain, conciliate or cajole the awful forces with which the life of the group is set about. He enters the Holy of Holies; the rest remain without, and are more than half afraid of their mediator. In short, from the standpoint of lay society, the manipulator of the sacred is himself sacred, and shares in all the associations of sacredness. An anthropomorphism which is specifically a "magomorphism" renders the sacred powers increasingly one with the governing element in society, and religion assumes an ethico-political character, whilst correspondingly authority and law are invested with a deeper meaning.

VII. *The Abuse of the Sacred*.—Lest our picture of primitive religion appear too brightly coloured, a word must be said on the perversions to which the exploitation of the sacred is liable. Envy, malice and uncharitableness are found in primitive society, as elsewhere, and on their behalf the mystic forces are not infrequently unloosed by those who know how to do so. To use the sacred to the detriment of the community, as does, for instance, the expert who casts a spell, or utters a prayer, to his neighbour's hurt, is what primitive society understands by magic (*cf. arumgulla*, above), and anthropology has no business to attach any other meaning to the word if it undertakes to interpret the primitive point of view. On the other hand, if those in authority perpetrate in the name of what their society holds sacred, and therefore with its full approval, acts that to the modern mind are cruel, silly or revolting, it is bad science and bad ethics to speak of vice and degradation, unless it can be shown that the community in which these things occur is thereby brought nearer to elimination in the struggle for existence. As a matter of fact, the earlier and more democratic types of primitive society, uncontaminated by our civilization, do not present many features to which the modern conscience can take exception, but display rather the edifying spectacle of religious brotherhoods encouraging themselves by mystical communion to common effort. With the evolution of rank, however, and the concentration of magico-religious power in the hands of certain orders, there is less solidarity and more individualism, or at all events more opportunity for sectional interests to be pursued at other than critical times; whereupon fraud and violence are apt to infect religion. Indeed, as the history of the higher religions shows, religion tends in the end to break away from secular government with its aristocratic traditions, and to revert to the more democratic spirit of the primitive age, having by now obtained a clearer consciousness of its purpose, yet nevertheless clinging to the inveterate forms of human ritual as still adequate to symbolize the consecration of life—the quickening of the will to face life earnestly.

BIBLIOGRAPHY.—The number of works dealing with primitive religion is endless. The English reader who is more or less new to the subject is recommended to begin with Sir E. B. Tylor, *Primitive Culture* (4th ed., Lond. 1903), and then to proceed to Sir J. G. Frazer, *The Golden Bough* (3rd ed., Lond. 1912-15), together with his other works *The Belief in Immortality* 1913; *Folk-Lore in the Old Testament*, 1919; *The Worship of Nature*, 1926. Only second in importance to the above are W. Robertson Smith, *Lectures on the Religion of the Semites* (2nd ed. with introd. and additional notes by Dr. S. A. Cook, Lond. 1927); A. Lang, *Myth, Ritual and Religion* (2nd ed., Lond. 1899), and *Magic and Religion* (Lond. 1902); E. S. Hartland, *The Legend of Perseus* (Lond. 1894-96); F. B. Jevons, *An Introduction to the History of Religion* (2nd ed., 1903); E. Crawley, *The Tree of Life and The Mystic Rose* (2nd ed. Lond. 1927). The two last-mentioned works perhaps most nearly represent the views taken in the text, which are also developed by the present writer in *The Threshold of Religion* (2nd ed. 1909) and *Psychology and Folk-Lore*, 1920. See also H. Hubert and M. Mauss, "Essai sur la nature et la fonction du sacrifice," *L'Année sociologique*, ii.; and "Esquisse d'une théorie générale de la magie," *Ibid.* vii.; E. Durkheim, *Les formes élémentaires de la vie religieuse*, Paris, 1912; L. Levy-Bruhl, *Les fonctions mentales dans les sociétés inférieures*, Paris, 1912; R. H. Lowie, *Primitive Religion*, 1925; E. Westermarck, *Ritual and Belief in Morocco*, 1926; R. Briffault, *The Mothers*, 1927.

Side by side with works of general theory, first-hand authorities should be freely used. To make a selection from these is not easy, but the following at least are very important: R. H. Codrington, *The Melanesians* (Oxford, 1891); W. B. Spencer and F. J. Gillen, *The*

Native Tribes of Central Australia (Lond. 1899); *The Northern Tribes of Central Australia* (Lond. 1904); *The Arunta* (Lond. 1927); A. W. Howitt, *The Native Tribes of South-Eastern Australia* (Lond. 1904); A. C. Haddon, *Reports of the Cambridge Anthropological Expedition to Torres Straits* (Cambridge, 1904, vol. v.); A. B. Ellis, *The Tshi-Speaking Peoples of the Gold Coast* (Lond. 1897); *The Ewe-Speaking Peoples of the Slave Coast* (Lond. 1890); *The Yoruba-Speaking Peoples of the Slave Coast* (Lond. 1894); Miss M. H. Kingsley, *Travels in West Africa* (Lond. 1898), and *West African Studies* (Lond. 1899); R. S. Rattray, *Ashanti* (1923); *Religion and Art in Ashanti* (1927); E. Westermarck, *Ritual and Belief in Morocco* (1926); A. C. Ellis, *The Mosaic* (1905); W. Crooke, *The North-West Provinces of India* (Lond. 1897); W. H. R. Rivers, *The Todas* (1906). An immense amount of valuable evidence is to be obtained in the *Reports of the Bureau of Ethnology*, Smithsonian Institution, Washington. See Nos. 2, 5, 6, 7, 8, 9, 11, 13, 14, 15, 16, 18, 19, 21, 22, 23, and specially J. O. Dorsey, *A Study of Siouan Cults*, in No. 11; A. C. Fletcher, *The Hako*, in No. 21; and M. C. Stevenson, *The Zuni Indians*, in No. 23. Though dealing primarily with a more advanced culture, J. J. M. de Groot, *The Religious System of China* (1892-1901), will be found to throw much light on primitive ideas. Finally let it be repeated that there is offered here no more than an introductory course of standard authorities suitable for the English reader. (R. R. M.)

B. THE HIGHER RELIGIONS

No attempt can here be made to deal in detail with the Higher Religions. These are treated elsewhere under their respective headings. The different Higher Religions will only be considered in so far as they exhibit general principles. The main object of this section will be to show the lines on which the higher religious consciousness has developed, the broad features which it discloses, and the way in which it gives expression to human needs.

I. THE BASIS OF HIGHER RELIGION

Higher religions have developed on a pre-existing basis, in response to an impulse of the religious spirit seeking better self-expression. They have grown out of primitive religion, and all of them exhibit traces of their lineage. The survival of primitive traits in developed religion is a recurring phenomenon.

Evidently a higher religion can only emerge from a lower by a process of selection and development. Certain elements in early religion were intractable to development, while others were capable of it. To the former must be reckoned the strongly local character and particularist tendency of primitive religion. Spirits or powers attached to a definite spot, or embodied in a specific object are not easily elevated or expanded. Sentiment is conservative, and the being revered is too much lacking in individual quality to be readily transformed into a personal god. On the other hand, though the feeling of the clan that its objects of worship belong to it resists absorption in a larger cult, the strong sense of affinity with divine powers is capable of being elevated to a higher religious relationship. The same holds of primitive rites of communion. So too primitive ideas of Tabu and Interdiction have naturally passed into conceptions of the sacred and not-sacred, the pure and the impure, ideas that play a great part in developed religion. Again the cult of the dead, passing into that of family ancestors (see ANCESTOR-WORSHIP) easily expands with the enlargement of society: it has contributed important elements to national religion as in the case of China and ancient Rome. There are then higher possibilities in primitive religion, but they can only come to fruition with the emergence of new needs and a wider outlook.

II. THE RISE AND GROWTH OF POLYTHEISM

Higher religions emerge after the tribal has been superseded by the national culture. The transition to the more developed stage was the outcome of social changes which were reflected in the growth of man's inner life. This enrichment of personal life carried with it the need of a revised idea of the objects of worship and of the religious relation. The old spiritism, with its multitude of indefinite powers and capricious daemons, no longer corresponded to man's better ordered life and his varied and specialized interests. The larger and more constant values of a social order based on agriculture required divine beings capable of responding to its wants, and the rise of polytheism was the answer to these religious demands. The polytheistic system was the ex-

pression of man's vision of the world, a world of diverse departments and manifestations though not a real unity. But polytheism marks an advance. For it helped (a) to liberate religion from its bondage to purely local associations. And (b), it replaced the colourless powers or *numina* of older belief by a number of divine beings of more specific character and with more or less definite spheres of activity. A god, as distinguished from a spirit, is a being with determinate qualities which embody the values of which men are conscious.

(1) *The Emergence of Gods*.—The formless spirits supply only a shifting and uncertain basis on which to evolve a god. It has been suggested that the Greek deities Hermes and Artemis were developed in this way, and the Roman goddess Juno has been conceived as the general personification of the fertility *numen* or Juno of every woman. In any case such a process is infrequent. And the instances in which a totem has grown into a god, if they do occur at all, are extremely rare. What is clear is, that many of the greater gods have a connection with the phenomena of nature, and show traces of this relationship. Sometimes the connection is quite definite. Thus the Egyptian Ra and the Babylonian Shamash are sun-gods. The Greek Zeus, to whom corresponds the Vedic Dyauṣ, is a sky-god, and Ushas of the Vedic Hymns is a dawn-goddess. But there are many instances where the connection of a deity with nature cannot be precisely stated, though the general fact is not in doubt. Thus it remains uncertain what the natural basis of the Egyptian Osiris is; and we cannot say more of the Vedic Varuna and Vishnu than that they are connected with light and the heaven. The later development of a deity usually furnishes a very slender clue to his real origin. Moreover when the identification of a deity with a phenomenon of nature is transparent and precise, it is difficult for the god to develop by assuming new and higher qualities.

But while the greater phenomena of nature, by the fact that they possess a kind of physical universality, were a means of helping the mind to rise to the conception of deities of wider range and power, all gods are not to be explained thus. For some of them have their origin in the cult. The Hindu Soma is the power of the sacrificial libation, and Brahma the power of the sacrificial prayer personified. The Greek Hestia and the Roman Vesta (*q.v.*) have grown out of the sacred hearth as the centre of family life. Again, aspects of the cultural life, such as war and agriculture, have suggested deities who preside over them. In some cases men remarkable for their power and deeds have been exalted to the rank of divine, or semi-divine beings, e.g., the Greek Herakles and Asklepios. (See AEscULAPIUS and HERCULES.) The motives which develop polytheism are complex.

(2) *The Characterization of the Gods*.—As social life expands, its values become more varied, and the representations of the gods gain correspondingly in content. A god takes on new qualities and aspects in response to the needs and desires of his worshippers, and this process appears in all religions. Few gods have acquired so varied qualities and offices as the Greek Apollo. His identification with the sun is comparatively late, and his original character obscure. But he came to figure as the lord of flocks and herds, the master of oracles and prophecy, the god of healing, of purification, and of poetry. The imaginative process which predicated diversified attributes to a deity at the same time expressed the interests and aspirations of his worshippers. And the cultus was the chief medium by which these tendencies were developed and took concrete form.

The problem of organization is urgent where a religion arises out of the fusion of different cultures. Conspicuous instances are Babylonian and Greek religion. The Semitic invaders of Babylonia absorbed the older Sumerian culture, and found a place for Sumerian deities within their own pantheon. Greek civilization, as we now know, was the result of a fusion of two races, a race of Aryan invaders with the "Helladic" race. And it is almost certain that some of the Hellenic deities, e.g. Athene, Artemis, and Aphrodite, were adopted by the Greeks from the older culture. Yet it is always hard to achieve organization in the religious complex of polytheism even when a fusion of cultures seems to render it essential. The local associations and the cult-interests of the dei-

ties of the conquered race resist absorption. This difficulty may be overcome by fitting them into the enlarged pantheon as sons or servants of greater gods. Even then the older cults and beliefs will linger on. Homeric religion is no doubt an example of organisation; but it is artificial and literary, it does not fairly represent the actual beliefs and cult-practices in Greece. Still, however imperfectly the process may work itself out, there is behind polytheistic religion an impulse towards order and system. The development of social life, with its well-marked departments and functions, prompted the mind to conceive the divine world after the pattern of the human. The needs of worship, where not dominated by magical ideas, led in the same direction. For worship at the higher level cannot be easily apportioned among a number of divine beings whose mutual relations are quite indefinite. Some order and gradation are necessary.

III. THE CULTUS IN HIGHER RELIGIONS

The cultus is the focus of a religion; here it is concentrated and symbolized. As the focus of religious life the cultus becomes the point at which the sense of the sacred is most concentrated and intense. Radiating from this centre the sacred suffuses associated elements, investing with religious significance things and persons, places and times.

(1) *The Sacred Place*.—In early religion a place or thing became sacred through the presence in it of a spirit or power: *numen inest*. But when men began to build houses, when the house became the centre of family life, the thought lay to hand that there must be a house for the deity to be the focus of his worship. So the temple arose, reared often on sacred spots or "high places," hallowed by immemorial associations. As the deity was supposed to be more intimately present in his temple, it often became a centre of oracles and prophecy.

(2) *Sacred Men: the Priesthood*.—To holy places correspond holy men. The priest has his precursor in the wizard of the lower culture. The priest is a man endowed with a special knowledge of the cultus, is possessed of ritual purity, and embodies in his person the power of the sacred. At first priestly functions were not the exclusive privilege of a class. The head of the family, or the king as head of the people, offers sacrifice, so in the old Hebrew and Roman religions. But with the growing value attached to sacred functions there was the tendency to assign the priestly office to a particular class, as in the Hebrew, Persian and Hindu religions. Nowhere have the priests formed a more strict and exclusive caste than in Brahmanism.

(a) *Prayer*.—Perhaps nowhere does the spirit of a religion reveal itself more intimately than in its prayers. Yet even in the higher religions the idea of prayer as the free outpouring of the soul to the divine comes late. Primitive prayer is closely allied to the spell, and it must take a fixed form of words to be effective. The elevation of prayer comes with the development of inner life and an enhanced sense of ethical and spiritual values. Some knowledge of the kind of prayers offered in the cultus may be gathered from liturgical forms, e.g. from the sacrificial hymns of the Gathas and the Vedas. Prayer as petition to the gods is universal. But only in a few religions do we find prayers containing confessions of sin e.g. in the penitential psalms of the Hebrew and the Babylonian religions. Nowhere is the mysterious potency of prayer so exalted as in Brahmanism. Here prayer becomes a cosmic power which constrains the gods, and is finally construed as the divine principle of things. But wherever prayer ceases to be the expression of a fundamental dependence on the Divine, it loses its essential meaning and value. An intrinsically efficacious form of words is really a reversion to the magic spell. (See PRAYER.)

(b) *Sacrifice*.—Sacrifice springs from a deep-rooted impulse of the religious nature. It plays a part in early religion, and is present in some form in all the higher religions. The purpose of sacrifice is to maintain and strengthen, or to restore, fellowship with divine powers, and it takes a central place in the cultus. In the burnt-offering the sacrifice is wafted to the gods. In the bloody offering the victim, through contact with the altar, becomes charged with the sacred, and its sprinkled blood has aton-

ing virtue. The idea of substitutionary atonement is later and is due to reflection. In sacrifices of purification and atonement there is an ethical element which may lead to the higher development of religion. Just as with prayer, however, sacrifice may evolve in a way which is detrimental to the religious relation. What lifts sacrifice to an ethical and spiritual level is the conception of the righteousness of God. Where this obtains it is the inner side of the sacrificial act which is emphasised, the offering of the contrite heart and the obedient will. (See SACRIFICE.)

IV. RELIGIONS OF OBSERVANCE AND PROPHECIC RELIGIONS

The ritual aspect of religion tends to grow with the increasing complexity of the social order. When this tendency prevails religion takes on the specific character of legal observance.

(1) *Religions of Observance and Law*.—The idea of fixed observances or rules binding on the faithful develops where the idea of ritual purity is emphasised. The roots of the conception of the clean and unclean go back to primitive ideas of the sacred and of the dangerous with the associated apotropaic rites of expulsion. The growth of a sacrificial system leads to the fuller definition of the clean and unclean, and rules and forms are prescribed to preserve purity and remove impurity. In many higher religions there are detailed methods and a ritual of cleansing. In Roman religion we have lustration, which combined cathartic and apotropaic rites, and in Greece cathartic rites were specially connected with Apollo, the god of ritual purity. It is, however, in later Persian religion that rites of purification receive the most comprehensive and detailed expression, and nowhere is the notion of purity so dominant and pervasive. To all the numerous defilements that are possible correspond stated cleansings, and the Vendidad itself has been described as a kind of sin-codex. With this we may compare the laws of purity and impurity in the book of Leviticus, a book which embodies the cathartic ritual of post-Exilic Judaism. When a higher religion has developed a complicated system of ritual observance it brings the sense of the sacred into close and constant relation with the varied details of life. On the other hand, the religion itself is exposed to great dangers. The magical beliefs, which are a heritage of older religion, always tend to reassert themselves, and the religious rites readily degenerate to a mechanical performance which has intrinsic efficacy. When this happens the way to spiritual development is closed, and the later Persian and Jewish religions did not wholly escape the danger.

(2) *Prophectic Religion*.—Religion as piety has its centre within. The prophetic spirit proclaims this principle, and is itself the issue of personal and moral conviction. The prophet turns from the formal and external side of religion to emphasise its inner life, and when such a movement appears within a national religion it involves a loosening of religion from the social and political system. Great religious reforms and renewals arise from an individual or individuals for whom religion has become an intense and personal concern. Such a prophetic figure was Zarathustra. As we picture him from the Gathas he was a man of burning conviction, for whom Ahura Mazda was a supreme and moral deity whose cause is the right as against the lie. In this conflict the prophet calls men to fight and freely to choose the good. A like intense moral conviction and faith in the righteousness of Jahveh appears in the eighth century prophets of Israel linked with an even greater stress on the inner side of piety. The same note recurs in the teaching of Jesus that the vision of God is for the pure in heart.

It is curious to find an emphasis on the inner side of religion appearing within Hinduism. It emerges in the doctrine of Bhakti which has its classical expression in the *Bhagavad Gita*. Here we have the doctrine that trust and devotion, faith and love, to the divine power are a means of salvation. Religion assumes a personal colour. With Buddha this principle appears in the form of an extreme subjectivism. Within man himself lies the secret of salvation.

The work of the prophetic spirit makes possible the high stages of spiritual religion. Apart from its vivifying influence institu-

tional religion tends to grow formal and fixed, and its inner life to ebb. "Where there is no vision the people perish." The uprisings of the prophet is a token that a religion which seems dead has still within it the springs of life.

V. REDEEMPTIVE RELIGIONS

The prophetic movement is one symptom of the enhanced sense of personal and religious values, and the emergence of religions of salvation or redemption is another. Both indicate a slackening of the tie which binds religion to the national and political structure. For the official religion which men share simply as citizens of the state, a religion concerned with external observance rather than inner spirit and motives, no longer satisfies the more personal needs of which men are becoming aware. Corresponding to this increasing self-consciousness there grows up a craving for a more intimate and individual relation with the divine Power, a craving which the traditional religious forms cannot meet. And this feeling is deepened by the personal sense of the evils and sufferings of life. This longing for deliverance finds no fulfillment in the customary and external religion that a man inherits from his social group. Some better way is necessary; and the personal consciousness of the need of salvation carries with it a sense of responsibility for realizing it. So men seek some mode of expressing the religious spirit which shall embody their choice and preference, for religion must be in a more intimate sense their own. As the new movement takes its rise from broadly human needs, the form of religion which meets these needs cannot be merely local and particular: in its meaning at least it will be universal. This implies that the form of the religious relation is reconstituted, and this carries with it a differentiation of the religious community from political society. There now come into being religious associations or churches, where membership is based on a voluntary adherence to a particular religion or cult. This principle of a sacred society or church, clearly distinguished from secular society, is of great significance in the evolution of religion. For only under such conditions can the other-worldly or transcendent element in faith come to its due, and religion itself be delivered from bondage to political and secular interests. The idea of the sacred gains spiritual significance: the sacred community is united not merely in the observance of sacred rites but by a common disposition of the mind and will toward a religious good. And this good is not mundane but supramundane.

The new tendency finds expression in different ways. It appears as a movement which, without deliberately breaking with existing religion, takes form in religious associations which minister to felt religious wants. Again it appears as a philosophic gospel which offers spiritual deliverance to elect souls. Finally it manifests itself in the birth of a new religion, a religion which originates with a personal founder who proclaims a message of salvation. To the first class belong the various forms of mystery religions which were common in Greek and Mediterranean lands for a period of eight centuries B.C. One of the best known is the Orphic mysteries, a cult open at least to all Hellenes who underwent initiation. This cult held out the prospect of immortality and union with the divine. The body was a kind of tomb (*σῶμα*, *σῶμα*) from which the soul had to win deliverance. The way of salvation was by purification, abstinence and sacramental rites. The idea of something peculiarly sacred, in which the initiated participate, is common to mystery religions. The later mystery cults, like those of Attis, Isis and Mithras, which were widespread in eastern Mediterranean lands in the post-Alexandrian period, set in the foreground the spectacle of the dying and reviving god. Their votaries, through baptism, purification and a sacramental meal, somehow shared in the being of the god and with him rose to new life.

In the philosophic sphere, Neoplatonism proclaims the deliverance of the soul through an ecstatic union with the One that transcends rational thinking. Philosophic Brahmanism likewise has a doctrine of salvation, but a salvation through knowledge of the identity of the self with the Absolute or Brahman.

In Buddhism and in Christianity the spirit of redemptive reli-

gion is most fully expressed. In Buddhism the principle is seen taking an extreme subjective form. Buddha discards the metaphysics of Brahmanism, though he shares with it the idea that salvation comes through knowledge. The Enlightened, the Arahant, knows that thirst, with its attendant desire and suffering, is the evil of life, and by following the Noble Eightfold Way he advances to that indefinable goal, Nirvana. Redemption is thus a negative process: it is a gospel for the monk who breaks with the world rather than for the ordinary man who has to live in the world. Christian redemption is a richer and more positive conception. The deliverance sought is from moral evil or sin, and it is conditioned by repentance and faith. The end is not the extinction of personality but its enrichment through the power of a divine life, and it has corporate expression in life in the Kingdom of God which overcomes the evil in the world. Christian redemption is marked by its theistic basis, its sense of personal values and its positive character. The religious society of Buddhism is a monistic community: that of Christianity is the church, or the fellowship of the faithful united in the service of God.

VI. PANTHEISM, MYSTICISM AND MONOTHEISM

These are features found only in the higher religious culture. They all claim to be an advance on some existing religious system.

(1) Pantheism.

Pantheism is in the main a result of the development of reflective thinking. In the many it finds merely the passing appearances of the One. If pantheism is a late development, it was at least foreshadowed at earlier stages of religious evolution. Men soon became dimly conscious of a unity pervading the cosmic order and everywhere operative throughout it. In the Hindu conception of Rita and of Karma we have the idea of a power behind all things working by inflexible law. The ancient Chinese Tao conveys a sense of the eternal order and way of the universe. The Greek Moira and the Persian Asha contain the same ideas. This belief in a universal principle, when applied to polytheism, leads to the notion of a common power behind the gods and suggests that the various gods are only forms of the one Reality. Thus during the middle kingdom in Egypt reflective thinking treated the various gods as manifestations of Ra, and among the priesthood there was an esoteric pantheism.

The trend toward pantheism works itself out more readily when the gods are not sharply defined in their specific character and attributes. This was the case with the Vedic gods, since the qualities of one were often transferred to another. In the avatars of Vishnu one god assumes many divine forms. So by an easy process of transition the pantheism of the Upanishads and the Vedanta is reached. Here pantheism is thoroughgoing. All cosmic and psychical phenomena are unified in the one real Being: Brahman-Atman, the soul and the Absolute, are identical. *Tat tvam asi*: "that art thou." The multiplicity of the phenomenal world is only Maya or illusion; it disappears with knowledge. In contrast the clear-cut gods of Greece resisted a process of fusion. The Stoic pantheism, which identified Zeus with the universal and immanent reason or Logos, was rather an independent speculative theory than a development of Greek religion.

Religious pantheism is in the main a reflective development resulting from rational demands. If consistent, it is not a working religious creed, for it abolishes the religious relation by reducing it to an identity. (See PANTHEISM.)

(2) Mysticism.

Mysticism, like pantheism, in the strict sense is a phenomenon of highly developed religion. Individualistic in character, it is the outcome of a longing for intimate communion with the Divine. The mystery religions show a mystic tendency in their doctrine of union with the god through the sacramental meal. The same is perhaps true of Hindu Yoga which is a method of inducing religious ecstasy by concentration and absorption of mind. The Yogin became for others a kind of supernatural being. But mysticism proper is a conscious reaction against the externality of a merely intellectual knowledge of God: its goal is a perfect union with the Deity in which the element of difference implied in thinking is overcome. The Neoplatonic union of the

soul with the One is a purely mystical experience. The same spiritual movement appeared within Islam in Sufism, which no doubt was influenced by Neo-Platonism. The sufi sought to purge his mind of all that was not God, and the perfect man attained to absorption in God. The great mediaeval mystics sought the same consummation, an *unio mystica* achieved by transcending the form of thinking. Mysticism is loosely related to official and institutional religion. Possessing a "more excellent way," it can dispense with the recognized means of mediation. But if it invests religion with a new warmth and intimacy, it is deficient as a social power. And mysticism is always exposed to the danger of falling into pantheism. (See MYSTICISM.)

(3) *Monothelism.*

Monothelism is a late phenomenon of religion. The hypothesis of a primitive monothelism lacks foundation, and is intrinsically improbable. Beyond doubt the spirit and meaning of religion attain their fullest and best expression in some form of monotheistic faith. Polytheism disperses the religious interest: intimacy of worship and the confidence of trust are only possible when there is one, and only one, object of religious devotion. The trend towards monothelism was gradual, and it had preparatory stages. The first stage was what is called monarchianism. After the analogy of human society one deity is exalted above the rest, and becomes the king of the gods. A familiar example is the Homeric Zeus who stands supreme over all the gods and looks down on the conflicts of mortals among whom his will is accomplished. (*Διὸς δ' ἐρέελερο βουλή*.) The Babylonian Marduk and the Egyptian Ra are illustrations of the same phenomenon of one deity attaining a position of undisputed sovereignty. A rather more advanced stage is that of monolatry, where other gods are admitted to exist, but worship is reserved for one. This we find in Hebrew religion in the pre-prophetic period.

The earliest attempt—an abortive one—to introduce a pure monothelism, in this case a solar monothelism, is that of the Egyptian Amenhotep IV, in the XIVth century B.C. More impressive is the monothelism of Zoroastrianism, perhaps some eight hundred years before our era. This monothelism rests on a comprehensive view of the world. The physical and moral order derive from the one God, his will is right, and all the pure elements of life belong to his kingdom. The pronounced dualism of the later Avesta is absent from the prophet's teaching. With the eighth century prophets of Israel the earlier monolatry became a true monothelism. This monotheistic universalism finds its clearest utterance in the work of Deutero-Isaiah. From this heritage of Hebrew religion Christianity derived its pure monothelism, and the same influence is manifest in the monothelism of Islam.

Monothelism is the ripest expression of the religious consciousness. It rests on the conviction that the ethical and religious values must have a sufficient ground, and this is the one God on whom all existence and value depend.

VII. REVELATION AND THEOLOGY

Belief in the communication of truth to man from a divine source is common in religions. This kind of communication usually concerns the future, and may be subject to a process of interpretation. Hence the practices of divination, the reading of omens and auspices, and star-lore. But the communication may be in and to the individual, for instance through visions and dreams.

(1) *Revelation.*

More especially is revelation thought to come through inspiration or "possession" by a divine power. The words spoken by the individual thus "possessed" are identified with the utterances of the god. The Greek Apollo was the god of prophecy, and the words spoken by his inspired priestess at Delphi were deemed to be the authentic voice of the god himself. The religious value of revelation depends on the character of the deity who is believed to reveal; and it is the consciousness of ethical values leading to an ethical idea of deity which purifies the content of revelation. Revelation in the large and comprehensive sense is linked with monotheistic religion. So Zoroastrianism proclaimed the message communicated to him by Ahura Mazda, and Mohammed in his

visions had the truth revealed to him by Allan. The divine word came to the prophets of Israel, and the preface to their message was, "Thus saith the Lord." What they spoke Jahveh had caused them to know. At this level revelation centres in an experience or illumination within. But these inspired utterances were afterwards written down and collected: in the form of sacred books they came to be regarded as objective statements of divine truth. Hence the claims made for the Avesta, the Veda, the Koran, and the Old and New Testaments. Books which were accepted as statements of revealed truth naturally became authoritative, and as expressing authoritatively the content of a religion they furnished a basis for theology.

(2) *Theology.*

Theology grows out of the beliefs contained in an historic religion: it is an endeavour to state what is involved in a definite religious type of experience in general propositions or doctrines. The earliest anticipation of this is the myth framed to explain the meaning of something done in the cult. Theology is not detached like speculation, it is a natural and necessary outgrowth from the life of religion itself. It is the product of a mature religion, and commonly has its basis in the sacred books which record its religious experience. We find theological developments in Judaism and Buddhism, but in a more complete form in Islam and in Christianity. The Islamic and the Christian theologies claim to interpret the authoritative revelation contained in their sacred scriptures. In both instances the growth of theology was stimulated by the presence of beliefs judged to be heretical. The Mutazalite movement, with its doctrines of faith and free-will and its criticism of tradition, impelled the orthodox party in Islam to define the true doctrine of Allah and his attributes. In a like way the Gnostic heresies provoked the growth of a Christian theology which sought to expound the doctrines involved in Christian faith and practice. The Islamic conception of religion, however, is too much interwoven with what is external and political to furnish a favourable field for theological development. Christianity, on the other hand, has developed a body of religious experience of a wealth and amplitude capable of sustaining an impressive body of doctrine.

The function of theology is primarily to interpret. As contrasted with speculation it leans on authoritative revelation, and stands in organic relation to a specific historic religion. (See THEOLOGY.)

VIII. ETHICS AND ESCHATOLOGY

The ethical element is of fundamental importance in determining the quality of a religion: it is a powerful factor in elevating the object of worship, the religious relation, and the religious life. At the pre-deistic stage the sacred is interpenetrated with magical beliefs, and ethical principles have their lowly precursor in the sanctity of tribal custom. When through the growth of social culture the moral virtues are recognized as values, they are made to qualify the character of the gods.

(1) *Ethics.*

The process may not be easy when the deity has a pronounced natural basis, but still it does occur, as in the case of the Vedic Varuna and the Babylonian Shamash. On the other hand, the Persian Ahura Mazda became a definitely ethical god who demands pure living and right thinking. At a later date Mithra was revered as the god of truth and loyalty. The Greek Zeus acquired moral functions, and *Δίκη*, or Justice, was proclaimed to be his daughter. The feeling for the moral element in religion appears in the saying of Euripides: "If the gods do aught that is shameful, they are no gods." A profound appreciation of the moral values is seen in the Hebrew prophets who passionately declared that Jahveh is a righteous God who demands righteousness in his people. And when men cherish the conviction that the divine Power is righteous, the efficacy of sacrifice is made to depend on moral conditions.

Through the interpenetration of ethics with religion the sphere of the sacred is enlarged, and the moral life becomes an aspect of the religious vocation. Moral laws rank as divine commands, and ethical duty as a religious obligation. On the other hand, when the notion of divine personality is weak or lacking, ethics inevi-

tably assume a worldly or a negative character. Chinese religious ethics, for instance, founds on the idea of Tao or world-order, and man's duty is to reflect this order in his life. The ethical ideal is one of conformity, propriety and measure. A like utilitarianism is present in the Roman *pietas*, the knowledge of the *ius divinum* which enables a man to keep on profitable terms with the divine powers. The negative conception of ethics is strongly marked in Buddhism, which, in its original form, had no deity. The ideal of the Arabist is merely an ascetic discipline by which the dominion of desire and sense may be extinguished and Nirvana attained. In strong contrast is Christian ethics which rests on an ethical monotheism. Here the ideal is positive, the development of man's ethical life as a member of the Kingdom of God.

(2) Eschatology

The problem of eschatology is the ultimate destiny of man and the world. It is a problem which lies in the background of the religious consciousness, though eschatological motives may powerfully affect the working of religion. Thus eschatology looms large in the old Egyptian, the Christian and the Islamic religions, but it plays a feeble part in the Babylonian, the old Hebrew and the early Greek religions. There is no side of religion where the survival of old ideas is more apparent, or where the presence of inconsistent elements is more conspicuous. This is intelligible; for eschatological ideas do not lend themselves to verification in religious experience, and they offer an ample field for religious imagination.

Primitive eschatological ideas gather round the fate of the dead, and are unequally by ethical elements. Two factors promote the growth of eschatology in higher religions, a quickened moral consciousness and the sense of the value of the individual. If ethical ideas, however, be cast in a utilitarian mould, the eschatological interest may be slender; and even though they are of a higher order, as in Hebrew Prophetic religion, the merging of the individual in the people as the religious unit has the same result. Post-Exilic Judaism gained a new sense of the value of the individual, and felt the need of retribution, and this led to decided eschatological developments. In Buddhism, where ethics are negative and personality an obstruction rather than a value, eschatological doctrine is nebulous in the extreme.

Of the ethical ideas which promote eschatology the most prominent is that of justice, for it directly suggests the notion of future rewards and punishments. Justice, it is felt, is only imperfectly done on earth. The Osiris-Religion of Egypt figured the soul of the dead man ushered into the judgment-hall of Osiris, where his deeds were weighed in a balance. Those who pass the test go to serve Osiris in the fields of Earu. In the Avesta, Shraoshi, the guide of souls, is said to lead the just over the heavenly bridge to the gate of paradise. Orphism taught that the initiated were rewarded by a happy life in the Elysian Fields, while the wicked were cast into Tartarus. In the Persian, Christian, and Islamic religions, along with the judgment of the individual there is conjoined the idea of a world-judgment and the final separation of the good from the wicked.

The fuller development of eschatological doctrines belongs to the ethical and redemptive religions. But no religion has done this consistently, and eschatology remains the most backward aspect of religion. Here the material and the ethical, the sensuous and the spiritual, are often incongruously blended, and old beliefs survive in an alien environment. The Islamic eschatology, for instance, is on a lower level than that of a religion of salvation. And Christian eschatology, at least in its traditional form, is only imperfectly spiritualized. The problem of a consistent eschatology is a difficult one. (See *ESCHATOLOGY; IMMORTALITY*.)

IX. CLASSIFICATION OF RELIGIONS

Various attempts have been made to classify religions, but with only partial success, and there is no generally accepted scheme. Every religion is a complex of many elements, and there is no one specific feature which adequately characterizes it. One of the earlier classifications is that of Hegel into Nature-Religions, Religions of Spiritual Individuality, and Absolute Religion. But he arbitrarily groups together very disparate materials, and in

the light of modern knowledge the scheme is unworkable. Edward Caird's revision into Objective, Subjective, and Absolute or Universal Religion is less open to this objection, but it is too vague and too much dependent on a particular philosophic construction of religion. Tiele adopts a very broad classification into Nature-Religions and Ethical Religions, while Siebeck groups religions into Primitive Religions, Morality-Religions, and Redemptive Religions. The latter scheme is certainly suggestive, though the distinction between ethical religions and redemptive religions can hardly be carried out consistently. Even the broad distinction between natural and ethical religion would have to be applied rather arbitrarily.

In the classification of religions into Tribal, National, and Universal, the line of demarcation is much more distinct and can be more easily used. But it may be objected to this classification that it is based on a principle which gives no clue to the character and content of the religions. Moreover it may be said that no religion is *de facto* universal. And from an evolutionary standpoint it is a defect in a classification that it ignores the principle of valuation.

The complexity and variety of the materials render a complete and consistent classification impracticable. But it is always possible to apply different criteria in surveying the religious field. Religions may be grouped according to their conception of the Divine, according to the types of piety they foster, or according to the ideal after which they strive. But such classifications will be merely provisional: though suitable for the purpose on hand, they cannot claim to be comprehensive and final.

BIBLIOGRAPHY.—Monographs dealing with particular religions will be found under the respective headings. The literature on religion is vast, and only a few of the works likely to be useful are noted here.

(a) *Histories of Religion.*

The most compact and complete history, embodying the results of recent research, is the *Lehrbuch der Religionsgeschichte*, edited by Bertholet and Lehmann, 2 vols. 1925. G. F. Moore, *History of Religions*, 2 vols., 1914, 1920. A. Moniez, *History of Religion* (1st ed., 1895, and later editions). Toy, *Introduction to the History of Religions* (1913). The *Religionsgeschichtliche Lexikon* (1908), ed. by Bertholet, gives a translation of extracts from the chief religious classics. A new edition is appearing. There is also the *Textbuch zur Religionsgeschichte* (1912), by E. Lehmann.

(b) *The General Development of Religion.*

E. Caird, *The Evolution of Religion* (1894). Tiele, *Elements of the Science of Religion* (2 vols., 1897 & 1898). Bousset, *Das Wesen der Religion* (1904); Galloway, *Principles of Religious Development* (1909). King, *The Development of Religion* (1920). Karmel, *Greece and Babylon* (1911), and *Attributes of God* (1925). Wundt, *Mythos und Religion* (1909). G. F. Moore, *The Birth and Growth of Religion* (1923). Some works of more restricted scope are valuable for the light they cast on religious development, e.g. W. R. Smith's *Religion of the Semites* (3rd ed. 1927), Nilsson's *History of Greek Religion* (1925), and Warde Fowler's *Religious Experience of the Roman People* (1911).

(c) *Psychology and Philosophy of Religion.*

For the Psychology of Religion James's *Varieties of Religious Experience* (1902), Stratton's *Psychology of the Religious Life* (1911), Pratt's *The Religious Consciousness* (1923), will be found useful, and other work equally deserving mention.

Hegel's *Philosophie der Religion* (1840) is historically important. Among other works on the subject are those of J. Caird, Rauwenhoff, Höfding, Siebeck, Pfleiderer, Galloway and Ladd. (G. Ga.)

RELIGION, WARS OF (1562-1609). The so-called Wars of Religion opened with the massacre of sixty Huguenots at Vassy in 1562, and ended with the declaration of the twelve years' truce between Spain and Prince Maurice of the Netherlands in 1609. They included eight civil wars in France, the revolt of the Netherlands, and a number of less important rebellions. Though outwardly religious in character, inwardly they were influenced by economic and financial causes, constituting as they did a revolt against the fiscal policy of the mediæval papacy.

Causes and Personalities.—During the Crusades the Church became an all-controlling power, establishing its own law courts, its own tax collectors and its own prisons in nearly every European country. As long as the various kings were occupied in mastering their feudal nobility the papacy remained all-powerful, but once control over them was established the next conflict was between the more progressive of the kings and the pope. This

quarrel centred round the questions of appointments, taxation, "benefit of clergy" and the interference of the pope in national government. In 1296, Edward I. of England demanded one-fifth of the personal property of the clergy, and four years later Philip the Fair of France openly quarrelled with Boniface VIII. over taxation. A religious-economic conflict then began which lasted until the peace of Westphalia in 1648.

In England, John Wycliffe began to preach reform about 1366. Eleven years later the papacy moved back from Avignon to Rome, and the whole question of papal control was thrown into the melting pot. Then arose the question of whether a general council of Christendom was not superior to the papacy. This question gave rise to the Council of Constance in 1414, which, in 1415, condemned Hus, a Bohemian reformer influenced by Wycliffe, to be burnt. This in turn brought about the Hussite wars (1419-1436)—the forerunner of the wars of religion.

By the opening of the 16th century discontent against the Church was general, especially so in Germany, and all that was wanting were leaders. These, as is always the case during revolutionary periods, soon came to the fore. The most prominent were Erasmus, a Dutchman (1469-1536); Luther, a German (1483-1546); Zwingli, a Swiss (1484-1531), and Calvin, a Frenchman (1509-1564). Erasmus was an evolutionary, he believed in a slow and steady change; Luther was the reverse, he wanted immediate change, and his doctrine of "justification by faith" sent a thrill of horror through the Catholic Church. He was a democrat and an economist as well as a religious reformer. He attacked "indulgences," and said: "Since the pope is rich as Croesus, why does he not build St. Peter's with his own money, instead of taking that of the poor man?" In 1520 he was excommunicated, and this same year at Wittenberg he threw the Papal bull into the flames. He was of opinion that the power of the papacy rested on money, and if money was withheld in two years the papacy would vanish.

Turmoil.—The results of his teachings led to a peasants' war in Germany in 1525. In Switzerland, Zwingli (the originator of the name Protestant) attacked the Church, and the first conflict between Protestants and Catholics took place at Kappel, in 1531. In France Calvin's doctrines, based on the infallibility of the Bible in place of that of the Church and pope, gave rise to the Huguenot and Presbyterian movements. Meanwhile, in England, out of Henry VIII.'s first divorce arose a quarrel with Rome which ended in 1534 in the revolt of the English Church from the pope and in the closing of the monasteries, whereby Henry enriched himself.

The greatest part of Europe was now thrown into a spiritual and economic turmoil. On one side stood religious freedom confronted by papal infallibility, on the other fiscal control faced by papal anathema. Nations, cities, villages and families were divided. A general Council of the Church was held at Trent in 1545, but the Protestants refused to attend. The "Society of Jesus," founded by Loyola in 1538, gained strength, its scientific system of propaganda rousing the fury of the Reformed Church.

Hostilities in France.—The first dash came in France which had been stirred by the preaching of Lefevre (1450-1537). Henry II. (1547-1559) swore to extirpate the Protestants, and burnt them in hundreds. He was succeeded by his son Francis II., a boy of sixteen married to Mary Queen of Scots. As Francis was too young to rule, the duke of Guise put himself at the head of the army, and when Francis died, in 1560, the duke was reluctant to surrender his power so that a conflict soon arose between him and the Huguenots under Coligny, merging, in 1562, into the First Civil War. An indecisive battle was fought at Dreux; then two other civil wars followed, in which battles were fought at St. Denis in 1567, and Jarnac and Montcontour in 1569. These were concluded by the peace of St. Germain, according to which the Huguenots were to be tolerated, Coligny being received on friendly terms by Charles IX. of France and his mother, Catherine de' Medici.

The Catholic party of the Guises, determining to put an end to this friendship, plotted and carried out the massacre of St. Bartholomew on August 23, 1572. The result was the Fourth Civil

War which was followed by the fifth, sixth, seventh and eighth. The last of these known as the war of the three Henries—Henry III., Henry of Navarre and Henry of Guise—ended with the assassination of the first and third, leaving Henry of Navarre, now Henry IV., the national hero. In 1590, he won the battles of Arques and Ivry, and to put an end to the war, in 1593, re-entered the Catholic Church. In 1598, he issued the Edict of Nantes by which the Calvinists were permitted to worship as they chose, and to be eligible to hold government appointments. Meanwhile an even more terrible war was being waged in the Netherlands.

Spain and the Netherlands.—In the second half of the 16th century, the chief ally of the pope was Philip II., son of the emperor Charles V. Charles though a firm Catholic was not a fanatic; Philip's attitude was very different, for he was willing to sacrifice everything so long as the Protestants were exterminated. In 1555 Charles abdicated, handing over his Habsburg possessions to his brother Ferdinand, and Spain, the American Colonies, the Two Sicilies and the Netherlands to his son Philip. For ten years the Dutch suffered Philip's rule. Then in 1566, five hundred of the nobles protested against his policy. Thereupon Philip sent the duke of Alva to the Low Countries. William of Orange fled to Germany and thousands of Flemish weavers sought refuge in England. Alva's administration was a veritable reign of terror. Though not unaccustomed to persecution, for Charles V. had burnt many of them, the people revolted and found their leader in William, Prince of Orange and Count of Nassau (1533-1584), who in 1568 collected together a small army and opened the wars of religion with Spain. Defeated again and again he was never conquered, and in 1572 the northern provinces of Holland chose William as their governor.

After six years of tyranny Alva was recalled, but this did not improve things as his leaderless soldiers committed every possible atrocity. The north, guided by William, now refused to recognise Philip as their king, and the Union of Utrecht followed in 1579, by which the United Provinces were constituted. Two years later these provinces declared themselves independent of Spain. Philip realising that William was the heart and soul of the revolt offered a patent of nobility and a large sum of money to anyone who would assassinate him, with the result that the great patriot was shot at Delft in 1584.

His son, Maurice of Nassau (1567-1625) succeeded him, and was made stadtholder. When Queen Elizabeth of England decided to send troops to his assistance, Philip was so enraged that he determined on the conquest of England, and, in 1588, equipped and despatched the "Armada." Its defeat and destruction as well as the falling resources of Spain were of the greatest assistance to Maurice, who soon showed himself to be a general far in advance of any of his contemporaries. A great campaign was fought in 1597. From then onwards to 1609 battles were waged and sieges undertaken, and though Maurice was by no means always successful, as was notably the case in 1605, the power of Spain was definitely on the decline, and in 1609 a twelve years' truce was concluded and the United Provinces took their place in the European system "as a free and independent State."

This truce was but an interlude in the struggle for freedom, for in 1618 the Thirty Years' War (*q.v.*) broke out, and it was not until it ended with the Treaty of Westphalia in 1648, that once and for all the semi-religious conflict of nearly 100 years was brought to an end, Europe emerging out of the night into the daylight of modern history.

Bibliography.—The bibliography of this period is extensive, and the reader is referred to *The Cambridge Modern History*, vol. iii, 1504, and especially to the full list of books at the end of the volume. (J. F. C. F.)

RELIGIOUS AND MEMORIAL ARCHITECTURE.

The earliest religious buildings were not so much congregational as shelters for the mysteries or provisions for the rite, sometimes consisting merely of an altar; and the earliest memorials were a stone or a mound. Even the Egyptian temple, with its court guarded by pylons or towers and approaching avenue of sphinxes or colossal human figures, was a sanctuary for kings and priests

rather than a place of worship for the people; and the pyramids were the tombs of kings, furnished with the necessities of the future life (see EGYPTIAN ARCHITECTURE). The Greek temple, with its central shrine for a statue of the god or goddess, porticoes to front and rear, and flanking colonnades, was more like a place of worship as we understand it to-day. It was at least a public building. Greek memorials were generally tombs (see GREEK ARCHITECTURE). The Roman temple, of which the construction was determined by the blending of the Greek columnar system with the Etruscan arch, came nearer than the Greek to the Christian church in plan; the *cella*—used as a treasury or as a museum of sculpture and frequently occupying the whole width of the building—corresponding to the chancel or sanctuary, and the deep portico and steps of the entrance anticipating the west front. A favourite form of Roman memorial, reflecting a proud spirit, was the triumphal arch (see ROMAN ARCHITECTURE).

Early Christian and Mediaeval.—It is probable that the earliest Christian churches, in countries under Persian rule, were humble structures of wood, clay, or at the most brick concrete, in the form of a shrine for an altar where two or three might be gathered together. Such churches, of which remains have been found in Syria, Palestine, Armenia and north Africa, were concentric in plan—that is to say, square, circular, octagonal or cruciform—and roofed with a dome. With the conversion of Rome to Christianity in the 4th century, and the establishment of Constantine's new capital at Byzantium, a more congregational form of church was evolved by adjustments between the domed, concentric shrine and the plan derived from the Roman basilica, or hall of justice. In the Eastern empire the interactions between East and West were extremely complicated, and authorities still differ about the respective shares of Greek, oriental and Roman influence in forming the religious architecture that we call Byzantine. The result, however, was a square, circular, octagonal or cruciform church of brick and concrete, with a central space covered by the principal dome, and arms or extensions covered by subsidiary domes. One arm was provided with an apse for the altar—now removed from the centre of the building—and another with a narthex, or porch. Decoration took the form of a continuous sheathing or "skin" of marble and mosaic. St. Sophia, Constantinople, and St. Mark's, Venice, are famous surviving examples.

In the Western empire development was simpler, and the earliest Christian churches in Rome itself were copies or even adaptations of Roman buildings, frequently embodying fragments of pagan temples in their construction, following, with internal modifications, the plan of the basilica. The usual arrangement of basilican churches was that of nave and aisles, divided by arcades, with a semi-circular apse for the altar and a choir enclosed by low screen walls at one end, and a covered narthex, or porch, preceded by an open court, or atrium, at the other. From the basilica, with some refection from the East, was evolved the form known as Romanesque. The addition of transepts and the prolongation of the sanctuary resulted in a cruciform plan, and the flat wooden roof of the basilica was gradually exchanged for vaulting in stone. In northern Italy conditions favoured a mixed style, so that it is sometimes difficult to say whether a particular building should be described as Byzantine or Romanesque, but in passing down the Rhine and extending into France and Germany Romanesque became more clearly defined, reaching England finally in the form we know as Norman. (See BYZANTINE AND ROMANESQUE ARCHITECTURE.)

Gothic, which may be dated from the 12th century, proceeded logically from Romanesque by the substitution of the pointed for the round arch and the development of rib vaulting—changes which enabled unequal spans to be vaulted to the same height and smaller units of inferior materials to be used for filling the spaces between the ribs. With the progress of Gothic the onus of stability tended to be put more and more upon the stone skeleton, with its elaborate system of thrust and counterthrust, the downward pressure of the nave vaulting being met externally by buttresses and flying buttresses, while the inactive wall-spaces were pierced by larger and larger traceried window openings filled

with stained glass. Architecturally the Gothic church was a collaboration of many kinds of craftsmen—masons, carvers, painters and glaziers—organized into guilds and working more or less "freelance" under a master mason, and ecclesiastically it was adapted to the requirements of a powerful priesthood. Its characters can be studied to advantage in Chartres and Reims cathedrals in France, and Westminster Abbey and Canterbury and Wells cathedrals in England.

FROM RADNOTY AND PEREVALT, "CATHÉDRALES DE FRANCE" (LAURENS).
FIG. 1.—PLAN OF CHARTRES CATHEDRAL.

Europe, at any rate, the Renaissance and the Reformation went hand in hand in deciding the form and character of churches. As was natural, the revival of Roman architecture began in Italy, where the tradition survived, and it gradually spread to the rest of Europe with local modifications due to the resistance of native styles. For our purposes the critical example is St. Paul's cathedral, designed by Sir Christopher Wren and built between 1675 and 1710. Disliking Gothic, which he called "barbarous," Wren observed that the chief requirement of the Reformed religion was a preaching space or auditorium. His first design for St. Paul's was a Greek cross in plan, and though clerical opposition compelled the adoption of a Latin cross he carried out his ideas to some extent in the great space under the dome at the crossing of the transepts. His other city churches, of which St. Stephen, Walbrook, and St. Mary-le-Bow are examples, were frankly rectangular sermon halls with at most a shallow recess for the communion table. The plan of church introduced by Wren persisted through the 18th century, as may be seen in St. Mary, Woolnoth, by Wren's pupil Hawksmoor, and St. Martin-in-the-Fields and St. Mary-le-Strand, by James Gibbs.

Even on the Continent, in countries untouched by the Reformation, the revival of Roman architecture restored a similar plan, as we see in the Pantheon and the churches of St. Sulpice and the Madeleine, Paris. In Italy and Spain the Renaissance passed into Baroque, with its free handling of form without reference to construction, and florid ornament, characters which have been associated with the religious movement known as the Counter-Reformation (see BAROQUE ARCHITECTURE). The memorials of the Renaissance period are chiefly sculptured tombs, in which Christian and classical sentiment are blended (see RENAISSANCE ARCHITECTURE).

In England the general tendency of the Renaissance in church designing was interrupted by the Gothic revival. Its earliest phase, like that of the Renaissance itself, appears to have been purely literary and romantic, but as time went on it became associated with the definitely religious Oxford Movement of High Anglicanism. Contributing causes were undoubtedly the scientific materialism of the 19th century, which sharpened and stiffened the religious attitude in opposition, and the observed effects of the industrial revolution, which made men like Ruskin look for a remedy in the revival of handicrafts (see MODERN ARCHITECTURE: 18th and 19th Centuries).

The Orient.—The many examples of religious and memorial architecture in the countries of Asia are treated in the articles CHINESE ARCHITECTURE; INDIAN ARCHITECTURE; JAPANESE ARCHITECTURE; MOHAMMEDAN ARCHITECTURE. It is interesting to note here that the aspiring quality of the Gothic is also expressed in religious architecture in the Orient.

FROM BIRCH, "LONDON CHURCHES OF THE 17TH AND 18TH CENTURIES" (INTROD).
FIG. 2.—PLAN OF ST. MARY-LE-BOW.

THE MODERN PERIOD

For present purposes the modern period may be regarded as the last 60 years, with special emphasis upon the first half of the 20th century. When considering the causes which led to the more practical designing of churches after the Gothic revival we are inclined to give first place to the decline of materialism as a respectable philosophy and the consequent easing of the conflict between science and religion. Pressure removed, there was not the same need for the church to insist upon the outward forms of its past. At the same time there was a change in the spirit of industry. It began to be recognized that though craftsmanship—in the mediaeval sense—could not be revived, self-interest required that mechanical skill should be given its best opportunity. The result, in religious architecture, was a broader system of planning, to the actual requirements of the religion of the day rather than to advertise its historical claims, and a more intelligent use of the mechanical skill that survived, instead of a hankering after a craftsmanship impossible to restore.

Great Britain.—The first important result of the new spirit in religious architecture in Great Britain was the Roman Catholic cathedral of Westminster, designed by John Francis Bentley (1839-1902) and begun in 1894. Bentley himself would have preferred a Gothic design, but several good reasons were given for the Byzantine building decided upon: a wide nave and a view of the sanctuary best adapted to the congregational needs of a metropolitan cathedral; economy—since the whole space could be covered and the whole building erected, apart from decoration and ornament, which in other styles would form a substantial and costly part of the structure itself; avoidance of hopeless competition with Westminster Abbey; an opportunity to suggest an international character by the use of a style associated with inclusive primitive Christianity up to the 9th century. Externally Westminster cathedral is remarkable for its tall campanile, and for the bold use of brick and stone in alternating bands. The interior consists of a vast nave of three bays, 60 ft. square, each surmounted by a saucer-shaped concrete dome. A fourth bay, with a more elaborate dome, 52 ft. in diameter and pierced for the admission of light, forms the sanctuary, and behind it is the apse, with a raised retro-choir visible from the whole of the nave. Each bay of the nave is divided by lesser piers and again by monolith columns, forming an arcaded aisle.

With Liverpool cathedral, designed by Sir Giles Gilbert Scott, R.A. (b. 1880) at the age of 22, and begun in 1904, there was a return to Gothic, but Gothic with a difference. Liverpool cathedral is an example of designing in mass instead of in line, the style being a free interpretation of Decorated or 14th century Gothic (see DECORATED PERIOD) and the material a warm red

BY COURTESY OF THE LIVERPOOL CATHEDRAL COMMITTEE

FIG. 3.—PLAN OF LIVERPOOL CATHEDRAL

sandstone, with dressings of lighter stone. Standing on the summit of a rocky mass, St. James's Mount, in the heart of the city, the building when completed will consist of a central square space rising into a great tower crowned with an octagonal lantern, with eastern and western transepts and two oblong extensions, nearly equal in length, forming the nave and choir. In a side view the central mass formed by the tower and transepts will be absolutely, and the whole building nearly, symmetrical, the choir having a different termination to that of the nave. A striking feature of Liverpool cathedral is the great size of the bays which make up

the nave and choir—three only occupying the space which in older buildings would be divided into something nearer ten. Each bay is lighted by a single two-light window, and the aisles are reduced to passage-ways through the return walls, continuous with the buttresses outside, which divide the bays.

In the space of a short article dealing with the modern religious and memorial architecture of the world it is not possible to select more than a few significant examples, preferably those with the most modern characteristics. From this point of view there is a special interest in churches associated with town-planning schemes (see TOWN AND CITY PLANNING). Earliest in order of date are the church of St. Jude's-on-the-Hill and the free church in the Hampstead garden suburb, designed by Sir Edwin Lutyens R.A. The strongly domestic flavour of these, with their deep tiled roofs and cornices at the level of those of the surrounding houses, is in keeping with the communal ideals of a garden suburb. Naturally it is in the neighbourhood of London, with its rapid growth of population, that some of the most characteristically modern churches are to be found. St. Catherine Coleman, Hammersmith, designed by Robert Atkinson F.R.I.B.A., is essentially a rectangular auditorium with short chancel, both barrel vaulted by means of steel arches embedded in concrete, faced externally with London "stock" bricks and roofed with pantiles, and finished off internally with a surface of rough plaster. The stylish allusion is Byzantine, which appears to be the natural consequence of brick and concrete building for congregational needs. Within a few hundred yards of St. Catherine Coleman there is an exceptionally beautiful church, St. Saviour's, designed by Edward Maufe F.R.I.B.A. for the Royal Association in Aid of the Deaf and Dumb. In this church, which is of brick in a free interpretation of Decorated or 14th century Gothic, everything is adapted to sight to the exclusion of hearing. There is no organ and no provision for a choir, the clergy seats being in two "ambos" set at an angle to keep the occupants in full view, the nave walls play in to the chancel, the floor rakes as in a theatre, and there is a western gallery. A feature of the interior is restful colour decoration.

St. Barnabas mission church, Dalston, designed by Prof. C. H. Reilly F.R.I.B.A. and built about 1910, is an example of an urban building so closely surrounded that it can be seen only as an interior. This, of London "stock" bricks, is of almost startling grandeur; the brick being used, not as by Bentley at Westminster as a support for marble sheathing, but for its own decorative effect; the full colour value being brought out by the use of white metal instead of brass for candlesticks, chancel gates and other fittings. Unlike most modern churches below cathedral rank, St. Barnabas has what amounts to a choir, formed by the crossing of the shallow transepts, saucer-domed in concrete above and separated from the barrel-vaulted nave of three bays by a wooden screen of four columns supporting the roof beam. The special point about St. Andrew's, Ilford, designed by Sir Herbert Baker, R.A., is that it is an exercise in brick and timber construction, giving full opportunity to the native craftsmanship in these materials, the only stone employed being in the chancel flooring, the corbels supporting the roof timbers and the font. Characteristically modern is the addition of decorative details by prominent artists and craftsmen; an altar and reredos carved by Lawrence Turner, a triptych painted by Colin Gill, a lunette of glazed pottery—in the baptistry—by the Poole Potteries, and, externally, a bronze figure of the angel of peace by Charles Wheeler.

Mention must be made of a few other recent churches in England of special architectural interest. In the neighbourhood of Liverpool and elsewhere Sir Giles Gilbert Scott has designed several churches in his characteristic manner of moulded Gothic—as it might be called in distinction from the stone skeleton construction of the middle ages—St. Paul's, Derby lane, Liverpool, being a good example.

As an instance of planning to requirements, combining the maximum of space and unimpeded movement, sight and hearing with a dignified architectural effect, special mention must be made of the new church at Hindley, Lancashire, designed by Robert Atkinson F.R.I.B.A.

CHURCHES AND MEMORIALS

1. First Plymouth Congregational Church, Lincoln, Nebraska. H. Van Buren Morgan, Robert W. McLaughlin, Jr., Architects Associated.
2. Memorial Terrace entrance to Forest Lawn Mausoleum, Glendale, Calif. Forest Lawn architectural department, architects.
3. West face of American war memorial near Chateau-Thierry, France. Dr. Paul P. Cret, architect.
4. Washington Cathedral, Washington, D.C., as it will appear when completed. Frohman, Robb and Little, architects.
5. The proposed Broadway Temple in New York city, designed originally by Donn Barber (1871-1925).

With the exception of Westminster cathedral which has already been described all the buildings we have been discussing belong to the Established Church of England. To a certain extent the characters described—congregational plan, and construction in terms of contemporary labour and most readily available materials—are common to the modern churches of all creeds and sects, but every creed has its particular requirements. Naturally the Roman Catholic Church puts the emphasis upon its Roman tradition, with a preference for the basilica form, and the somewhat exuberant Baroque of the Brompton oratory, by Herbert A. K. Gribble, finds more sober echoes elsewhere. Beyond dispensing with the chance the Protestant Free Churches of England do not follow the lead, peculiarly suitable to their requirements, given to them by Wren, but rather surprisingly cling to Gothic, though here and there, as in the Broadway Congregational church, Hammersmith, by Cecil M. Quilter, the plan of the sermon hall is frankly adopted.

Christian Science, however, has followed a bolder policy, and all its churches in England are designed as auditoriums, with a platform for the "readers" and a screened organ chamber in place of a chancel, and generally a raking floor, as in a theatre. One of the most recent examples, the Eleventh Church of Christ, Nutford place, Brynston square, by Oswald P. Milne F.R.I.B.A., seems to have arrived at a perfect adjustment between form and requirement, and is in every respect an admirable building, proclaiming at a glance its purpose and construction as an auditorium with a very wide span of roof, buttressed at each corner by a tower-like bastion or pavilion containing a staircase. The interior, which will seat 600, is designed to allow complete circulation of the building without disturbing the congregation.

In memorial architecture the most extensive work in England during the period under review is the memorial to Queen Victoria, in front of Buckingham palace, designed by Sir Aston Webb R.A. Otherwise the memorial architecture of the period resolves itself inevitably into war memorials. Of these by far the most important, by reason of its wide appeal, is the cenotaph in Whitehall, designed by Sir Edwin Lutyens R.A., the stone of remembrance by the same architect, and the memorial cross by Sir Reginald Blomfield R.A. Modifications and combinations of these three architectural forms have been used as war memorials in several provincial centres.

Many war memorials, however, have taken the form of halls and chapels, either as new structures or as additions to existing buildings. The Scottish national war memorial is a reconstruction of part of Edinburgh castle, designed by Sir Robert Lorimer, A.R.A. On the site of an old barrack, and improving the general outline of the castle from a distance, the memorial is in the form of the letter E, with a heptagonal shrine, containing the memorial casket supported by a marble table, projecting at the back in line with the middle limb, which thus forms a porch allowing a vista into the shrine. The stem of the E forms a gallery of honour, with a bay for each of the 12 Scottish regiments; and, by means of stained glass, moulded bronze, carved stone and wood, metalwork and painting, the place is made a museum of illustrative symbolism—not only every type of soldier and the women's services, but even animals and carrier pigeons and the actual arms and materials used in the War being recorded.

Though not on English soil, reference must be made to the several important memorials designed by English architects for war areas in France and Belgium. Three in particular claim attention: the memorial to the missing at St. Quentin, by Sir Edwin Lutyens R.A.; the Menin gate memorial to the missing, Ypres, by Sir Reginald Blomfield R.A.; and the memorial to the missing, Ploegsteert wood, by H. Chalton Bradshaw, A.R.I.B.A. The last is a circular pavilion, the others taking the form of the triumphal arch with the provision of extensive surfaces for the inscription of names by means of vaulted passages.

The British Dominions.—With one exception religious architecture in the overseas dominions of the British empire cannot be said to show any very interesting modern developments. The noteworthy exception is Africa, chiefly through the initiative of Sir Herbert Baker A.R.A., whose cathedrals of Cape Town, Pretoria and Salisbury, Rhodesia, and other churches, show a most

interesting adaptation to local materials and conditions, working out, at Pretoria and Salisbury, as a spacious Romanesque-Byzantine type of building, with the exclusion of light except that from comparatively small clerestory windows. Among works in memorial architecture produced by or for the dominions must be named the "All India" war memorial, Delhi, in the form of a triumphal arch, by Sir Edwin Lutyens R.A.; the South African war memorial, Delville wood, France, by Sir Herbert Baker A.R.A.; and the Australian war memorial, Villers-Bretonneux, France, by William Lucas. The national war memorial for New Zealand is to take the form of an art gallery and museum, with a campanile and a hall of memories. In the mandatory country of Palestine there is the Jerusalem war cemetery, by Sir John Burnet R.A.

The Continent of Europe.—During the last 50 years, religious and memorial architecture all over the world has been moulded by the same influences: a less dogmatic attitude in religion and science alike, a decline in the social authority of the churches, a growth of the democratic spirit, and a progressive mechanization of labour accompanied by the discovery of new materials and methods of construction.

In France the modern period may be said to open with the basilica of the Sacré Coeur, Paris, designed by Abadie and begun in 1875. Standing on the summit of the Butte Montmartre, it forms a conspicuous object in the northern approach to Paris, and closes impressively the vistas of streets ascending from the main boulevards. Romanesque-Byzantine in style, the Sacré Coeur represents the first important break with the Renaissance tradition in France. Otherwise recent religious architecture in France is remarkable chiefly for daring experiments in reinforced concrete. The best known examples are the churches of St. Denis, Paris, Notre Dame, Raincy, and St. Thérèse, Montigny, by the brothers Auguste and Gustave Perret, in which an attempt has been made to work out forms proceeding logically from the material itself, used constructively, with very slender internal supports, and an elaborate tracery—or rather trellis—of concrete at the windows. In the Byzantine church at Vincennes, by J. Marast, which is faced externally with brick, the vaulting is carried out with deep concrete ribs, dividing the roof into panels, and dispensing with intermediate supports. Other interesting examples of religious architecture in France are the church of St. François, St. Etienne, entirely of reinforced concrete, the columns being supported by screw-jacks to allow compensation for movements caused by mining operations below, and the tower of St. Louis, Villenoble, by Paul Tournon, with sculptured decoration in concrete.

In Germany also, the chief interest is in the use of concrete, as in the churches by Prof. Dominikus Böhm at Neu-Ulm and Bischofsheim, near Mainz. In them concrete has been employed more solidly than in the French examples, with more emphasis upon the plastic mass of concrete than upon the steel supports, in a system of parabolic vaulting which, with its projecting ribs, intersecting to form complicated patterns in the roof, suggests a true translation of Gothic principles into the new material. Other recent German churches to be noted are St. Gabriel's, Munich, by O. Kurz and E. Herbert, in Byzantine-Romanesque, and the Protestant church at Ellingen, by Bestelmeyer, which is octagonal in plan, with circular galleries, and has a bulb-domed minaret or campanile.

Common to all the countries of Europe is an attempt to recover a national style from the Gothic and Classic revivals, which all have experienced in some degree, embodying the principles of both without their stylistic accidents; the energy of Gothic and the order and proportion of Classic. In Holland this takes the form of a development of the native brick construction, an excellent example being the church at Bussum, by Cuypers, a domed structure with round arches and vaulting ribs in brick. Other modern churches in Holland which call for mention as formal essays in brick construction are those at The Hague, by Kropholler, Bussum, by Rueter, and Utrecht, by Sluiter.

In Scandinavia the modern impulse appears to have originated in Denmark, where there are several interesting new churches, a

stepped gable, on both tower and transepts, being a characteristic feature. The church of St. Hans Tveje, Odensee, and Grundtvig's church—associated with a housing scheme—Copenhagen, by P. V. J. Klint, are striking examples. With their tall fluted towers, ending in stepped gables, they have a curiously organ-like effect. Among smaller and simpler buildings may be named Gurre church, by Carl Brunner, the church at Aarhus, by K. Gottlieb and A. Frederiksen, and the church at Frederiksberg, by Hanning and Frederiksen.

In Sweden the national style that is emerging from the various "revivals" in response to the modern spirit appears to be—paradoxical as it may sound—a fusion of the Byzantine and the Baroque, at any rate in religious architecture, with a substitution of lean and angular forms for the full curves we associate with Baroque in the South. Two famous examples are the Saltsjöbaden church, by Ferdinand Boberg, and Högalid church, Stockholm, by Ivar Justus Tengbom. Both churches are without aisles, the Saltsjöbaden church, which contains interesting sculpture in bronze and alabaster by Carl Milles, having a polygonal apse and a single tower; while the other, which is vaulted internally, the ribs being rectangular in section, has twin towers, rather oriental in character, with bulbous domes. Masthuggs church, Gothenburg, by Sigfrid Ericson, with its massive tower and open timbered roof; Engelbrecht church, Stockholm, by L. T. Wahlman, a high-shouldered, cruciform edifice, vaulted in parabolic curves; and the small chapels by Gunnar E. Asplund and Sigurd Lervrentz, the one circular and the other like a little Corinthian temple, in the cemetery at Enskede, are other interesting buildings.

In Czechoslovakia there is a vigorous architectural revival, with such results as the Palladian basilica of St. Venceslaus, Smichov, by V. Barvitijs, and the Romanesque church of Stechovice, by Kamil Hilbert.

Italy and Spain, being Catholic countries, have kept more or less on traditional lines in their religious architecture. In Italy a revival of Byzantine-Romanesque was followed by a return to Roman, of a simple and massive character, and under the present régime the Roman tradition is likely to be emphasized. Spain's most striking contribution to the modern period is the fantastic church of the Sagrada Família, Barcelona.

As regards memorial architecture Italy provides the most important example in Europe in the memorial to Victor Emmanuel II, Rome. Designed by Count G. Sacconi and begun in 1885, it takes the form of a great loggia, with columns 48 ft. high and end pavilions, with pediments, supporting sculptured groups. In front steps ascend to a platform bearing an equestrian statue of the king. Closing a vista at the end of the Corso Umberto, it is one of the most impressive monuments ever erected to one man. All the combatant countries of Europe have their share of war memorials, taking the forms already described and generally associated with sculpture. In Sweden note must be taken of the several recent memorials, mostly in the form of fountains, by Carl Milles. Though they are the work of a sculptor they are essentially architectural in general design.

The United States.—To an extent which does not prevail in any other country religious architecture in the United States of America is affected by two conditions: the upward growth of cities, and the shading off of religious beliefs into ethical systems. The first is leading inevitably to the incorporation of places of worship in business districts or in office buildings. Projects for churches in skyscrapers like the Broadway Temple, New York, begun by the late Donn Barber have been much publicized and in some cases even built in some of the principal cities; the second creates an intermediate type of building, something between the church and the lecture or concert hall, of which the Christian Science Church may be quoted as an example. Allowing for these special conditions religious architecture in America during the last 50 years has developed on very much the same lines as in England. The "colonial" version of the type of church instituted by Wren has persisted in the Congregational and Unitarian communities, Roman Catholic churches incline to the Lombard, or Romanesque-Byzantine form, and Christian Science prefers Classic; but Episcopalians and Presbyterians generally prefer

Gothic. To a certain extent, the broadening and simplification of Gothic associated in England with the names of Bodley, Temple Moore and Sir Giles Gilbert Scott, have been repeated in America, particularly by the late Bertram G. Goodhue and his associates Cram and Ferguson. Churches which may be named in this connection are St. Thomas', New York City; the chapel of the U.S. Military Academy, West Point; Emmanuel church, Cleveland, O.; and the First Baptist church, Pittsburgh, all by Cram, Goodhue and Ferguson; All Saints, Peterboro, N.H., by Cram and Ferguson; church of the Holy Innocents, Brooklyn, by Helmie and Corbett; and Washington Episcopal church, originally designed by Vaughan and Bodley and carried on by Frohman, Robb and Little.

The cathedral is a comparatively recent institution in the United States, and two important examples are now in course of construction.

In 1893 Congress granted a charter for the establishment and maintenance of a cathedral and institutions of learning within the District of Columbia for the promotion of religion, education and charity. Mt. Saint Alban, 400 ft. above the Potomac river, was chosen as the site for Washington cathedral; to-day the cathedral close occupies 67½ acres. Dr. George F. Bodley, of London, and Henry Vaughan, of Boston, his pupil, both of whom have since died, were the original architects chosen and their plan was accepted in 1907; the present architects are Frohman, Robb and Little, of Boston, with Cram and Ferguson, also of Boston, as consulting architects. The cathedral will be cruciform in shape with two impressive transepts, forming the arms of the cross. The total length will be 534 ft., the width at the transepts 215 ft., the area 71,000 square feet. The central tower will be 262 ft. and the western towers 195 ft. high. The entire foundation is now structurally complete. Three chapels in the crypt, together with the vaulted connecting passages, are now open. On the main floor the apse has risen, and the choir and crossing, including the great piers to support the central tower, are approaching completion. Through the western portal, the effect promises to be a vaulted vista of more than 500 ft., through the nave, the crossing and the choir to the sanctuary. The vaulting of the nave will rise 95 ft. from the floor, and the height of the inner aisles, flanking the nave, will be 45 feet. The nave will consist of nine bays and the choir of five. The plans call for more than 800 statues, some 300 stained

FIG. 4.—PLAN OF THE WASHINGTON CATHEDRAL.

glass windows and more than 1,000 sculptured bosses or keystones of the vaulted arches. The landscape work within the cathedral close combines two distinct elements: (1) that of the cathedral itself and its adjacent buildings, which is in the spirit of old world gardens; (2) that of the wooded slope of Mt. Saint Alban, preserving its natural beauty and increasing its dogwood, laurel, wild azalea and choice undergrowth. Ultimately the cathedral close will contain some 30 auxiliary buildings, harmonizing in design with the central edifice. Among these will be the chapter house, synod hall, cloisters, sacristy, choir rooms and administration

building, the dean's residence, six canons' and six minor canons' residences, 12 retired clergy residences, a library and librarian's residence, a guest house, additional buildings for St. Albans, the National Cathedral School for Boys, and the National Cathedral School for Girls, the College of Preachers and the lodges for the cathedral employees, an amphitheatre, a gymnasium and an athletic field. A stone wall with 12 gates, named after the 12 apostles, will ultimately surround the entire group.

The cathedral of St. John the Divine, on Morningside Heights, New York, when completed, will be third in area among the cathedrals of the world. Founded by the sixth bishop of New York, Bishop Horatio Potter, who obtained a charter to build it in 1873, the cathedral was originally designed by Heins and Le Farge, with a French Romanesque exterior and a Byzantine interior, the first corner stone being laid on St. John's day, 1894. Even during construction efforts were made at a greater unity of style, and the exterior of the choir was made Gothic; and when, in 1917, Dr. Ralph Adams Cram was appointed consulting architect, he reconsidered the whole design and recommended the adoption of French Gothic for both exterior and interior. In its final form St. John the Divine will be a five-aisled structure, three aisles being included within the clerestory walls, the triforium and clerestory being carried, not by the piers of the nave, but over those separating the inner from the outer aisles. The narrow outer aisles take the place of the chain of chapels to be found in most Continental cathedrals. There will be nine bays in the nave, with alternating large and small piers, but the roof vaulting will be in four huge bays, with internal buttressing by means of arches and wing-walls pierced by "roses" across the upper part of the inner side aisles. Owing to the narrowness of the outer aisles there will be no need for external flying buttresses. Externally St. John the Divine will have a central spire, or lantern, and twin west towers.

Other recent churches in the United States which deserve mention are Emmanuel church, Boston, Mass., by Allen and Collens; St. John's, Cambridge, Mass., by Maginnis and Walsh, and St. Bartholomew's, New York, by Goodhue, both Romanesque-Byzantine; the Renaissance Presbyterian church, Madison square, New York, by McKim, Mead and White; the Second Reformed Church, New Brunswick, N.J., by Ludlow and Peabody; and the Tabernacle Presbyterian church, Indianapolis, by J. W. C. Corbuser and R. F. Daggett. Synagogues naturally refer back to their Eastern origin, and the Byzantine Temple Tifereth Israel, Cleveland, O., by Charles R. Greco; Temple Ben Israel, Cincinnati, O., by Tietig and Lee; Temple Emanu-El, San Francisco, Cal., by Bakewell and Brown; and Isaiah temple, Chicago, Ill., by Alfred S. Alschuler, may be quoted as examples. The characteristic form and style of Christian Science churches in America is well illustrated by First Church of Christ, New York, by Carrère and Hastings, and Third Church of Christ, Park avenue, New York, by Delano and Aldrich. In California there have been some interesting experiments in concrete churches, without, however, any very determined attempt—as in France and Germany—to give formal expression to the method of construction, but rather a simplified imitation of bygone styles in the new material. Thus, the church of St. John, by Pierpont and Walter Davis, Wilshire Boulevard church, by Allison and Allison, and St. Paul's cathedral, by Johnson, Kaufman and Coate, all in Los Angeles, are Byzantine, while St. Vincent's church, by Albert C. Martin, in the same city, is in the Baroque of the Spanish mission. (C. M.A.)

In the United States it is quite common to dedicate buildings of all types as memorials to persons or causes. Memorials in the form of monuments of honorary types were erected in great quantities after the Civil War and again by almost every community at the end of the World War of 1914-18. Aside from these which are noteworthy primarily for their quantity, a few distinguished architectural monuments exist. An outstanding example is the Lincoln Memorial at Washington, D.C. (Henry Bacon, architect, 1914-22). Its design combines the dignity of a Greek temple with the grandeur of a landscape setting inspired by the French Renaissance. The Lincoln Memorial has been placed not far from a striking, older memorial, the Washington Monument designed by Robert Mills. The great strength and simplicity of this

simple white marble obelisk 555 ft. high make it a structure ageless in spirit and strong in character. Among the World War memorials, the Liberty Memorial of Kansas City, Mo. (H. van Buren Magonigle, architect) is outstanding for its freedom from the mere application of the classic forms which constituted the vocabulary of architects of that period. Its simple shaft crowned by an urn and flanked by two isolated pavilions on a high terrace, makes a strong impression. A memorial to Thomas Jefferson in the form of a classic, domed structure when undergoing construction in 1938 brought about extended controversy as to the advisability of building another costly monument in the classic style at a period when the spirit for classic revivalism was well passed.

REMAJEN, a town in the Prussian Rhine Province, on the left bank of the Rhine, 12 m. above Bonn, by the railway from Cologne to Coblenz, and at the junction of the railway to Adenau. Pop. (1933) 5,834. Its Roman name was Rigomagus and many Roman remains have been found here. It passed to Prussia from the duchy of Jülich. The (Roman Catholic) parish church is remarkable for a gate dating from the 12th century. Just below the town, on a height overlooking the Rhine, stands the Apollinaris church, built 1899-53 on the site of a chapel formerly dedicated to St. Martin.

REMAINDER, REVERSION. In the view of English law a remainder or reversion is classed either as an incorporeal hereditament, or, with greater correctness, as an estate in expectancy. That is to say, it is a present interest subject to an existing estate in possession called the particular estate, which must determine before the estate in expectancy can become an estate in possession. A remainder or reversion is in strictness confined to real estate, whether legal or equitable, though a similar interest may exist in personality. The particular estate and the remainder or reversion together make up the whole estate over which the grantor has power of disposition. Accordingly a remainder or reversion limited on an estate in fee simple is void. The difference between a remainder and a reversion, stated as simply as possible, is that the latter is that undisposed-of part of the estate which after the determination of the particular estate will fall into the possession of the original grantor or his representative, while a remainder is that part of the estate which under the same circumstances will fall into the possession of a person other than the original grantor or his representative. The subject is too technical for further treatment, for which reference must be made to legal text books.

The State laws of the United States affecting remainders will be found in Washburn, *Real Property*, ii. bk. ii. As a general rule contingent remainders have been rendered of little practical importance by enactments that they shall take effect as executory devices or shall not determine on determination of the particular estate.

REMAINDER THEOREM, a theorem of particular value in the study of polynomials and equations. If we divide

$$2x^3 + 3x^2 + 6 \text{ by } x - 2,$$

for example, the quotient is $2x^2 + 7x + 20$ and the remainder is 20. The remainder, however, can be found by substituting 2 for x in the polynomial. This gives:

$$2 \cdot 2^3 + 3 \cdot 2^2 + 6 = 8 + 6 + 6 = 20.$$

More generally, to find the remainder arising from dividing $f(x)$ by $x - r$, substitute r for x in $f(x)$. This evidently amounts simply to evaluating $f(x)$ for some special value (r) of x . This is conveniently done by following the plan shown at the right. This work reveals not only the remainder (20) but also the coefficients (2+7) of the quotient ($2x+7$). When

$2x^3 + 3x^2 + 6$	$\begin{matrix} 2 \\ 6 \end{matrix}$
$4x^2 + 6x$	$\begin{matrix} 4 \\ 6 \end{matrix}$
$2x + 7$	20

used for this latter purpose it is known as synthetic division. This method of dividing is very helpful in finding the roots of numerical higher equations.

REMAND, a term of English law meaning the return of a prisoner by order of a court to the custody from which he came to the court. Where trials or indictments are not concluded at a single sitting the court of trial has power to remand the accused into proper custody during any necessary adjournment. If the remand is for more than three days the order must be in writing (*Indictable Offences Act 1848*). Similar powers of remand or committal to prison during adjournments are given to justices in the exercise of their summary criminal jurisdiction (*Summary Jurisdiction Acts 1848 and 1879*).

In the case of charges against children or young persons the remand must be to a "place of detention" unless released on bail or certified unfit for such a place of detention (*Children Act 1908*). For this purpose homes have been established under the act.

In the United States the term is used in two senses. The first is where a prisoner is returned to custody to await the resumption of the preliminary hearing or the commencement of the trial. The second is where a cause of action is returned to the original court after the same had been transferred or appealed.

REMBRANDT (1606-1669). **REMBRANDT HARMENS VAN RIJN**, Dutch painter, was born in Leyden on July 15, 1606. It is only within the past 50 years that we have come to know anything of his real history. A tissue of fables formerly represented him as ignorant, boorish and avaricious. These fictions, resting on the loose assertions of Houbraken (*De Grootte Schouburgh*, 1728), have been cleared away by the untiring researches of Scheltema and other Dutchmen, notably by C. Vosmaer, whose elaborate work (*Rembrandt, sa vie et ses oeuvres*, 1868, 2nd ed., 1877) is the basis of our knowledge of the man and of the chronological development of the artist.

Rembrandt was born at No. 3 Weddesteg, on the rampart at Leyden overlooking the Rhine. He was the fourth son of Gerrit Harmens van Rijn, a well-to-do miller. His parents resolved that he should enter a learned profession. With this view he was sent to the Latin School and was enrolled on May 20, 1620, as a student of the University at Leyden, but the boy soon determined to be a painter. Accordingly he was placed for three years under Swaneburgh, an architectural painter trained in Italy. He then went to Peter Lastman in Amsterdam for six months, after which time he returned to Leyden, where he remained from 1626—the date on his earliest picture—to 1631. During the early years of his life at Leyden, Rembrandt seems to have devoted himself entirely to studies, painting and etching the people around him, every picturesque face and form he could get hold of. Life, character, and above all light were the aims of these studies. His mother was a frequent model, and we can trace in her features the strong likeness to her son, especially in the portraits of himself at an advanced age. Eleven portraits of his father are catalogued by Hofstede de Groot. One of his sisters also frequently sat to him. Hofstede de Groot catalogues also 62 existing portraits of himself, most of them painted in youth and in old age.

Rembrandt's earliest pictures were painted at Leyden, from 1627 to 1631. They are chiefly paintings of single figures, as "St. Paul in Prison" and "St. Jerome"; but now and then compositions of several, as "Samson in Prison" and "Presentation in the Temple." The prevailing tone of all these pictures is a greenish grey, the effect being somewhat cold and heavy. The gallery at Cassel gives us a typical example of his studies of the heads of old men, firm in workmanship and full of detail, the effects of light and shade being carefully thought out. His work was now attracting the attention of lovers of art in the great city of Amsterdam; and, urged by their calls, he removed about 1631 to live and die there. At one bound he leaped into the position of the first portrait painter of the city, and received numerous commissions. During the early years of his residence there are many portraits from his hand, firm and solid in manner and staid in expression. The excellent painter Thomas de Keyser was then in the height of his power, and his influence is to be traced in

some of Rembrandt's smaller portraits. Pupils also now flocked to his house in the Bloemgracht, among them Gerard Douw, who was nearly of his own age. The first important work executed by Rembrandt in Amsterdam is "Simon in the Temple," of The Hague museum, a fine early example of his treatment of light and shade and of his subtle colour. The concentrated light falls on the principal figures while the background is full of mystery. The surface is smooth and enamel-like; the action of light on the mantle of Simeon shows how soon he had felt the magical effect of the play of colour. In the life-sized "Lesson in Anatomy" of 1632 we have the first of the great portrait subjects—Tulp the anatomist, the early friend of Rembrandt, discoursing to his seven associates, who are ranged with eager heads round the foreshortened body. The subject had been treated in former years by the Mierevelts, A. Pietersen and others, for the Hall of the Surgeons. But it was reserved for Rembrandt to make it a great picture by the grouping of the expressive portraits and by the completeness of the conception. The colour is quiet and the handling of the brush timid and precise, while the light and shade are somewhat harsh and abrupt. But it is a marvellous picture for a young man of twenty-five, and it is generally accepted as marking a new departure in the career of the painter.

In recent times the number of pictures painted by Rembrandt has been variously estimated. Smith, in his *Catalogue Raisonné* (1836) lists 614 pictures; Bode's *Catalogue* (Paris, 1897, seq.) lists some 550; Wurzbach's *Lexicon* (1910) has about 500; Hofstede de Groot's *Catalogue* (1916) has 988 numbers; and recently J. C. Van Dyke (*Rembrandt and his School*, New York, 1923) has reduced the number of undoubtedly genuine examples painted by the master's own hand to 48. It is impossible here to notice more than the prominent works. Besides the Pellicorne family portraits of 1632, now in the Wallace collection, we have the calligraphist Coppelon of the Cassel gallery, interesting in the first place as an early example of Rembrandt's method of giving permanent interest to a portrait by converting it into a picture. He invests it with a sense of life by a momentary expression as Coppelon raises his head towards the spectator while he is mending a quill. The same motive is to be found in the "Shipbuilder," 1633 (Buckingham Palace), who looks up from his work with a sense of interruption at the approach of his wife. Coppelon was painted and etched by the artist. The two small pictures of "The Philosopher" of the Louvre date from 1633, delicate in execution and full of mysterious effect.

In 1634 Rembrandt married Saskia van Uylenborch, a beautiful, fair-haired Frisian maiden of good connections. Till her death in 1642 she was the centre of his life and art. Saskia brought him a marriage portion of 40,000 guilders. She bore him four children, Rumbartus and two girls, successively named Cornelia after his mother, all of whom died in infancy, and Titus, named after Titia, a sister of Saskia. We have several noble portraits of Saskia, a good type of the beauty of Holland, all painted with the utmost love and care, at Cassel (1633), at Dresden (1641), and a posthumous one (1643) at Berlin.

One of Rembrandt's greatest portraits of 1634 is the superb full-length of Martin Daeu, which, with that of Madame Daeu, painted according to Vosmaer some years later, formed one of the ornaments of the Van Loon collection at Amsterdam. Both now belong to Baron Gustave de Rothschild. From the firm detailed execution of this portrait one turns with wonder to the broader handling of the "Old Woman" (Françoise van Wassenhoven), aged 83, in the National Gallery, of the same year, remarkable for the effect of reflected light and still more for the sympathetic rendering of character.

The life of Samson supplied many subjects in these early days. The "Samson Menacing his Father-in-Law" is forced and violent in its action. One of the prominent examples of Rembrandt's work is the "Marriage of Samson," of the Dresden gallery, painted in 1638. Here Rembrandt gives the rein to his imagination and makes the scene live before us. Except the bride (Saskia), who sits calm and grand on a dais in the centre of the feast, with the full light again playing on her flowing locks and wealth of jewels, all is animated and full of bustle. Samson, evi-

dently a Rembrandt of fantasy, leans over a chair propounding his riddle to the Philistine lords. In execution it is a great advance on former subject pictures; it is bolder in manner, and we have here signs of his approaching love of warmer tones.

The story of Susannah also occupied him in these early years, and he returned to the subject in 1641 and 1653. "The Bather" of the National Gallery may be another interpretation of the same theme. In all of these pictures the woman is coarse in type and lumpy in form, though the modelling is soft and round, the effect which Rembrandt always strove to gain. Beauty of form was outside his art. But the so-called "Danae" (1636) at Leningrad is a sufficient reply to those who deny his ability ever to appreciate the beauty of the nude female form. It glows with colour and life, and the blood seems to pulsate under the warm skin. In the picturesque story of Tobit Rembrandt found much to interest him, as we see in the beautiful small picture of the d'Arenberg Collection at Brussels. Slight is being restored to the aged Tobias, while with infinite tenderness his wife holds the old man's hand caressingly. In the Berlin gallery he paints the anxiety of the parents as they wait for the return of their son. In 1637 he painted the fine picture now in the Louvre of the "Flight of the Angel." Reverence and awe are shown in every attitude of the Tobit family. A similar lofty treatment is to be found in the "Christ as the Gardener," appearing to Mary, of 1638 (Buckingham Palace).

We have now arrived at the year 1640, the threshold of his second manner, which extended to 1654, the middle age of Rembrandt. During the latter part of the previous decade we find the shadows more transparent and the blending of light and shade more perfect. There is a growing power in every part of his art. The coldness of his first manner had disappeared, and the tones were gradually changing into golden-brown. He had attained to a truer, calmer form of dramatic expression, of which the "Moses" of Dresden is a good example (1641). The portraits painted "to order" became more rare about this time, and those which he gave to his chief friends of his circle, such as the "Mennonite Preacher" (C. C. Ansoo) and the "Gilder," a fine example of his golden tone, in the Havemeyer collection, New York. His own splendid portrait (1640) in the National Gallery illustrates the change in his work. It describes the man well—strong and robust, with powerful head, firm and compressed lips and determined chin, with heavy eyebrows, separated by a deep vertical furrow, and with eyes of keen penetrating glance—altogether a self-reliant man. He has now many friends and pupils, and numerous commissions, even from the stadtholder; he has bought a large house in the Breedstraat, in which during the next 16 years of his life he gathers his large collection of paintings, engravings, armour and costume which figure afterwards in his inventory. His taste was wide and his purchases large, for he was joint owner with picture-dealers of paintings by Giorgione and Palma Vecchio, while for a high-priced Marcantonio Ramondi print he gave in exchange a fine impression of his "Healing the Sick," which has since been known as the "Hundred Guilders Print." The stadtholder was not a prompt payer, and an interesting correspondence took place between Rembrandt and Constantijn Huygens, the poet and secretary of the prince. The Rembrandt letters which have come down to us are few, and these are therefore of importance. Rembrandt puts a high value on the picture, which he says had been painted "with much care and zeal," but he is willing to take what the prince thinks proper; while to Huygens he sends a large picture as a present for his trouble in carrying through the business. There is here no sign of the grasping greed with which he has been charged, while his unselfish conduct is seen in the settlement of the family affairs at the death of his mother in 1640.

The year 1642 is remarkable for the great picture formerly known as the "Night Watch," but now more correctly as the "Sortie of the Banning Cock Company," in which 29 life-sized civic guards are introduced issuing pell-mell from their clubhouse. Such guilds of arquebusers had been painted admirably before by Ravesteyn and notably by Frans Hals, but Rembrandt determined to throw life and animation into the scene. The domi-

nant colour is the citron yellow uniform of the lieutenant, wearing a blue sash, while a Titian-like red dress of a musketeer, the black velvet dress of the captain, and the varied green of the girl and drummer, all produce a rich and harmonious effect. The background has become dark and heavy, and the scutcheon on which the names are painted is scarcely to be seen.

But this year of great achievement was also the year of his great loss, for Saskia died in 1642, leaving Rembrandt her sole trustee for her son Titus, but with full use of the money till he should marry again or till the marriage of Titus. The words of the will express her confidence in her husband. With her death his life was changed. There is a pathetic sadness in his pictures of the Holy Family—a favourite subject at this period of his life. All of these he treats with the naïve simplicity of Reformed Holland, giving us the real carpenter's shop and the mother watching over the Infant reverently and lovingly, with a fine union of realism and idealism.

The street in which he lived was full of Dutch and Portuguese Jews, and many a Jewish rabbi sat to him. He accepted or invented their turbans and local dress as characteristic of the people. But in his religious pictures it is not the costume we look at; what strikes us is the profound perception of the sentiment of the story, making them true to all time and independent of local circumstance. A notable example of this feeling is to be found in the "Woman Taken in Adultery" of the National Gallery, painted in 1644 in the manner of the "Simeon" of The Hague. It commands our attention from the grand conception of the painter who has invested Christ with majestic dignity. A similar lofty ideal is to be found in his various renderings of the "Pilgrims at Emmaus," notably in the Louvre picture of 1648. From the same year we have the "Good Samaritan" of the Louvre, the story of which is told with intense pathos. The helpless suffering of the wounded man, the curiosity of the boy on pike, the excited faces at the upper window, are all conveyed with mastery skill. In these last two pictures we find a broader touch and freer handling, while the tones pass into a dull yellow and brown with a predilection for a note of deep rich red.

Rembrandt touched no side of art without setting his mark on it, whether in still life, as in his dead birds or the "Slaughtered Ox" of the Louvre (with its repetitions at Glasgow and Budapest), or in his drawings of elephants and lions, all of which are instinct with life. But at this period of his career we come upon a branch of his art on which he left, both in etching and in painting, the stamp of his genius, viz., landscape. Roeland Roffman, but ten years his senior, evidently influenced his style, for the resemblance between their works is so great that, as at Cassel, there has been confusion of authorship. Hercules Seghers also was much appreciated by Rembrandt, for at his sale eight pictures by this master figure in the inventory, and Vosmaer discovered that Rembrandt had worked on a plate by Seghers and had added figures to an etched "Flight into Egypt." The earliest pure landscape known to us from Rembrandt's hand is that at the Rijks museum (1637-38), followed in the latter year by those at Brunswick, Boston (U.S.A.) and "The River Scene," formerly in the collection of Marcus Kapfel, Berlin. Better known is the "Winter Scene" of Cassel (1646), silvery and delicate. As a rule in his painted landscape he aims at grandeur and poetical effect, as in the "Repose of the Holy Family" of 1647 in the National Gallery, Dublin, a moonlight effect, clear even in the shadows. The "Canal" in the Rijks museum, Amsterdam, is also conceived in this spirit. A similar poetical vein runs through the "Landscape with Ruins" of Cassel, in which the beams of the setting sun strike on the ruins while the valley is sunk in the shades of approaching night. More powerful still is the weird effect of the "Windmill," with its glow of light and darkening shadows. In all these pictures light with its magical influences is the theme of the poet-painter. From the number of landscapes by himself in the inventory of his sale, it would appear that these grand works were not appreciated by his contemporaries. The last of the landscape series dates from 1655 or 1656, the close of the middle age or manhood of Rembrandt, a period of splendid power. In the "Joseph Accused by Potiphar's Wife" of 1655 we have great dramatic vigour and

perfect mastery of expression, while the brilliant colour and glowing effect of light and shade attest his strength. To this period also belongs the great portrait of himself in the Fitzwilliam museum at Cambridge.

But evil days were at hand. The long-continued wars and civil troubles had worn out the country, and money was scarce; and we find Rembrandt borrowing considerable sums of money on the security of his house. Then, in this year of 1654, we find him involved in the scandal of having a child by his servant Hendrickje Jagers or Stoffels, as appears by the books of the Reformed Church at Amsterdam. He recognized the child and gave it the name of Cornelia, after his mother, but there is no proof that he married Hendrickje, who seems to have continued to live with him, for we find her claiming a chest as her property at his sale in 1658.

The beautiful portrait of the "Lady" in the Salon Carré of the Louvre and the "Venus and Cupid" of the same gallery may represent Hendrickje and her child. Both pictures belong to this date, and by their treatment are removed from the category of Rembrandt's usual portraits. But if this is conjecture, we get nearer to fact when we look at the picture to which tradition has attached the name of "Rembrandt's Mistress," now in the Edinburgh National Gallery. At a glance one can see that it is not the mere head of a model, as she lies in bed raising herself to put aside a curtain. In 1654 he painted the famous "Portrait of Jan Six," the future burgomaster, consummate in its ease and character, as Six descends the steps of his house drawing on his glove. The connection between Rembrandt and the great family of Six was long and close. In 1641 the mother of Six, Anna Wymer, had been painted with consummate skill by Rembrandt, who also executed in 1647 the beautiful etching of Six standing by a window reading his tragedy of *Medea*; afterwards illustrated by Rembrandt. Now he paints his portrait in the prime of manhood. In 1656 Rembrandt's financial affairs became more involved, and the Orphan's Chamber transferred the house and ground to Titus, though Rembrandt was still allowed to take charge of Saskia's estate. Nothing, however, could avert the ruin of the painter, who was declared bankrupt in July 1656, an inventory of all his property being ordered by the Insolvent Chamber. The first sale took place in 1657 in the Keizerskroon hotel; and the second in 1658, when the larger part of the etchings and drawings were disposed of—"collected by Rembrandt himself with much love and care," says the catalogue. The sum realized, under 5,000 guilders, was but a fraction of their value. Driven thus from his house, stripped of everything he possessed, even to his table linen, Rembrandt took a modest lodging in the Keizerskroon hostelry (the amounts of his bills are on record), apparently without friends and thrown entirely on himself.

But this dark year of 1656 stands out prominently as one in which some of his greatest works were produced, as, for example, "Jacob blessing the Sons of Joseph" of the Cassel Gallery, and "John the Baptist Preaching" of the Berlin gallery, though this picture is sometimes ascribed to an earlier period of about 1635. Instead of the brilliancy of 1654 we have for two or three years a preference for dull yellows, reds and greys, with a certain uniformity of tone. The handling is broad and rapid. There is less carressing of colour for its own sake, even less straining after vigorous effect of light and shade. To the same year belongs the "Lesson in Anatomy of Johann Deyman" in the museum at Amsterdam. The subject is similar to the great Tulp of 1632, but his manner and power of colour had advanced so much that Sir Joshua Reynolds, on his visit to Holland in 1781, was reminded by it of Michelangelo and Titian. The same period gives us the "Adoration of the Magi" of Buckingham Palace.

After the sale of the house in the Breedstraat, Rembrandt retired to the Rosengracht, an obscure quarter at the west end of the city. We are now drawing to the splendid close of his career in his third manner, in which his touch became broader, his impasto more solid and his knowledge more complete. We may mention the "Old Man with the Grey Beard" of the National Gallery (1657) leading up to the great portraits of the "Syndics of the Cloth Hall" of 1661.

In his old age Rembrandt continued to paint his own portrait as assiduously as in his youthful days. Fine examples are in the Louvre, in the National Gallery, London, and in the Frick collection, New York. All show the same self-reliant expression, though broken down by age and the cares of a hard life.

About the year 1668, Rembrandt painted the (so-called) "Jewish Bride" of the Rijks museum in Amsterdam, and the "Family Group" of Brunswick, the last and perhaps the most brilliant works of his life, bold and rapid in execution and marvellous in the subtle mixture and play of colours in which he seems to revel.

In 1668 Titus, the only son of Rembrandt, died, leaving one child, and on Oct. 4, 1669, the great painter himself passed away, leaving two children, and was buried in the Wester Kerk. He had outlived his popularity, for his manner of painting was no longer in favour with a people who preferred the smooth trivialities of Van der Werf and the younger Mieris.

We must give but a short notice of Rembrandt's achievements in etching. Here he stands out by universal confession as first in his unrivalled technical skill, his mastery of expression and the lofty conceptions of many of his great pieces, as in the "Death of the Virgin," the "Christ Preaching," the "Christ Healing the Sick" (the "Hundred Guilder Print"), the "Presentation to the People," the "Crucifixion" and others. So great is his skill simply as an etcher that one is apt to overlook the nobleness of the etcher's idiom, and this tendency has been doubtless confirmed by the enormous difference in money value between "states" of the same plate, rarity giving in many cases a factitious worth in the eyes of collectors. The points of difference between these states arise from the additions and changes made by Rembrandt on the plate; and the prints taken off by him have been subjected to the closest inspection by Bartsch, Gersaint, Wilson, Daubly, De Clausen, C. Blanc, Seymour Haden, Middleton, Dutuit, Rovinski, Singer, Hind and lately by J. C. Van Dyke and Coppley, who have described them, and to whom the reader is referred. The classification of Rembrandt's etchings adopted till lately was according to the subject, as biblical, portrait, landscape, and so on; until Vosmaer attempted the more scientific and interesting one of chronology. This method has been developed by Sir F. Seymour Haden and Middleton.

The great period of his etching lies between 1639 and 1661, after which the old painter seems to have renounced the needle. In these 20 years were produced his greatest works in portraiture, landscape and Bible story. They bear the impress of the genius of the man. Rembrandt's drawings are done almost exclusively in pen and wash, though he used red and black chalk sometimes in his early period. His line, apparently haphazard, is extremely suggestive, expressive and sure, and by a few strokes of the pen he suggests scenes full of life and feeling. The publication *Original Drawings by Rembrandt* (1888-1906) was issued in three series of eight volumes. The first series, with 200 drawings edited by F. Lippmann with the help of Bode, Colvin, Seymour Haden and Heseltine, contains the best drawings. The following two series completed by Hofstede de Groot contain many doubtful pieces. Recently attempts have been made to distinguish the master's work from that of his pupils by W. R. Valentiner and by J. C. Van Dyke (*the Rembrandt Drawings and Etchings*, New York, 1927). But agreement has not been reached.

For bibliography and general see: C. Vosmaer, *Rembrandt* (2nd ed., The Hague, 1897); W. Bode, *Studien zur Geschichte der Holländischen Malerei* (Brunswick, 1883); E. Michel, *Rembrandt* (Paris, 1893); London, 1906); W. Bode and C. H. de Groot, *Rembrandt complete work* 3 vols. (1897-1906); W. Bode, *Rembrandt und seine Zeitgenossen* (Leipzig, 1906); C. H. de Groot, *Die Urkunden* (The Hague, 1905); J. Baldwin Brown, *Rembrandt* (1907); W. R. Valentiner, *Rembrandt und seine Umgebung* (Stasbourg, 1905).

For reproductions of Rembrandt's work see: the monumental folios compiled by Dr. Bode, in smaller form the volume on Rembrandt in the series *Klassiker der Kunst* (3rd ed. by Dr. Valentiner, Stuttgart, 1908) with a supplementary volume of recently discovered Rembrandts issued in 1921; and the volumes of Rembrandt's etchings compiled by H. W. Singer (1906) and of Rembrandt's drawings compiled by W. R. Valentiner (1924-) in the same series; and the volumes of Rembrandt's etchings arranged by A. M. Hind (1912 and 1923).

For appreciations of Rembrandt's work see E. Fromentin, *Maîtres d'autrefois* (1904); D. Langbehn, *Rembrandt als Erzieher* (Leipzig, 1890); P. G. Hamerton, *Rembrandt's Etchings* (1894); W. Weisbach, *Rembrandt* (1926). (J. F. W.)

REMEMBRANCER, the name of certain officials who compiled the memoranda rolls and prepared the business for the barons of the exchequer, and so "reminded" them of the matter with which they must deal. There were at one time three clerks of the remembrance, styled king's remembrancer, lord treasurer's remembrancer and remembrancer of first-fruits. The latter two offices have become extinct. At the present moment (1929) the King's remembrancer is required to be a master of the court of exchequer, and by the Supreme Court of Judicature (Officers) Act, 1879, he is a master of the supreme court. The office is usually filled by the senior master. The king's remembrancer still assists at certain ceremonial functions. His duties are set out in the *Second Report of the Legal Departments Commission* (1874).

"Remembrancer" is also the title of an official of the corporation of the City of London, whose principal duty is to represent that body before parliamentary committees and at council and treasury boards.

REMIGIUS, ST. (c. 437-533), bishop of Reims and the friend of Clovis, whom he converted to Christianity. According to Gregory of Tours, 3,000 Franks were baptized with Clovis by Remigius on Christmas Day, 496, after the defeat of the Alamanni. A good many fictions grew up around his name, e.g., that he anointed Clovis with oil from the sacred ampulla, and that Pope Hormisdas had recognized him as primate of France. The *Commentary on the Pauline Epistles* (ed. Villalpandus, 1699) is not his work, but that of Remigius of Auxerre.

For authorities see H. Jadart, *Bibliographie des ouvrages conc. la vie et le culte de S. Remi* (Reims, 1891).

REMINGTON, FREDERIC (1861-1909), American artist, was born at Canton (N.Y.), on Oct. 4, 1861. He was a pupil of the Yale Art School, and of the Art Students' League, New York, and became known as an illustrator, painter and sculptor. Having spent much time in the West, where he went for his health, and having been with the United States troops in actual warfare, he made a specialty of rendering the North American Indian and the United States soldier as seen on the western plains. In the Spanish-American War he was with the army under General Shafter as war correspondent. He died Dec. 26, 1909, near Ridgefield (Conn.). His statuesque of soldiers, Indians, cowboys and trappers are full of character, while his paintings have been largely reproduced. He wrote several volumes of stories, including *Pony Tracks* (1895), *Crooked Trails* (1898), *Sundown Lefare* (1899), and *John Ermine of the Yellowstone* (1902).

REMIREMONT, a town of eastern France, in the department of Vosges, 17 m. S.E. of Épinal by rail, on the Moselle, below its confluence with the Moselotte. Pop. (1936) 10,242. Remiremont (*Romarchi Mons*) is named after St. Romaric, a companion of St. Columban of Luxeuil, who in the 7th century founded a monastery and a convent on the hills above the present town. In 910 an invasion of the Hungarians drove the nuns to Remiremont, which had grown round a villa of the Frankish kings, and in the 11th century they settled there. Enriched by dukes of Lorraine, kings of France and emperors of Germany, the ladies of Remiremont attained great power. The abbess was a princess of the empire, and received consecration at the hands of the pope. The fifty canonesses were selected from the nobility. On Whit-Monday the neighbouring nobles paid homage to the chapter in a ceremony called the "Kyselade"; and on St. Michael's the dukes of Lorraine, the imperial successors of the abbess, had to come to Remiremont to swear to confirm their protection. The "War of the Succession" (P. 1000-1005) in 1566 between the duke and the abbess ended in favour of the duke and terminated the abbess's power. The monastery and nuns were both suppressed in the Revolution. Remiremont is surrounded by forested mountains. The 15th cent. abbey church has a crypt of the 11th century. The abbatial residence (which now contains the *mairie*, the court-house and the public library) has been twice rebuilt in the original plan in modern times. Some of the houses of the canonesses (17th and 18th centuries) remain. Remire-

mont has a board of trade-arbitrators and a chamber of arts and manufactures. Its industries include cotton-spinning and weaving, the manufacture of embroidery, iron and copper founding and the manufacture of brushes.

REMIZOV, ALEXEI (1877-), Russian novelist, was born June 24, 1877, in Moscow and brought up amid factory surroundings and in the strict observance of Orthodox Church rites, with frequent pilgrimages to monasteries. He thus gained an intimate knowledge of national habits, monastic life and old religious legends. He studied natural science and economics at Moscow University, took part in revolutionary activities, and was imprisoned and spent years of exile in Vologda. He subsequently went to live in Paris. The influences of his varying surroundings contributed to the formation of his unique fantastic personality, uniting the whimsical mischievousness of some fairy-tale sprite with a deep spirit of pity. His literary life dates from 1902; from that time until 1920 he published 36 volumes of fiction: novels, tales, short stories and fairy-tales, miracle plays, etc.

The most remarkable of Remizov's works are *The Pond* (1905), a powerful and gloomy picture of vulgarity, vice and crime among the Moscow bourgeoisie and the monasteries; *The Clock* (1908, Eng. trans. 1924); *The Fifth Pestilence*, two stories of provincial life (Eng. trans. by A. Brown 1927); *The Sisters of the Cross* (1910), a novel of St. Petersburg life; also *The Cockerel* and stories relating to the revolution of 1905, and several plays.

REMONSTRANTS, the name given to those Dutch Protestants who, after the death of Arminius (q.v.), maintained the views associated with his name, and in 1610 presented to the states of Holland and Friesland a "remonstrance" in five articles formulating their points of departure from stricter Calvinism. These were: (1) that the divine decree of predestination is conditional, not absolute; (2) that the Atonement is in intention universal; (3) that man cannot of himself exercise a saving faith; (4) that though the grace of God is a necessary condition of human effort it does not act irresistibly in man; (5) that believers are able to resist sin but are not beyond the possibility of falling from grace. The Remonstrants were assailed both by personal enemies and by the political weapons of Maurice of Orange, who executed and imprisoned their leaders for holding republican views. In 1618-19 the synod of Dort (see Dort, Synod of), from which the thirteen Arminian pastors headed by Simon Episcopius (q.v.) were shut out, established the victory of the Calvinist school. The judgment of the synod was enforced by the deposition and in some cases the banishment of Remonstrant ministers; but the government soon became convinced that their party was not dangerous to the state, and in 1630 they were formally allowed liberty to reside in all parts of Holland and build churches and schools. Henceforth, however, their importance was more theological than ecclesiastical; and their liberal school of theology, which naturally grew more liberal and even rationalistic, has reacted powerfully on the state church and on other Christian denominations.

REMORA or **SUCKING-FISH**, a name given to fishes of the family Echenideidae, remarkable for having the spinous dorsal fin transformed into a transversely laminated suctorial disc, placed on top of the head. There are about a dozen species from warm seas; they attach themselves to sharks, turtles, and large fish, and are transported by them, but they detach themselves and swim when searching for food.

REMPHAN (in A.V., *Rephan* in R.V.) a word found in Acts vii. 43 ("Παρά, Westcott and Hort). The writer is quoting the Septuagint of Amos v. 26 ("Παρά"), where the Hebrew has *Kayyan* (קַיָּאן). This is probably a mistake for *Kewan*, the Babylonian name for the planet Saturn. The Greek form may be an error of the transliterator.

REMSCHIED, a town in the Prussian Rhine Province, Germany, 6 mi. by rail S. of Barmen, in an industrial area heavily bombed in World War II. Pop. (1939) 103,437. It is a centre of the hardware industry, and makes large quantities of tools, scythes, drills and other small articles in iron, steel and brass.

REMSEN, IRA (1846-1927), American chemist, was born in New York city on Feb. 10, 1846, and educated at the College

of the City of New York (B.A., 1865), College of Physicians and Surgeons (Columbia—M.D., 1867) and at the Universities of Munich and Göttingen (Ph.D., 1870). He spent the two years 1870-72 at the University of Tübingen as assistant to Fittig and here began the investigations into pure chemistry upon which his later fame was chiefly based. He was professor of chemistry at Williams College in 1872-76 and in 1876 was one of the original faculty of the new Johns Hopkins University. Here he was professor of chemistry 1876-1913, director of the chemical laboratory 1876-1908, secretary of the Academic Council 1881-1901 and president of the university 1901-1913. He was president emeritus and professor emeritus 1913-1927, during which time he travelled widely and worked on government pure food commissions. He brought to Johns Hopkins many of the German laboratory methods and as a teacher he soon became famous. A long series of students trained in intimate association with him became widely scattered and influential. He founded the *American Chemical Journal* in 1879 and continued to edit it almost to the time of his death. In it most of his scientific papers were published. In the first volume he described the preparation and properties of a new compound, subsequently to become widely known as saccharine, which he and a pupil discovered. Another long series of studies led to the discovery and enunciation of Remsen's law. He also became widely known for his series of text-books, *Principles of Theoretical Chemistry* (1876) passing through five editions and being translated into German, Russian and Italian. Others of like popularity were *An Introduction to the Study of the Compounds of Carbon* (1885; 5th rev., 1922); *Elements of Chemistry* (1888); *Inorganic Chemistry* (1889); *A College Text-book of Chemistry* (1908). Remsen died at Carmel, Cal., on Mar. 5, 1927.

See B. Hazzow, *Eminent Chemists of Our Time* (1920); "Impressions of Ira Remsen," in *Johns Hopkins Alumni Magazine*, vol. xvi. pp. 215-226 (1928); "Ira Remsen" in *Science*, N.S. vol. lxvi. (1927), pp. 243-246.

RÉMUSAT, CHARLES FRANÇOIS MARIE, COMTE DE (1797-1875), French politician and man of letters, was born in Paris on March 13, 1797. He was called to the bar, and became an active journalist. He signed the journalists' protest against the Ordinances of July 1830, and in October was elected deputy for Haute Garonne. He then ranked himself with the *doctrinaires*, and supported measures of restriction on popular liberty.

Rémusat held office under Thiers in the reign of Louis Philippe. He took no part in politics under the Empire until 1869. In Aug. 1871 he succeeded Favre as minister of foreign affairs. He died in Paris on Jan. 6, 1875.

His works include: *Abélard* (2 vols., 1845); *Saint Anselme de Cantorbéry* (1854); *L'Angleterre au XVIII^e siècle* in 1856 (2nd ed. enlarged, 1865); *Bacon, sa vie, son temps, etc.* (1858); *Channing, sa vie et ses œuvres* (1862); *John Wesley* (1870); *Lord Herbert de Cherbury* (1874) *Histoire de la philosophie en Angleterre depuis Bacon jusqu'à Locke* (1875).

RÉMUSAT, JEAN PIERRE ABEL (1788-1832), French Chinese scholar, was born in Paris on Sept. 5, 1788. He was educated for the medical profession, but a Chinese herbal in the collection of the Abbé Tersan led him to study Chinese. His *Essai sur la langue et la littérature chinoises* (1811) won him the patronage of Silvestre de Sacy, and in 1814 he was appointed to the chair of Chinese founded in that year at the Collège de France. His contributions from Chinese sources to the history of the Tatar nations claims special notice. Rémusat became an editor of the *Journal des savants* in 1818, and founder and first secretary of the Paris Asiatic Society in 1822; he also held various Government appointments. He died at Paris on June 4, 1832. A list of his works is given in Quéard's *France littéraire* s.v. Rémusat.

RENAISSANCE, THE. The "Renaissance" or "Renaissance" is a term used to indicate a well-known but indefinite space of time and a certain phase in the development of Europe. On the one hand it denotes the transition from that period of history which we call the middle ages (*q.v.*) to that which we call modern. On the other hand it implies those changes in the intellectual and moral attitude of the Western nations by which the transition was characterized. If we insist upon the literal and etymological meaning of the word, the Renaissance was the re-birth;

and it is needful to inquire of what it was the re-birth. The metaphor of Renaissance may signify the entrance of the European nations upon a fresh stage of vital energy in general, implying a fuller consciousness and a freer exercise of faculties than had belonged to the mediæval period. Or it may mean the resuscitation of simply intellectual activities, stimulated by the revival of antique learning and its application to the arts and literatures of modern peoples. Upon our choice between these two interpretations of the word depend important differences in any treatment of the subject. The former has the disadvantage of making it difficult to separate the Renaissance from other historical phases—the Reformation for example—with which it ought not to be confounded. The latter has the merit of assigning a specific name to a limited series of events and group of facts, which can be distinguished for the purpose of analysis from other events and facts with which they are intimately but not indissolubly connected. In other words, the one definition of Renaissance makes it denote the whole change which came over Europe at the close of the middle ages. The other confines it to what was known by our ancestors as the Revival of Learning. Yet, when we concentrate attention on the recovery of antique culture, we become aware that this was only one phenomenon or symptom of a far wider and more comprehensive alteration in the conditions of the European races. We find it needful to retain both terms, Renaissance and Revival of Learning, and to show the relations between the series of events and facts which they severally imply. The Revival of Learning must be regarded as a function of that vital energy, an organ of that mental evolution, which brought into existence the modern world, with its new conceptions of philosophy and religion, its re-awakened arts and sciences, its firmer grasp on the realities of human nature and the world, its manifold inventions and discoveries, its altered political systems, its expansive and progressive forces. Important as the Revival of Learning undoubtedly was, there are essential factors in the complex called the Renaissance with which it can but remotely be connected. When we analyse the whole group of phenomena which have to be considered, we perceive that some of the most essential have nothing or little to do with the recovery of the classics. These are, briefly speaking, the decay of those great fabrics, church and empire, which ruled the middle ages both as ideas and as realities; the development of nationalities and languages; the enfeeblement of the feudal system throughout Europe; the invention and application of paper, the mariner's compass, gunpowder, and printing; the exploration of continents beyond the ocean; and the substitution of the Copernican for the Ptolemaic system of astronomy. Europe in fact had been prepared for a thorough-going metamorphosis before that new idea of human life and culture which the Revival of Learning brought to light had been made manifest. It had recovered from the confusion consequent upon the dissolution of the ancient Roman empire. The Teutonic tribes had been Christianized, civilized and assimilated to the previously Latinized races over whom they exercised the authority of conquerors. Comparative tranquillity and material comfort had succeeded to discord and rough living. Modern nationalities, defined as separate factors in a common system, were ready to co-operate upon the basis of European federation. The ideas of universal monarchy and of indivisible Christendom, incorporated in the Holy Roman empire and the Roman Church, had so far lost their hold that scope was offered for the introduction of new theories both of state and church which would have seemed visionary or impious to the mediæval mind. It is, therefore, obvious that some term, wider than Revival of Learning, descriptive of the change which began to pass over Europe in the 14th and 15th centuries, has to be adopted. That of Renaissance, Rinascimento, or Renaissance is sufficient for the purpose, though we have to guard against the tyranny of what is after all a metaphor. We must not suffer it to lead us into rhetoric about the deadness and the darkness of the middle ages, or hamper our inquiry with preconceived assumptions that the re-birth in question was in any true sense a return to the irrecoverable pagan past. Nor must we imagine that there was any abrupt break with the middle ages. On the contrary, the Renaissance was rather the last stage of the middle ages emerging

from ecclesiastical and feudal despotism, developing what was original in mediaeval ideas by the light of classic arts and letters, holding in itself the promise of the modern world. It was, therefore, a period and a process of transition, fusion, preparation, tentative endeavour. And just at this point the real importance of the Revival of Learning may be indicated. That rediscovery of the classic past restored the confidence in their own faculties to men striving after spiritual freedom; revealed the continuity of history and the identity of human nature in spite of diverse creeds and different customs; held up for emulation master-works of literature, philosophy and art; provoked inquiry; encouraged criticism; shattered the narrow mental barriers imposed by mediaeval orthodoxy. Humanism, a word which will often recur in the ensuing paragraphs, denotes a specific bias which the forces liberated in the Renaissance took from contact with the ancient world—the particular form assumed by human self-esteem at that epoch—the ideal of life and civilization evolved by the modern nations. It indicates the endeavour of man to reconstitute himself as a free being, not as the thrall of theological despotism, and the peculiar assistance he derived in this effort from Greek and Roman literature, the *litterae humaniores*, letters leaning rather to the side of man than of divinity.

In this article the Renaissance will be considered as implying a comprehensive movement of the European intellect and will toward self-emancipation, toward reassertion of the natural rights of the reason and the senses, toward the conquest of this planet as a place of human occupation, and toward the formation of regulative theories both for states and individuals differing from those of mediaeval times. The Revival of Learning will be treated as a decisive factor in this process of evolution on a new plan. To exclude the Reformation and the Counter-Reformation wholly from the survey is impossible. These terms indicate moments in the whole process of modern history which were opposed, each to the other, and both to the Renaissance; and it is needful to bear in mind that they have, scientifically speaking, a quite separate existence. Yet, if the history of Europe in the 16th century of our era came to be written with the brevity with which we write the history of Europe in the 6th century B.C., it would be difficult at the distance of time implied by that supposition to distinguish the Italian movement of the Renaissance in its origin from the German movement of the Reformation. Both would be seen to have a common starting-point in the reaction against long dominant ideas which were becoming obsolete, and also in the excitation of faculties which had during the same period been accumulating energy.

Chronology.—The Renaissance, if we try to regard it as a period, was essentially the transition from one historical stage to another. It cannot therefore be confined within strict chronological limits. There is one date, however, which may be remembered with advantage as the starting-point in time of the Renaissance, after the departure from the middle ages had been definitely and consciously made by the Italians. This is the year 1453, when Constantinople, chosen for his capital by the first Christian emperor of Rome, fell into the hands of the Turk.¹ One of the survivals of the old world, the shadow of what had been the Eastern empire, now passed suddenly away. Almost at the same date that visionary revival of the Western empire, which had imposed for six centuries upon the imagination of mediaeval Europe, hampering Italy and impeding the consolidation of Germany, ceased to reckon among political actualities; while its more robust rival, the Roman Church, seemed likely to sink into the rank of a petty Italian principality. It was demonstrated by the destruction of the Eastern and the dotage of the Western empire and by the new papal policy which Nicholas V. inaugurated, that the old order of society was about to be superseded. Nothing remained to check those centrifugal forces in state and church which substituted a confederation of rival European Powers for the earlier ideal of "To the humanists themselves "humanitas" meant nothing more nor less than "culture."

¹Most scholars now deny that the fall of Constantinople had any appreciable influence on the culture of Western Europe. For Symonds' date of 1453 they would substitute the date of the invention of printing about 1440.

universal monarchy, and separate religious constitutions for the previous Catholic unity. At the same time the new learning introduced by the earlier humanists awakened free thought, encouraged curiosity, and prepared the best minds of Europe for speculative audacities from which the schoolmen would have shrunk, and which soon expressed themselves in acts of cosmopolitan importance. If we look a little forward to the years 1492-1500, we obtain a second date of great importance. In these years the expedition of Charles VIII. to Naples opened Italy to French, Spanish and German interference. The leading nations of Europe began to compete for the prize of the peninsula, and learned meanwhile that culture which the Italians had perfected. In these years the secularization of the papacy was carried to its final point by Alexander VI., and the Reformation became inevitable. The same period was marked by the discovery of America, the exploration of the Indian seas, and the consolidation of the Spanish nationality. It also witnessed the application of printing to the diffusion of knowledge. Thus, speaking roughly, the half-century between 1450 and 1500 may be termed the culminating point of the Renaissance. The transition of the mediaeval to the modern order was now secured if not accomplished, and a rubicon had been crossed from which no retrogression to the past was possible. Looking yet a little farther to the years 1527 and 1530 a third decisive date is reached. In the first of these years happened the sack of Rome, in the second the pacification of Italy by Charles V. under a Spanish hegemony. The age of the Renaissance was now closed for the land which gave it birth. The Reformation had taken firm hold on northern Europe. The Counter-Reformation was already imminent.

THE MIDDLE AGES

It must not be imagined that so great a change as that implied by the Renaissance was accomplished without premonitory symptoms and previous endeavours. In the main we mean by it the recovery of freedom for the human spirit after a long period of bondage to oppressive ecclesiastical and political orthodoxy—a return to the liberal and practical conceptions of the world which the nations of antiquity had enjoyed, but upon a new and enlarged platform. This being so, it was inevitable that the finally successful efforts after self-emancipation should have been anticipated from time to time by strivings within the ages that are known as dark and mediaeval. It is, therefore part of the present inquiry to pass in review some of the claimants to be considered precursors to the Renaissance.

First of all must be named the Frank in whose lifetime the dual conception of universal empire and universal church, divinely appointed sacred and inviolable, began to control the order of European society. Charles the Great (Charlemagne) lent his forces to the plan of resuscitating the Roman empire at a moment when his own power made him the arbiter of Western Europe, when the papacy needed his alliance, and when the Eastern empire had passed under the usurped regency of a female. He modelled an empire, Roman in name, but essentially Teutonic, since it owed such substance as its fabric possessed to Frankish armies and the swards of the German people. As a structure composed of divers ill-connected parts it fell to pieces at its builder's death, leaving little but the incubus of a memory, the fascination of a mighty name, to dominate the mind of mediaeval Europe. As an idea, the Empire grew in visionary power, and remained one of the chief obstacles in the way of both Italian and German national coherence. Real force was not in it, but rather in that counterpart to its unlimited pretensions, the Church which had evolved it from barbarian night, and which used her own more vital energies for undermining the rival of her creation. Charles the Great, having proclaimed himself successor of the Caesars, was obscurely ambitious of imitating the Augusti also in the sphere of letters. He caused a scheme of humanistic education to be formulated, and gave employment at his court to rhetoricians of whom Alcuin was the most considerable. But very little came of the Revival of Learning which Charles is supposed to have encouraged; and the empire he restored was accepted by the mediaeval intellect in a crude theological and vaguely mystical spirit. We should, how-

ever, here remember that the study of Roman law, which was one important precursory symptom of the Renaissance, owed much to mediæval respect for the empire as a divine institution. This, together with the municipal Italian intolerance of the Lombard and Frankish codes, kept alive the practice and revived the science of Latin jurisprudence at an early period.

Speculation and Heresy.—Philosophy had tried to free itself from the trammels of theological orthodoxy in the hardy speculations of some schoolmen, notably of Scotus Erigena and Abelard. These innovators found, however, small support, and were defeated by opponents who used the same logical weapons with authority to back them. Nor were the rationalistic opinions of the Averroists without their value, though the Church condemned these deviators from her discipline as heretics. Such mediæval materialists, moreover, had but feeble hold upon the substance of real knowledge. Imperfect acquaintance with authors whom they had studied in Latin translations made by Jews from Arabic commentaries on Greek texts, together with almost total ignorance of natural laws, condemned them to sterility. Like the other scholasticists of their epoch, they fought with phantoms in a visionary realm. A similar judgment may be passed upon those Paulician, Albigensian, Paternine and Epicurean dissenters from the Catholic creed who opposed the phalanxes of orthodox with frail imaginative weapons, and alarmed established orders in the state by the audacity of their communistic opinions. Physical science struggled into feeble life in the cells of Gerbert and Roger Bacon. But these men were accounted magicians by the vulgar; and, while the one eventually assumed the tiara, the other was incarcerated in a dungeon. The schools meanwhile resounded still to the interminable dispute upon abstractions. Are only universals real, or has each name a corresponding entity? From the midst of the Franciscans who had persecuted Roger Bacon because he presumed to know more than was consistent with human humility arose John of Parma, adopting and popularizing the mystic prophecy of Joachim of Flora. The reign of the Father is past; the reign of the Son is passing; the reign of the Spirit is at hand. Such was the formula of the Eternal Gospel, which as an unconscious forecast of the Renaissance, has attracted retrospective students by its felicity of adaptation to their historical method. Yet we must remember that this bold intuition of the abbot Joachim indicated a monastic reaction against the tyrannies and corruptions of the Church, rather than a fertile philosophical conception. The Fratelli spiritualists, and similar sects who fed their imagination with his doctrine, expired in the flames to which Fra Dolcino Longino and Margherita were consigned. To what extent the accusations of profligate morals brought against these reforming sectarians were justified remains doubtful; and the same uncertainty rests upon the alleged iniquities of the Templars. It is only certain that at this epoch the fabric of Catholic faith was threatened with various forms of prophetic and Oriental mysticism, symptomatic of a widespread desire to grasp at something simpler, purer and less rigid than Latin theology afforded. Devoid of criticism, devoid of sound learning, devoid of a firm hold on the realities of life, these heresies passed away without solid results and were forgotten.

Naturalism.—We are apt to take for granted that the men of the middle ages were immersed in meditations on the other world, and that their intellectual exercises were confined to abstractions of the schools, hallucinations of the fancy, allegories, visions. This assumption applies indeed in a broad sense to that period which was dominated by intolerant theology, and deprived of positive knowledge. Yet there are abundant signs that the native human instincts, the natural human appetites, remained unaltered and alive beneath the crust of orthodoxy. In the person of a pope like Boniface VIII. those ineradicable forces of the natural man assumed, if we may trust the depositions of ecclesiastics, well acquainted with his life, a form of brutal atheistic cynicism. In the person of an emperor, Frederick II., they emerged under the more agreeable garb of liberal culture and Epicurean scepticism. Frederick dreamed of remodelling society upon a mundane type, which anticipated the large toleration and cosmopolitan enlightenment of the actual Renaissance. But his efforts were defeated by

the unrelenting hostility of the Church, and by the incapacity of his contemporaries to understand his aims. After being forced in his lifetime to submit to authority, he was consigned by Dante to hell. Frederick's ideal of civilization was derived in a large measure from Provence, where a beautiful culture had prematurely bloomed, filling southern Europe with the perfume of poetry and gentle living. Here, if anywhere, it seemed as though the ecclesiastical and feudal fetters of the middle ages might be broken, and humanity might enter on a new stage of joyous and unimpeded evolution. This was, however, not to be. The Church preached Simon de Montfort's crusade, and organized Dominic's Inquisition; what Quinet calls the "Renaissance sociale par l'Amour" was extirpated by sword, fire, famine and pestilence. Meanwhile the Provençal poets had developed their modern language with incomparable richness and dexterity, creating forms of verse and modes of emotional expression which determined the latest mediæval phase of literature in Europe. The naturalism of which we have been speaking found free utterance now in the fabliaux of jongleurs, lyrics of minnesingers, tales of trouvères, romances of Arthur and his knights—compositions varied in type and tone, but in all of which sincere passion and real enjoyment of life pierce through the thin veil of chivalrous mysticism or of allegory with which they were sometimes conventionally draped. The tales of Lancelot and Tristram, the lives of the troubadours and the Wachtlieder of the minnesingers, sufficiently prove with what sensual freedom a knight loved the lady whom custom and art made him profess to worship as a saint. We do not need to be reminded that Beatrice's adorer had a wife and children, or that Laura's poet owned a son and daughter by a concubine, in order to perceive that the mystic passion of chivalry was compatible in the middle ages with commonplace matrimony or vulgar illegitimate connections. But perhaps the most convincing testimony to the presence of this ineradicable naturalism is afforded by the Latin songs of wandering students, known as *Carmina Burana*, written by the self-styled Goliardi. In these compositions, remarkable for their facile handling of mediæval Latin rhymes and rhythms, the allegorizing mysticism which envelops chivalrous poetry is discarded. Love is treated from a frankly carnal point of view. Bacchus and Venus go hand in hand, as in the ancient ante-Christian age. The open-air enjoyments of the wood, the field, the dance upon the village green are sung with juvenile light-heartedness. No grave note, warning us that the pleasures of this earth are fleeting, that the visible world is but a symbol of the invisible, that human life is a probation for the life beyond, interrupts the tinkling music as of castanets and tripping feet which give a novel charm to these unique relics of the 13th century. Goliardic poetry is further curious as showing how the classics even at that early period were a fountain-head of pagan inspiration. In the taverns and low places of amusement haunted by those lettered songsters, on the open road and in the forests trodden by their vagrant feet, the deities of Greece and Rome were not in exile, but at home within the hearts of living men. Thus, while Christendom was still preoccupied with the Crusades, two main forces of the Renaissance, naturalism and enthusiasm for antique modes of feeling, already brought their latent potency to light, prematurely indeed and precociously, yet with a promise that was destined to be kept.

The Mediæval Attitude.—When due regard is paid to these miscellaneous evidences of intellectual and sensual freedom during the middle ages, it will be seen that there were by no means lacking elements of native vigour ready to burst forth. What was wanting was not vitality and licence, not audacity of speculation, not lawless instinct or rebellious impulse. It was rather the right touch on life, the right feeling for human independence, the right way of approaching the materials of philosophy, religion, scholarship and literature that failed. The courage that is born of knowledge, the calm strength begotten by a positive attitude of mind, face to face with the dominant over-shadowing sphinx of theology, were lacking. We may fairly say that natural and untaught people had more of the just intuition that was needed than learned folk trained in the schools. But these people were rendered licentious in revolt or impotent for salutary action by ignorance, by terror, by uneasy dread of the doom declared for heretics and rebels.

human mind. Yet they are not mediæval in the same sense as the song of Roland or the Arthurian cycle. They proved that, though Italy came late into the realm of literature, her action was destined to be decisive and alternative by the introduction of a new spirit, a firmer and more positive grasp on life and art. These qualities she owed to her material prosperity, to her freedom from feudalism, to her secularized church, her commercial nobility, her political independence in a federation of small states. Petrarca and Boccaccio, though they both held the mediæval doctrine that literature should teach some abstruse truth beneath a veil of fiction, differed from Dante in this, that their poetry and prose in the vernacular abandoned both allegory and symbol. In their practice they ignored their theory; Petrarca's lyrics continue the Provençal tradition as it had been reformed in Tuscany, with a subtler and more modern analysis of emotion, a purer and more chastened style than his masters could boast; Boccaccio's tales, in like manner, continue the tradition of the fabliaux, raising that literary species to the rank of finished art, enriching it with humour and strengthening its substance by keen insight into all varieties of character. The *Consolatore* and the *Decameron* distinguish themselves from mediæval literature, not by any return to classical precedents, but by free self-conscious handling of human nature. So much had to be premised in order to make it clear in what relation humanism stood to the Renaissance since the Italian work of Dante, Petrarca and Boccaccio is sufficient to indicate the re-birth of the spirit after ages of apparent deadness. Had the Revival of Learning not intervened, it is probable that the vigorous efforts of these writers alone would have inaugurated a new age of European culture. Yet, while noting this reservation of judgment it must also be remarked that all three felt themselves under some peculiar obligation to the classics. Dante, mediæval as his temper seems to us, chose Virgil for his guide, and ascribed his mastery of style to the study of Virgilian poetry. Petrarca and Boccaccio were, as we have seen, the pioneers of the new learning. They held their writings in the vernacular cheap, and initiated that contempt for the mother tongue which was a note of the earlier Renaissance. Giovanni Villani, the first chronicler who used Italian for the compilation of a methodical history, tells us how he was impelled to write by musing on the ruins of Rome, and thinking of the vanished greatness of the Latin race. We have, therefore, to recognize that the four greatest writers of the 14th century, while the Revival of Learning was yet in its cradle, each after his own fashion acknowledged the vivifying touch upon his spirit of the antique genius. They seem to have been conscious that they could not give the desired impulse to modern literature and art without contact with the classics; and, in spite of the splendour of their achievements in Italian, they found no immediate followers upon that path.

Scholarship and Literature.—The fascination of pure study was so powerful, the Italians at that epoch were so eager to recover the past, that during the 15th century we have before our eyes the spectacle of this great nation deviating from the course of development begun in poetry by Dante and Petrarca, in prose by Boccaccio and Villani, into the channels of scholarship and antiquarian research. The language of the *Consolatore* and *Decameron* was abandoned for revived Latin and discovered Greek. Acquisition supplanted invention; imitation of classical authors suppressed originality of style. The energies of the Italian people were devoted to transcribing the codices, settling texts, translating Greek books into Latin, compiling grammars, commentaries, encyclopaedias, dictionaries, epitomes and ephemerides. During this century the best histories—Bruni's and Poggio's annals of Florence, for example—were composed in Latin after the manner of Livy. The best dissertations, Landino's *Camaldunenses*, Valla's *De Voluptate*, were laboured imitations of Cicero's *Tusculans*. The best verse, Pontano's elegies, Politian's hexameters, were, in like manner Latin; public orations upon ceremonial occasions were delivered in the Latin tongue; correspondence, official and familiar, was carried on in the same language; even the fabliaux received, in Poggio's *Facitiae*, a dress of elegant Latinity. The noticeable barrenness of Italian literature at this period is referable to the fact that men of genius and talent devoted themselves to

erudition and struggled to express their thoughts and feelings in a speech which was not natural. Yet they were engaged in a work of incalculable importance. At the close of the century the knowledge of Greece and Rome had been reappropriated and placed beyond the possibility of destruction; the chasm between the old and new world had been bridged; mediæval modes of thinking and discussing had been superseded; the staple of education, the common culture which has brought all Europe into intellectual agreement, was already in existence. Humanism was now an actuality. Owing to the uncritical veneration for antiquity which then prevailed, it had received a strong tincture of pedantry. Its professors, in their revolt against the middle ages, made light of Christianity and paraded paganism. What was even worse from an artistic point of view, they had contracted puerilities of style, vanities of rhetoric, stupidities of wearisome citation. Still, at the opening of the 16th century, it became manifest what fruits of noble quality the Revival of Letters was about to bring forth for modern literature. Two great scholars, Lorenzo de' Medici and Politian, had already returned to the practice of Italian poetry. Their work is the first absolutely modern work—modern in the sense of having absorbed the stores of classic learning and reproduced those treasures in forms of simple, natural, native beauty. Bolardo occupies a similar position by the fusion of classic mythology with chivalrous romance in his *Orlando Innamorato*. But the victor's laurels were reserved for Ariosto whose *Orlando Furioso* is the purest and most perfect extant example of Renaissance poetry. It was not merely in what they had acquired and assimilated from the classics that these poets showed the transformation effected in the fields of literature by humanism. The whole method and spirit of the mediæval art had been abandoned. That of the *cinque cento* is positive, defined, mundane. The deity, if deity there be, that rules in it, is beauty. Interest is confined to the actions, passions, sufferings and joys of human life, to its pathetic, tragic, humorous and sentimental incidents. Of the state of souls beyond the grave we hear and are supposed to care nothing. In the drama the pedantry of the Revival which had not injured romantic literature made itself perniciously felt. Rules were collected from Horace and Aristotle. Seneca was chosen as the model of tragedy; Plautus and Terence supplied the groundwork of comedy. Thus in the plays of Rucellai, Trissino, Spertone and other tragic poets, the nobler elements of humanism, considered as a revelation of the world and man, obtained no free development. Even the comedies of the best authors are too observant of Latin precedents, although some pieces of Machiavelli, Ariosto, Aretino, Cecchi and Gelli are admirable for vivid delineation of contemporary manners.

Fine Arts.—The relation of the plastic arts to the Revival of Learning is similar to that which has been sketched in the case of poetry. Cimabue started with work which owed nothing directly to antiquity. At about the same time Nicola Pisano (d. 1278) studied the style of sculpture in fragments of Graeco-Roman marbles. His manner influenced Giotto, who set painting on a forward path. Fortunately for the unimpeded expansion of Italian art, little was brought to light of antique workmanship during the 14th and 15th centuries. The classical stimulus came to painters, sculptors and architects chiefly through literature. Therefore there was narrow scope for imitation; and the right spirit of humanism displayed itself in a passionate study of perspective, nature and the nude. Yet we find in the writings of Ghiberti and Alberti, we notice in the masterpieces of these men and their contemporaries Brunelleschi and Donatello, how even in the 15th century the minds of artists were fascinated by what survived of classic grace and science. Gradually, as the race became penetrated by antique thought, the earlier Christian motives of the arts yielded to pagan subjects. Gothic architecture, which had always flourished feebly on Italian soil, was supplanted by a hybrid Roman style. The study of Vitruvius gave strong support to that pseudo-classic manner which, when it had reached its final point in Palladio's work, overspread the whole of Europe and dominated taste during two centuries. But the perfect plastic art of Italy, the pure art of the *cinque cento*, the painting of Raphael, Da Vinci, Titian and Correggio, the sculpture of Donatello, Michel-

angelo and Sansovino, the architecture of Bramante, Omodeo, and the Venetian Lombardi, however much imbued with the spirit of the classical revival, take rank beside the poetry of Ariosto as a free intelligent product of the Renaissance. That is to say, it is not so much an outcome of studies in antiquity as an exhibition of emancipated modern genius freed and illuminated by the masterpieces of the past. It indicates a separation from the middle ages, inasmuch as it is permanently natural. Its religion is joyous, sensuous, dramatic, terrible, but in each and all of its many-sided manifestations strictly human. Its touch on classical mythology is original, rarely imitative or pedantic. The art of the Renaissance was an apocalypse of the beauty of the world and man in unaffected spontaneity, without side thoughts for piety or erudition, inspired by pure delight in loveliness and harmony for their own sakes.

Science and Philosophy.—In the fields of science and philosophy humanism wrought similar important changes. Petrarch began by waging relentless war against the logicians and materialists of his own day. With the advance made in Greek studies scholastic methods of thinking fell into contemptuous oblivion. The newly aroused curiosity for nature encouraged men like Alberti, Da Vinci, Toscanelli and Da Porta to make practical experiments, penetrate the working of physical forces, and invent scientific instruments. Anatomy began to be studied, and the time was not far distant when Titian should lend his pencil to the epoch-making treatise of Vesalius. The middle ages had been satisfied with absurd and visionary notions about the world around them, while the body of man was regarded with too much suspicion to be studied. Now the right method of interrogating nature with patience and loving admiration was instituted. At the same time the texts of ancient authors supplied hints which led to discoveries so far-reaching in their results as those of Copernicus, Columbus and Galileo. In philosophy, properly so called, the humanistic scorn for mediæval dullness and obscurity swept away theological metaphysics as valueless. But at first little beyond empty rhetoric and clumsy compilation was substituted. The ethical treatises of the scholars are deficient in substance, while Ficino's attempt to revive Platonism betrays an uncritical conception of his master's drift. It was something, however, to have shaken off the shackles of ecclesiastical authority; and, even if a new authority, that of the ancients, was accepted in its stead, still progress was being made toward sounder methods of analysis. This is noticeable in Pomponazzo's system of materialism, based on the interpretation of Aristotle, but revealing a virile spirit of disinterested and unprejudiced research. The thinkers of southern Italy, Telesio, Bruno and Campanella, at last opened the two chief lines on which modern speculation has since moved. Telesio and Campanella may be termed the predecessors of Bacon. Bruno was the precursor of the idealistic schools. All three alike strove to disengage their minds from classical as well as ecclesiastical authority, proving that the emancipation of the will had been accomplished. It must be added that their writings, like every other product of the Renaissance, except its purest poetry and art, exhibit a hybrid between mediæval and modern tendencies. Childish ineptitudes are mingled with intuitions of maturest wisdom and seeds of future thought germinate in the decaying refuse of past systems.

Criticism.—Humanism in its earliest stages was uncritical. It absorbed the relics of antiquity with omnivorous appetite and with very imperfect sense of the distinction between worse and better work. Yet it led in process of time to criticism. The critique of literature began in the lecture-room of Politian, in the printing house of Aldus, and in the school of Vittorino. The critique of Roman law started under Politian's auspices, upon a more liberal course than that which had been followed by the powerful but narrow-sighted glossators of Bologna. Finally, in the court of Naples arose that most formidable of all critical engines, the critique of established ecclesiastical traditions and spurious historical documents. Valla by one vigorous effort destroyed the False Decretals and exposed the Donation of Constantine to ridicule, paving the way for the polemic carried on against the dubious pretensions of the papal throne by scholars of the

Reformation. A similar criticism, conducted less on lines of erudition than of persiflage and irony, ransacked the moral abuses of the Church and played around the foundations of Christianity. This was tolerated by men who repeated the witty epigram, attributed to Leo X, "What profit has not that fable of Christ brought us!" The same critical and philosophic spirit working on the materials of history produced a new science, the honours of which belong to Machiavelli. He showed, on the one side, how the history of a people can be written with a recognition of fixed principles, and at the same time with an artistic feeling for personal and dramatic episodes. On the other side, he addressed himself to the analysis of man considered as a political being, to the anatomy of constitutions and the classification of governments, to the study of motives underlying public action, the secrets of success and the causes of failure in the conduct of affairs. The unscrupulous rigour with which he applied his scientific method, and the sinister deductions he thought himself justified in drawing from the results it yielded, excited terror and repulsion. Nevertheless a department had been added to the intellectual empire of mankind, in which fellow-workers, like Guicciardini at Florence, and subsequently Sarpi at Venice, were not slow to follow the path traced by Machiavelli.

Education.—The object of the foregoing paragraphs has been to show in what way the positive, inquisitive, secular, exploratory spirit of the Renaissance, when toned and controlled by humanism penetrated the regions of literature, art, philosophy and science. It becomes at this point of much moment to consider how social manners in Italy were modified by the same causes, since the type developed there was in large measure communicated together with the new culture to the rest of Europe. The first subject to be noticed under this heading is education. What has come to be called a classical education was the immediate product of the Italian Renaissance. The Universities of Bologna, Padua, and Salerno had been famous through the later middle ages for the study of law, physics and medicine; and during the 15th and 16th centuries the first two still enjoyed celebrity in these faculties. But at this period no lecture-rooms were so crowded as those in which professors of antique literature and language read passages from the poets and orators, taught Greek, and commented upon the systems of philosophers. The mediæval curriculum offered no defined place for the new learning of the Revival, which had indeed no recognised name. Chairs had therefore to be founded under the title of rhetoric, from which men like Chrysoloras and Guarino, Filelfo and Politian expounded orally to hundreds of eager students from every town of Italy and every nation of Europe their accumulated knowledge of antiquity. One mass of Greek and Roman erudition, including history and metaphysics, law and science, civic institutions and the art of war, mythology and magistracies, metrical systems and oratory, agriculture and astronomy, domestic manners and religious rites, grammar and philology, biology and numismatics, formed the miscellaneous subject-matter of this so-styled rhetoric. Notes taken at these lectures supplied young scholars with hints for further exploration; and a certain tradition of treating antique authors for the display of general learning, as well as for the elucidation of their texts, came into vogue, which has determined the method of scholarship for the last three centuries in Europe. The lack of printed books in the first period of the Revival, and the comparative rarity of Greek erudition among students, combined with the intense enthusiasm aroused for the new gospel of the classics, gave special value to the personal teaching of these professors. They journeyed from city to city, attracted by promises of higher pay, and allured by ever-growing laurels of popular fame. Each large town established its public study, academy or university—similar institutions under varying designations—for the exposition of the *literæ humaniores*. The humanists, or professors of that branch of knowledge, became a class of the highest dignity. They were found in the chanceries of the republics, in the papal curia, in the council chambers of princes, at the headquarters of condottieri, wherever business had to be transacted, speeches to be made and the work of secretaries to be performed. Furthermore, they undertook the charge of private education, opening schools

which displaced the mediaeval system of instruction and taking engagements as tutors in the families of despots, noblemen and wealthy merchants. The academy established by Vittorino da Feltré at Mantua under the protection of Gian Francesco Gonzaga, for the training of pupils of both sexes, might be chosen as the type of this Italian method. His scholars who were lodged in appropriate buildings met daily to hear the master read and comment on the classics. They learned portions of the best authors by heart, exercised themselves in translating from one language to another and practised composition in prose and verse. It was Vittorino's care to see that while their memories were duly stored with words and facts their judgment should be formed by a critical analysis, attention to style and comparison of the authors of a decadent age with those who were acknowledged classics. During the hours of recreation suitable physical exercises, as fencing, riding, and gymnastics, were conducted under qualified trainers. From this sketch it will be seen how closely the educational system which came into England during the reign of the Tudors, and which has prevailed until the present time, was modelled upon the Italian type. English youths who spend their time at Eton between athletic sports and Latin verse, and who take a first class in *Litterae Humaniores* at Oxford are pursuing the same course of physical and mental discipline as the princes of Gonzaga or Montefeltro in the 15th century.

The humanists effected a deeply penetrating change in social manners. Through their influence as tutors, professors, orators and courtiers, society was permeated by a fresh ideal of culture. To be a gentleman in Italy meant at this epoch to be a man acquainted with the rudiments at least of scholarship, refined in diction, capable of corresponding or of speaking in choice phrases, open to the beauty of the arts, intelligently interested in archaeology, taking for his models of conduct the great men of antiquity, rather than the saints of the Church. He was also expected to prove himself an adept in physical exercises and in the courteous observances which survived from chivalry. The type is set before us by Castiglione in that book upon the courtier which went the round of Europe in the 16th century. It is further emphasized in a famous passage of the *Orlando Innamorato* where Bolardo compares the Italian ideal of an accomplished gentleman with the coarser type admired by nations of the north. To this point the awakened intelligence of the Renaissance, instructed by humanism, polished by the fine arts, expanding in genial conditions of diffused wealth, had brought the Italians at a period when the rest of Europe was comparatively barbarous.

Defects of the Renaissance.—This picture has undoubtedly a darker side. Humanism in its revolt against the middle ages was, as we have seen already, mundane, pagan, irreligious, positive! The Renaissance can, after all, be regarded only as a period of transition in which much of the good of the past was sacrificed while some of the evil was retained, and neither the bad nor the good of the future was brought clearly into fact. Beneath the surface of brilliant social culture lurked gross appetites and savage passions, unrestrained by mediaeval piety, untutored by modern experience. Italian society exhibited an almost unexampled spectacle of literary, artistic and courtly refinement crossed by brutalities of lust, treasons, poisonings, assassinations, violence. A succession of worldly pontiffs brought the Church into flagrant discord with the principles of Christianity. Steeped in pagan learning, desirous of imitating the manners of the ancients, thinking and feeling in harmony with Ovid and Theocritus, and at the same time rendered cynical by the corruption of papal Rome, the educated classes lost their grasp upon morality. Political honesty ceased almost to have a name in Italy. The Christian virtues were scorned by the foremost actors and the ablest thinkers of the time, while the antique virtues were themes for rhetoric rather than moving springs of conduct. This is apparent to all students of Machiavelli and Guicciardini, the profoundest analysts of their age, the bitterest satirists of its vices, but themselves infected with its incapacity for moral goodness. The Italians were not only vitiated; they had also become impotent for action and re-

But there was also a great school of Christian humanists intent upon reconciling the gospel with the Greek philosophers.

At the height of the Renaissance the five great Powers in the peninsula formed a confederation of independent but mutually attractive and repellent states. Equilibrium was maintained by diplomacy, in which the humanists played a foremost part, casting a network of intrigue over the nation which helped in no small measure to stimulate intelligence and create a common medium of culture, but which accustomed statesmen to believe that everything could be achieved by wire-pulling. Wars were conducted on a showy system by means of mercenaries, who played a safe game in the field and developed a system of bloodless campaigns. Meanwhile the people grew up unused to arms. When Italy between the years 1494 and 1530 became the battlefield of French, German and Spanish forces, it was seen to what a point of helplessness the political, moral and social conditions of the Renaissance had brought the nation.

Spread of the New Learning.—It was needful to study at some length the main phenomena of the Renaissance in Italy, because the history of that phase of evolution in the other Western races turns almost entirely upon points in which they either adhered to or diverged from the type established there. Speaking broadly, what France, Germany, Spain and England assimilated from Italy at this epoch was in the first place the new learning as it was then called. This implied the new conception of human life, the new interest in the material universe, the new method of education, and the new manners, which we have seen to be inseparable from Italian humanism. Under these forms of intellectual enlightenment and polite culture the renaissance of the human spirit had appeared in Italy, where it was more than elsewhere connected with the study of classical antiquity. But that audacious exploratory energy which formed the motive force of the Renaissance as distinguished from the Revival of Learning took, as we shall see, very different directions in the several nations who now were sending the flower of their youth to study at the feet of Italian rhetoricians.

The Renaissance ran its course in Italy with strange indifference to consequences. The five great Powers, held in equilibrium by Lorenzo de' Medici, dreamed that the peninsula could be maintained in *status quo* by diplomacy. The Church saw no danger in encouraging a pseudo-pagan ideal of life, violating its own principle of existence by assuming the policy of an aggrandizing secular state, and outraging Christendom openly by its acts and utterances. Society at large was hardly aware that an intellectual force of stupendous magnitude and incalculable explosive power had been created by the new learning. Why should not established institutions proceed upon the customary and convenient methods of routine, while the delights of existence were augmented, manners polished, arts developed and a golden age of epicurean ease made decent by a state religion which no one cared to break with because no one was left to regard it seriously? This was the attitude of the Italians when the Renaissance, which they had initiated as a thing of beauty, began to operate as a thing of power beyond the Alps.

GERMANY

Germany was already provided with universities, seven of which had been founded between 1348 and 1409. In these haunts of learning the new studies took root after the year 1440, chiefly through the influence of travelling professors, Peter Luder and Samuel Karoch. German scholars made their way to Lombard and Tuscan lecture-rooms, bringing back the methods of the humanists. Greek, Latin and Hebrew erudition soon found itself at home on Teutonic soil. Like Italian men of letters, these pioneers of humanism gave a classic turn to their patronymics: unfamiliar names, Crotus Rubenacus and Pierius Graecus, Capiton and Lupambulus Ganymedes, Oecolampadius and Melanchthon, resounded on the Rhine. A few of the German princes, among whom Maximilian, the prince cardinal Albert of Mainz, Frederick the Wise of Saxony, and Eberhard of Württemberg deserve mention, exercised a not insignificant influence on letters by the foundation of new universities and the patronage of learned men. The cities of Strasbourg, Nuremberg, Augsburg, Basle, became centres of learned coteries which gathered round scholars like Wimpfel-

ing, Brant, Peutinger, Schedel, and Pirckheimer, artists like Dürer and Holbein, painters of the eminence of Froben. Academies in imitation of Italian institutions came into existence, the two most conspicuous named after the Rhine and the Danube, holding their headquarters respectively at Heidelberg and Vienna. Crowned poets, of whom the most eminent was Conrad Celtes Protucius (Pickel!) emulated the fame of Politian and Pothano. Yet though the Renaissance was thus widely communicated to the centres of German intelligence, it displayed a different character from that which it assumed in Italy. Gothic art, which was indigenous in Germany, yielded but little to southern influences. Such work as that of Dürer, Vischer, Cranach, Schöngauer, Holbein, consummate as it was in technical excellence, did not assume Italian forms of loveliness, did not display the paganism of the Latin races. The modification of Gothic architecture by pseudo-Roman elements of style was incomplete. What Germany afterwards took of the Palladian manner was destined to reach it on a circuitous route from France. In like manner the new learning failed to penetrate all classes of society with the rapidity of its expansion in Italy, nor was the new ideal of life and customs so easily substituted for the mediaeval. The German aristocracy, as Aeneas Sylvius had noticed, remained for the most part barbarous, addicted to gross pleasures, contemptuous of culture. The German dialects were too rough to receive that artistic elaboration under antique influences which had been so facile in Tuscany. The doctors of the universities were too wedded to their antiquated manuals and methods, too satisfied with dullness, too proud of titles and diplomas, too anxious to preserve ecclesiastical discipline and to repress mental activity, for a genial spirit of humanism to spread freely. Not in Cologne or Tübingen but in Padua and Florence did the German pioneers of the Renaissance acquire their sense of liberal studies. And when they returned home they found themselves encumbered with stupidities, jealousies and rancours. Moreover the temper of these more enlightened men was itself opposed to Italian indifference and immorality; it was pugnacious and polemical, eager to beat down the arrogance of monks and theologians rather than to pursue an ideal of aesthetic self-culture. To a student of the origins of German humanism it is clear that something very different from the Renaissance of Lorenzo de' Medici and Leo X. was in preparation from the first upon Teutonic soil. Far less plastic and form-loving than the Italian, the German intelligence was more penetrative, earnest, disputative, occupied with substantial problems. Starting with theological criticism, proceeding to the stage of solid studies in the three learned languages, German humanism occupied the attention of a widely scattered sect of erudite scholars; but it did not arouse the interest of the whole nation until it was forced into a violently militant attitude by Pfefferkorn's attack on Reuchlin. That attempt to extinguish honest thought prepared the Reformation; and humanism after 1518 was absorbed in politico-religious warfare.

Humanism and the German Reformation.—The point of contact between humanism and the Reformation in Germany has to be insisted on; for it is just here that the relation of the Reformation to the Renaissance in general makes itself apparent. As the Renaissance had its precursory movements in the mediaeval period, so the German Reformation was preceded by Wycliffe and Huss, by the discontents of the Great Schism, and by the councils of Constance and Basel. These two main streams of modern progress had been proceeding upon different tracks to diverse issues, but they touched in the studies stimulated by the Revival, and they had a common origin in the struggle of the spirit after self-emancipation. Johann Reuchlin, who entered the lecture-room of Argyropoulos at Rome in 1482, Erasmus of Rotterdam, who once dwelt at Venice as the house guest of the Aldi, applied their critical knowledge of Hebrew and Greek to the elucidation and diffusion of the Bible. To the Germans, as to all nations of that epoch, the Bible came as a new book, because they now read it for the first time with eyes opened by humanism. The touch of the new spirit which had evolved literature, art and culture in Italy sufficed in Germany to recreate Christianity. This new spirit in Italy emancipated human intelligence by the classics; in Ger-

many it emancipated the human conscience by the Bible. The indignation excited by Leo X.'s sale of indulgences, the moral rage stirred in Northern hearts by papal abominations in Rome were external causes which precipitated the schism between Teutonic and Latin Christianity. The Reformation, inspired by the same energy of resuscitated life as the Renaissance, assisted by the same engines of the printing-press and paper, using the same apparatus of scholarship, criticism, literary skill, being in truth another manifestation of the same world-movement under a diverse form, now posed itself as an irreconcilable antagonist to Renaissance Italy. It would be difficult to draw any comparison between German and Italian humanists to the disparagement of the former. Reuchlin was no less learned than Ficco; Melancthon no less humane than Ficino; Erasmus no less witty and far more trenchant than Petrarch; Ulrich von Hutten no less humorous than Folengo; Paracelsus no less fantastically learned than Cardano. But the cause in which German intellect and will were enlisted was so different that it is difficult not to make a formal separation between that movement which evolved culture in Italy and that which restored religion in Germany, establishing the freedom of intelligence in the one sphere and the freedom of conscience in the other. The truth is that the Reformation was the Teutonic Renaissance. It was the emancipation of the reason on a line neglected by the Italians, more important indeed in its political consequences, more weighty in its bearing on rationalistic developments than the Italian Renaissance, but none the less an outcome of the same ground-influences. We have already in this century reached a point at which, in spite of stubborn Protestant dogmatism and bitter Catholic reaction, we can perceive how the ultimate enfranchisement of man will be the work of both.

The Counter-Reformation.—The German Reformation was incapable of propagating itself in Italy, chiefly for the reason that the intellectual forces which it represented and employed had already found specific outlet in that country. It was not in the nature of the Italians, sceptical and paganism by the revival, to be keenly interested about questions which seemed to revive the scholastic disputes of the middle ages. It was not in their external conditions, suffering as they were from invasions, enthralled by despots, to use the Reformation as a lever for political revolution. Yet when a tumultuary army of so-called Lutherans sacked Rome in 1527, no sober thinker doubted that a new agent had appeared in Europe which would alter the destinies of the peninsula. The Renaissance was virtually closed so far as it concerned Italy, when Clement VII. and Charles V. struck their compact at Bologna in 1530. This compact proclaimed the principle of monarchical absolutism, supported by papal authority, itself monarchially absolute, which influenced Europe until the outbreak of the Revolution. A reaction immediately set in both against the Renaissance and the Reformation. The Council of Trent, opened in 1545 and closed in 1563, decreed a formal purgation of the Church, affirmed the fundamental doctrines of Catholicism, strengthened the papal supremacy, and inaugurated that movement of resistance which is known as the Counter-Reformation. The complex onward effort of the modern nations, expressing itself in Italy as Renaissance, in Germany as Reformation, had aroused the forces of conservatism. The four main instruments of the reaction were the papacy, which had done so much by its sympathy with the revival to promote the humanistic spirit it now dreaded, the strength of Spain, and two Spanish institutions planted on Roman soil—the Inquisition and the Society of Jesus. The principle contended for and established by this reaction was absolutism as opposed to freedom—monarchical absolutism, papal absolutism, the suppression of energies liberated by the Renaissance and the Reformation. The partial triumph of this principle was secure, in as much as the majority of established powers in Church and State felt threatened by the revolutionary opinions afloat in Europe. Renaissance and Reformation were, moreover, already at strife. Both, too, were spiritual and elastic tendencies toward progress, ideals rather than solid organisms.

SPAIN

The part played by Spain in this period of history was deter-

mined in large measure by external circumstance. The Spaniards became one nation by the conquest of Granada and the union of the crowns of Castile and Aragon. The war of national aggrandizement being in its nature a crusade, inflamed the religious enthusiasm of the people. It was followed by the expulsion of Jews and Moors, and by the establishment of the Inquisition on a solid basis, with powers formidable to the freedom of all Spaniards from the peasant to the throne. These facts explain the decisive action of the Spanish nation on the side of Catholic conservatism, and help us to understand why their brilliant achievements in the field of culture during the 16th century were speedily followed by stagnation. It will be well, in dealing with the Renaissance in Spain, to touch first upon the arts and literature, and then to consider those qualities of character in action whereby the nation most distinguished itself from the rest of Europe. Architecture in Spain, emerging from the Gothic stage, developed an Early Renaissance style of bewildering richness by adopting elements of Arabic and Moorish decoration. Sculpture exhibited realistic vigour of indubitably native stamp; and the minor plastic crafts were cultivated with success on lines of striking originality. Painting grew from a homely stock, until the work of Velasquez showed that Spanish masters in this branch were fully abreast of their Italian contemporaries. To dwell here upon the Italianizing versifiers, moralists and pastoral romancers who attempted to refine the vernacular of the *Romancero* would be superfluous. They are mainly noticeable as proving that certain circles in Spain were willing to accept the Italian Renaissance. But the real force of the people was not in this courtly literary style. It expressed itself at last in the monumental work of *Don Quixote*, which places Cervantes beside Rabelais, Ariosto and Shakespeare as one of the four supreme exponents of the Renaissance. The affectations of decadent chivalry disappeared before its humour; the lineaments of a noble nation, animated by the youth of modern Europe emerging from the middle ages, were portrayed in its enduring pictures of human experience. The Spanish drama, meanwhile untrammelled by those false canons of pseudo-classic taste which fettered the theatre in Italy and afterwards in France, rose to an eminence in the hands of Lope de Vega and Calderon which only the English, and the English only in the masterpieces of three or four playwrights, can rival. Camoens in the *Lusiad*, if we may here group Portugal with Spain, was the first modern poet to compose an epic on a purely modern theme, vying with Virgil, but not bending to pedantic rules, and breathing the spirit of the age of heroic adventures and almost fabulous discoveries into his melodious numbers. What has chiefly to be noted regarding the achievements of the Spanish race in arts and letters at this epoch is their potent national originality. The revival of learning produced in Spain no slavish imitation as it did in Italy, no formal humanism, and, it may be added, very little of fruitful scholarship. The Renaissance here, as in England, displayed essential qualities of intellectual freedom, delight in life, exultation over rediscovered earth and man. The note of Renaissance work in Germany was still Gothic. This we feel in the penetrative earnestness of Dürer, in the homeliness of Hans Sachs, in the grotesque humour of *Eulenspiegel*, and the *Narrenschiff*, the sombre pregnancy of the Faust legend, the almost stolid mastery of Holbein. It lay not in the German genius to escape from the preoccupations and the limitations of the middle ages, for this reason mainly that what we call mediæval was to a very large extent Teutonic. But on the Spanish peninsula, in the masterpieces of Velasquez, Cervantes, Camoens, Calderon, we emerge into an atmosphere of art definitely national, distinctly modern, where solid natural forms stand before us realistically modelled, with light and shadow on their rounded outlines, and where the airiest creatures of the fancy take shape and weave a dance of rhythmic, light, incomparable intricacy. The Spanish Renaissance would in itself suffice, if other witnesses were wanting, to prove how inaccurate is the theory that limits this movement to the revival of learning. Touched by Italian influences, enriched and fortified by the new learning, Spanish genius walked firmly forward on its own path. It was crushed only by forces generated in the nation that produced it, by the Inquisition and by despotic Catholic

absolutism.

In the history of the Renaissance, Spain and Portugal represent the exploration of the ocean and the colonization of the other hemisphere. The voyages of Columbus and Vespucci to America, the rounding of the Cape by Diaz and the discovery of the sea route to India by Vasco da Gama, Cortés's conquest of Mexico and Pizarro's conquest of Peru, marked a new era for the human race and inaugurated the modern age more decisively than any other series of events has done. It has recently been maintained that modern European history is chiefly an affair of competition between confederated states for the possession of lands revealed by Columbus and Da Gama. Without challenging or adopting this speculation, it may be safely affirmed that nothing so pregnant of results has happened as this exploration of the globe. To say that it displaced the centre of gravity in politics and commerce, substituting the ocean for the Mediterranean, detroning Italy from her seat of central importance in traffic, depressing the eastern and elevating the western Powers of Europe, opening a path for Anglo-Saxon expansiveness, forcing philosophers and statesmen to regard the Occidental nations as a single group in counterpoise to other groups of nations, the European community as one unit correlated to other units of humanity upon this planet, is truth enough to vindicate the vast significance of these discoveries. The Renaissance, far from being the re-birth of antiquity with its civilization confined to the Mediterranean and the Hercules' Pillars beyond which lay Cimmerian darkness, was thus effectively the entrance upon a quite incalculably wider stage of life on which mankind at large has since enacted one great drama. While Spanish navies were exploring the ocean, and Spanish paladins were overturning empires, Charles V headed the reaction of Catholicism against reform. Stronger as king of Spain than as emperor, for the Empire was little but a name, he lent the weight of his authority to that system of coercion and repression which enslaved Italy, desolated Germany with war, and drowned the Low Countries in blood. Philip II, with full approval of the Spanish nation, pursued the same policy in an even stricter spirit. He was powerfully assisted by two institutions in which the national character of Spain expressed itself, the Inquisition and the Society of Jesus. Of the former it is not needful to speak here. But we have to observe that the last great phenomenon of the Spanish Renaissance was Ignatius Loyola, who organized the militia by means of which the Church worked its Counter-Reformation. His motto, *Perinde ac cadaver*, expressed that recognition of absolutism which papacy and monarchy demanded for their consolidation. (See JESUS, SOCIETY OF and LOYOLA, ST. IGNATIUS OF.)

FRANCE

The logical order of an essay which attempts to show how Renaissance was correlated to Reformation and Counter-Reformation has necessitated the treatment of Italy, Germany and Spain in succession; for these three nations were the three main agents in the triple process to be analysed. It was due to their specific qualities, and to the diverse circumstances of their external development that the re-birth of Europe took this form of duplex action on the lines of intellectual and moral progress, followed by reaction against mental freedom. We have now to speak of France, which earliest absorbed the influence of the Italian revival, and of England which received it latest. The Renaissance may be said to have begun in France with Charles VIII.'s expedition to Naples, and to have continued until the extinction of the house of Valois. Louis XII. and Francis I. spent a considerable portion of their reigns in the attempt to secure possession of the Italian provinces they claimed. Henry II.'s queen was Catherine of the Medicean family; and her children, Charles IX. and Henry III., were Italianated Frenchmen. Thus the connection between France and Italy during the period 1494-1589 was continuous. The French passed to and fro across the Alps on military and peaceful expeditions. Italians came to France as courtiers, ambassadors, men of business, captains and artists. French society assumed a strong Italian colouring, nor were the manners of the court very different from those of an Italian city, except that

taste. Some of the names just mentioned remind us that in France, as in Germany and Holland, the Reformation was closely connected with the revival of learning. Humanism has never been in the narrow sense of that term Protestant; still less has it been strictly Catholic. In Italy it fostered a temper of mind decidedly averse to theological speculation and religious earnestness. In Holland and Germany with Erasmus, Reuchlin and Melancthon it developed types of character, urbane, reflective, pointedly or gently critical, which left to themselves would not have plunged the north of Europe into the whirlpool of belligerent reform. Yet none the less was the new learning, through the open spirit of inquiry it nourished, its vindication of the private reason, its enthusiasm for republican antiquity, and its proud assertion of the rights of human independence, linked by a strong and subtle chain to that turbid revolt of the individual consciousness against spiritual despotism draped in fallacies and throned upon abuses. To this rebellion we give the name of Reformation. But while the necessities of antagonism to papal Rome made it assume at first the form of narrow and sectarian opposition, it marked in fact a vital struggle of the intellect towards truth and freedom, involving future results of scepticism and rationalistic audacity from which its earlier champions would have shrunk. It marked, moreover, in the condition of armed resistance against established authority which was forced upon it by the Counter-Reformation, a firm resolve to assert political liberty, leading in the course of time to a revolution with which the rebellious spirit of the Revival was sympathetic. This being the relation of humanism in general to reform, French learning in particular displayed such innovating boldness as threw many of its most conspicuous professors into the camp at war with Rome. Calvin, a French student of Picard origin, created the type of Protestantism to which the majority of French Huguenots adhered. This too was a moment at which philosophical seclusion was hardly possible. In a nation so tumultuously agitated one side or the other had to be adopted. Those of the French humanists who did not proclaim Huguenot opinions found themselves obliged with Muret to lend their talents to the Counter-Reformation, or to suffer persecution for heterodoxy like Dole. The Church, terrified and infuriated by the progress of reform, suspected learning on its own account. To be an eminent scholar was to be accused of immorality, heresy and atheism in a single indictment; and the defence of weaker minds lay in joining the Jesuits as Heinisus was fain to do. France had already absorbed the earlier Renaissance in an Italianizing spirit before the Reformation made itself felt as a political actuality. This fact, together with the strong Italian bias of the Valois, serves to explain in some degree the reason why the Counter-Reformation entailed those fierce entangled civil wars, massacres of St. Bartholomew, murders of the Guises, regicides, treasons and empoisonments, that terminated with the compromise of Henry IV. It is no part of the present subject to analyse the political, religious and social interests of that struggle. The upshot was the triumph of the Counter-Reformation, and the establishment of its principle, absolutism, as the basis of French government. It was a French king who, when the nation had been reduced to order, uttered the famous word of absolutism, "*L'Etat, c'est moi*."

THE NETHERLANDS

The Renaissance in the Low Countries, as elsewhere, had its brilliant age of arts and letters. During the middle ages the wealthy free towns of Flanders flourished under conditions not dissimilar to those of the Italian republics. They raised miracles of architectural beauty, which were modified in the 15th and 16th centuries by characteristic elements of the new style. The Van Eycks, followed by Memling, Metsys, Mabuse, Lucas van Leyden, struck out a new path in the revival of painting and taught Europe the secret of oil-colouring. But it was reserved for the 17th century to witness the flower and fruit time of this powerful art in the work of Porbus, Rubens and Vandyck, in the Dutch schools of landscape and home-life, and in the unique masterpieces of Rembrandt. We have a right to connect this later period with the Renaissance, because the distracted state of the Netherlands during the 16th century suspended, while it could not extinguish,

their aesthetic development. The various schools of the 17th century, moreover, are animated with the Renaissance spirit no less surely than the Florentine school of the 15th or the Venetian of the 16th. The animal vigour and carnal enjoyment of Rubens, the refined Italianizing beauty of Vandyck, the mystery of light and gloom on Rembrandt's panels, the love of nature in Ruysdael, Cuyp and Van Hooghe, with their luminously misty skies, silvery daylight and broad expanse of landscape, the interest in common life displayed by Ter Borch, Van Steen, Douw, Ostade and Teniers, the instinct for the beauty of animals in Potter, the vast sea spaces of Vanderveldt, the grasp on reality, the acute intuition into character in portraits, the scientific study of the world and man, the robust sympathy with natural appetites, which distinguish the whole art of the Low Countries, are a direct emanation from the Renaissance.

The vernacular in the Netherlands profited at first but little by the impulse which raised Italian, Spanish, French and English to the rank of classic languages. But humanism, first of all in its protagonist Erasmus, afterwards in the long list of critical scholars and editors, Lpsius, Heinisus and Grotius, in the printers, Elzevir and Plantin, developed itself from the centre of the Leyden university with massive energy, and proved that it was still a motive force of intellectual progress. In the fields of classical learning the students of the Low Countries broke new ground chiefly by methodical collection, classification and comprehensive criticism of previously accumulated stores. Their works were solid and substantial edifices, forming the substratum for future scholarship. In addition to this they brought a philosophy and scientific thoroughness to bear on studies which had been pursued in a more literary spirit. It would, however, be uncritical to pursue this subject further; for the encyclopaedic labours of the Dutch philologists belong to a period when the Renaissance was overpast. For the same reason it is inadmissible to do more than mention the name of Spinoza here.

The Netherlands became the battlefield of Reformation and Counter-Reformation in even a stricter sense than France. Here the antagonistic principles were plainly posed in the course of struggle against foreign despotism. The conflict ended in the assertion of political independence, as opposed to absolute dominion. Europe in large measure owes the modern ideal of political liberty to that spirit of stubborn resistance which broke the power of Spain. Recent history, and, in particular, the history of democracy, claims for its province the several stages whereby this principle was developed in England and America, and its outburst in the frenzy of the French Revolution. It is enough here to have alluded to the part played by the Low Countries in the genesis of a motive force which may be described as the last manifestation of the Renaissance striving after self-emancipation.

ENGLAND

The insular position of England combined with the nature of the English has allowed the country to feel the vibration of European movements later and with less of shock than the continental nations. Before a wave of progress has reached its shores there has been the opportunity of watching it as spectators, and of considering how to receive it. Revolutions have passed from the tumultuous stages of their origin into some settled and recognizable state before we have been called upon to cope with them. It was thus that England took the influences of the Renaissance and Reformation simultaneously, and almost at the same time found herself engaged in that struggle with the Counter-Reformation which, crowned by the defeat of the Spanish Armada, stimulated the sense of nationality and developed the naval forces of the race. Both Renaissance and Reformation had been anticipated by at least a century in England. Chaucer's poetry, which owed so much to Italian examples, gave an early foretaste of the former. Wycliffe's teaching was a vital moment in the latter. But the French wars, the Wars of the Roses and the persecution of the Lollards deferred the coming of the new age; and the year 1536, when Henry VIII. passed the Act of Supremacy through parliament, may be fixed as the date when England entered definitely upon a career of intellectual development abreast

with the foremost nations of the continent. The circumstances just now insisted on explain the specific character of the English Renaissance. The Reformation had been adopted by consent of the king, lords and commons; and this change in the state religion, though it was not confirmed without reaction, agitation and bloodshed, cost the nation comparatively little disturbance. Humanism, before it affected the bulk of the English people, had already permeated Italian and French literature. Classical erudition had been adapted to the needs of modern thought. The hard work of collecting, printing, annotating and translating Greek and Latin authors had been accomplished. The masterpieces of antiquity had been interpreted and made intelligible. Much of the learning popularized by the poets and dramatists was derived at second hand from modern literature. This does not mean that England was deficient in ripe and sound scholars. More, Colet, Ascham, Cheke, Camden were men whose familiarity with the classics was both intimate and easy. Public schools and universities conformed to the modern methods of study; nor were there wanting opportunities for youths of humble origin to obtain an education which placed them on a level with Italian scholars. The single case of Ben Jonson sufficiently proves this. Yet learning did not at this epoch become a marked speciality in England. There was no class corresponding to the humanists. It should also be remembered that the best works of Italian literature were introduced into Great Britain together with the classics. Phaer's *Virgil*, Chapman's *Homer*, Harrington's *Orlando*, Marlowe's *Hero and Leander*, Fairfax's *Jerusalem Delivered*, North's *Plutarch*, Hoby's *Courtier*—to mention only a few examples—placed English readers simultaneously in possession of the most eminent and representative works of Greece, Rome and Italy. At the same time Spanish influences reached them through the imitators of Guevara and the dramatists; French influences in the versions of romances; German influences in popular translations of the Faust legend, *Eulenspiegel*, and similar productions. The authorized versions of the Bible had also been recently given to the people—so that almost at the same period of time England obtained in the vernacular an extensive library of ancient and modern authors. This was a privilege enjoyed in like measure by no other nation. It sufficiently accounts for the richness and variety of Elizabethan literature, and for the enthusiasm with which the English language was cultivated.

Art, Letters, and the Drama.—Speaking strictly, England borrowed little in the region of the arts from other nations, and developed still less that was original. What is called Jacobean architecture marks indeed an interesting stage in the transition from the Gothic style. But, compared with Italian, French, Spanish, German and Flemish work of a like period, it is both timid and dry. Sculpture was represented in London for a brief space by Torrigiani; painting by Holbein and Antonio More; music by Italians and Frenchmen of the Chapel Royal. But no Englishman rose to European eminence in these departments. With literature the case was very different. Wyatt and Surrey began by engraving the forms and graces of Italian poetry upon the native stock. They introduced the sonnet and blank verse. Sidney followed with the sestet and terza rima and with various experiments in classic metres, none of which took root on English soil. The translators handled the octave stanza. Marlowe gave new vigour to the couplet. The first period of the English Renaissance was one of imitation and assimilation. Academies after the Italian type were founded. Tragedies in the style of Seneca, rivaling Italian and French dramas of the epoch, were produced. Attempts to Latinize ancestral rhythms, similar to those which had failed in Italy and France, were made. Tentative essays in criticisms and dissertations on the art of poetry abounded. It seemed as though the Renaissance ran a risk of being throttled in its cradle by superfluity of foreign and pedantic nutriment. But the natural vigour of the English genius resisted influences alien to itself, and showed a robust capacity for digesting the varied diet offered to it. As there was nothing despotic in the temper of the ruling classes, nothing oppressive in English culture, the literature of that age evolved itself freely from the people. It was under these conditions that Spenser gave his romantic

epic to the world, a poem which derived its allegory from the middle ages, its decorative richness from the Italian Renaissance, its sweetness, purity, harmony and imaginative splendour from the most poetic nation of the modern world. Under the same conditions, the Elizabethan drama, which in its totality is the real exponent of the English Renaissance, came into existence. This drama very early freed itself from the pseudo-classic mannerism which imposed on taste in Italy and France. Depicting feudalism in the vivid colours of an age at war with feudal institutions, breathing into antique histories the breath of actual life, embracing the romance of Italy and Spain, the mysteries of German legend, the fictions of poetic fancy and the facts of daily life, humours of the moment and abstractions of philosophical speculation, in one homogeneous amalgam instinct with intense vitality, this extraordinary birth of time, with Shakespeare for the master of all ages, left a monument of the Renaissance unrivalled for pure creative power by any other product of that epoch. To complete the sketch, we must set Bacon, the expositor of modern scientific method, beside Spenser and Shakespeare, as the third representative of the Renaissance in England. Nor should Raleigh, Drake, Hawkins, the semi-buccaneer explorers of the ocean, be omitted. They, following the lead of Portuguese and Spaniards, combating the Counter-Reformation on the seas, opened for England her career of colonization and plantation. All this while the political policy of Tudors and Stuarts tended towards monarchical absolutism, while the Reformation in England, modified by contact with the Low Countries during their struggles, was narrowing into strict reactionary intolerance. Puritanism indicated a revolt of the religious conscience of the nation against the arts and manners of the Renaissance, against the encroachments of belligerent Catholicism, against the corrupt and Italianized court of James I., against the absolutist pretensions of his son Charles. In its final manifestation during the Commonwealth, Puritanism won a transient victory over the mundane forces of both Reformation and Renaissance, as these had taken shape in England. It also secured the eventual triumph of constitutional independence. Milton, the greatest humanistic poet of the English race, lent his pen and moral energies during the best years of his life to securing that principle on which modern political systems at present rest. Thus the geographical isolation of England, and the comparatively late adoption by the English of matured Italian and German influences, give peculiar complexity to the phenomena of Reformation and Renaissance simultaneously developed on our island. The period of our history between 1536 and 1642 shows how difficult it is to separate these two factors in the re-birth of Europe, both of which contributed so powerfully to the formation of modern English nationality.

THE NEW EUROPE

It has been impossible to avoid an air of superficiality and the repetition of facts known to every schoolboy in this sketch of so complicated a subject as the Renaissance—embracing many nations, a great variety of topics, and an indefinite period of time. Yet no other treatment was possible upon the lines laid down at the outset, where it was explained why the term Renaissance cannot now be confined to the Revival of Learning and the effect of antique studies upon literary and artistic ideals. The purpose of this article has been to show that, while the Renaissance implied a new way of regarding the material world and human nature, a new conception of man's destiny and duties on this planet, a new culture and new intellectual perceptions penetrating every sphere of thought and energy, it also involved new reciprocal relations between the members of the European group of nations. The Renaissance closed the middle ages and opened the modern era—not merely because the mental and moral ideas which then sprang into activity and owed their force in large measure to the revival of classical learning were opposed to mediæval modes of thinking and feeling, but also because the political and international relations specific to it as an age were at variance with fundamental theories of the past. Instead of empire and church, the sun and moon of the mediæval system, a federation of peoples, separate in type, and divergent in interests, yet bound

together by common tendencies, common culture and common efforts came into existence. For obedience to central authority was substituted balance of power. Henceforth the hegemony of Europe attached to no crown, imperial or papal, but to the nation which was capable of winning it, in the spiritual region by mental ascendancy, and in the temporal by force.

That this is the right way of regarding the subject appears from the events of the first two decades of the 16th century, those years in which the humanistic revival attained its highest point in Italy. Luther published his thesis in 1517, 64 years after the fall of Constantinople, 23 years after the expedition of Charles VIII. to Naples, ten years before the sack of Rome, at a moment when France, Spain and England had felt the influences of Italian culture but feebly. From that date forward two parties wrestled for supremacy in Europe, to which may be given the familiar names of Liberalism and Conservatism, the party of progress and the party of established institutions. The triumph of the former was most signal among the Teutonic peoples. The Latin races championed by Spain and supported by the papacy fought the battle of the latter, and succeeded for a time in rolling back the tide of revolutionary conquest. Meanwhile that liberal culture which had been created for Europe by the Italians before the contest of the Reformation began continued to spread, although it was stifled in Italy and Spain, retarded in France and the Low Countries, well-nigh extirpated by wars in Germany and diverted from its course in England by the counter-movement of Puritanism. From the *autos da fé* of Seville and Madrid, the flames to which Bruno, Dolet and Palerino were flung, the dungeon of Campanella and the seclusion of Galileo, the massacre of St. Bartholomew and the faggots of Smithfield, the desolated plains of Germany and the cruelties of Alva in the Netherlands, disillusioned Europe of those golden dreams which had arisen in the earlier days of humanism, and which had been so pleasantly induced by Rabelais. In truth the Renaissance was ruled by no *Astraea rediit* but rather by a severe spirit which brought no peace but a sword, reminding men of sternest duties, testing what of moral force and tenacity was in them, compelling them to strike for the old order or the new, suffering no lukewarm halting between two opinions. That, in spite of retardation and retrogression, the old order of ideas should have yielded to the new all over Europe—that science should have won firm standing-ground and political liberty should have struggled through those birth-throes of its origin—was in the nature of things. Had this not been, the Renaissance or re-birth of Europe would be a term without a meaning. (J. A. S.)

While Symonds' article on the Renaissance, originally contributed to the 9th edition of the *Encyclopædia Britannica* remains the classical exposition of a certain view of the subject, more recent research has brought out other aspects of the matter. It is noteworthy, however, that in some important points the very latest investigators have returned to Symonds' conception of the Renaissance, from which historians of the generation immediately following him had departed.

Our continually growing knowledge of the middle ages has thrown the Renaissance into a very different perspective from that in which it was once viewed. Less and less are the centuries preceding the 15th seen as the "Dark Ages" in contrast to the sudden sunrise of modern times. Indeed, many scholars now speak of a Carolingian Renaissance in the 8th century, an Ottonian Renaissance in the 10th, and of the Renaissance of the 12th century, in order to emphasize the constant stream of light and progress throughout the millennium once regarded as a long night of gloom and decadence. On the other hand, many scholars have emphasized even more than did Symonds the extreme gradualness of the efflorescence of the Italian Renaissance and the long persistence in it of mediaeval and Germanic elements. The extreme position is taken by Mr. Henry O. Taylor, who is so impressed by the slowness of the transition from mediaeval to modern times that he would abolish the term "Renaissance" altogether. This proposal, however, has commended itself to few other scholars; there was a re-birth of the human mind in the 15th century, though it was not so sudden and decisive as once thought.

In another way our view of the Renaissance has been greatly modified by the economic historians who have stressed the material antecedents of the great political and intellectual movements of the 14th, 15th and 16th centuries. Symonds, like nearly all his contemporaries, wrote almost as if the change in the mental habit of the race were a first cause, unexplained by any alteration in social conditions. But it is now generally accepted that the intellectual change was but the natural result of material conditions altered by the growth of wealth, of commerce, and of city communities. The humanists and artists were dwellers in the cities and in the marts of trade; their patrons were largely found in the newly powerful bourgeoisie of the Italian and German cities. Of course the Renaissance had its intellectual as well as its material antecedents; it was produced by the happy creation in the commercial revolution of a wealthy and leisured class just at a time when discoveries and inventions were thrilling the mind of Western Europe with interest and curiosity. It was no accident that Individualism, humanism, and Italian painting attained their majority in the age which saw the invention of printing and the great geographical discoveries of Diaz, of Vasco da Gama, and of Columbus.

Of all the positions taken by Symonds that most subject to attack has been his assertion of the close connection and similar purpose of the Renaissance and Reformation. Like most historians of the 19th century, Symonds regarded them both as liberal movements, emancipations of reason so nearly alike that the Reformation might be called "the Teutonic Renaissance." Just as he was writing, however, Friedrich Nietzsche, basing his opinion on Janssen's *Geschichte des deutschen Volkes seit dem Ausgang des Mittelalters*, which represented the Reformation as a blight on German Catholic civilization, proclaimed that "the Reformation" was a reaction of backward minds against the Italian Renaissance"; and this view gained ground until it was adopted by Catholic historians like Lord Acton, Protestant historians like Ernst Troeltsch, and generally by the majority of scholars. They have pointed out that the humanists and Reformers came to blows, that the spirit of the Renaissance was largely secular and that of the Reformation intensely religious, that the former was tolerant and often indifferent and sceptical and that the latter was usually intolerant, devout, and sometimes superstitious, that the humanists were aristocratic and the Reformers democratic in method, and that Puritanism proved hostile to and often destructive of the artistic and pleasure-seeking interests of the Renaissance. In criticism of this view, however, it has been contended that the Renaissance was not, any more than the Reformation, consciously progressive; rather did both movements find their ideal in the past, the one in the golden age of Rome and the other in the primitive age of Christianity. It has been further shown that the humanists did little in principle to emancipate the reason from authority; they were closely bound by their own authorities in the classical poets and orators, and could only attack the schoolmen on the basis of the ancient pagans as the Reformers attacked them from the standpoint of the ancient Fathers. In conclusion one may say that neither movement was a conscious appeal to reason or an intentional step forward and away from the past, but that each accomplished, undesignedly, a great work of emancipation and that each created new cultural values.

BIBLIOGRAPHY.—The special articles on the several arts and literatures of modern Europe, and on the biographies of the great men mentioned in this essay, will give the details of necessity here omitted. Of general works, with bibliographies, may be mentioned Jakob Burckhardt, *Die Kultur der Renaissance in Italien*, called by Lord Acton, "the most penetrating and subtle treatise on the history of civilization that exists in literature" (Leipzig, 1st ed. 1860; 2nd ed., revised by L. Geiger, 1919; Eng. trans. by S. G. C. Middlemore, 1875); J. A. Symonds, *The Renaissance in Italy* (1875-88); Cambridge Modern History, vol. I, "The Renaissance" (1907); A. RENAISSANCE ARCHITECTURE. During the 15th, 16th and 17th centuries the structural and decorative elements of Roman architecture (*q.v.*), revived after long disuse, were adapted to the requirements of contemporary buildings throughout Europe. The column and the arch, the dome and groin vault, the arabesque and the rinceau, were conventions from which, in infinite combinations, architects developed their designs. The unity of centralized space and mass, the power of great scale and weight, the repose and completeness of definite and simple development of planes, passages and profiles, and the splendour of richly modelled and coloured surfaces, were the effects most often striven for. Yet Renaissance (*q.v.*) architects did not reproduce, even remotely, a single Roman building; the conditions of life had changed too much for Roman buildings to be practicable.

New Forms.—New and magnificent forms in structure, and in decoration applied to it, were developed. The dome raised on a drum, free from its abutments and crowned with a cupola, was one; when such a dome was raised, by means of pendentives, on four great arches, new and noble harmonies in spatial and mass composition resulted. Façades in which a classic ordinance is adapted to the basilican profile; barrel-vaulted or domed naves; campaniles which end in columned belfries; and vertical spires, encrusted with delicately modelled classic forms, are among the striking inventions of the period. The public buildings of the 15th and 16th centuries—the libraries, town halls, theatres and civic monuments—were utterly different from those of Rome. New combinations of the arch and the column, new rhythms in space, new arrangements in mass, new variations in ornament, had continually to be invented in order to fit the discovered architecture of ancient times to these new uses. Country houses—châteaux and villas, with their gardens—offered another field for adaptation and development; the design of public squares and streets and of buildings in ensembles another; and the vast palaces of the monarchs of France and Spain and England, and of the pope and the princes of the Church another. After three centuries of experiment and growth the Renaissance architect, in the façades of palaces, public buildings and houses, still expressed new ideas in the language of the column and the arch.

In the sixteenth century Europe was neither homogeneous nor centralized. Spain, Italy, Holland, England each had a native culture, a peculiar heritage from the mediaeval world, and each followed a course of development that was, at least in part, independent of all others. Spain, which had defended the Catholic faith against the Moors and which was flooded with the gold of Mexico and Peru, placed on her Renaissance forms a stamp very different from that of commercial and insular England. Monarchical France, rich with the heritage of the 13th century cathedrals, gave necessarily a different metamorphosis to the Italian tradition from Protestant and democratic Holland. Climate, building materials, prosperity, intellectual growth and inherited types of architecture such as the patio of Spain and the timber-roofed hall of England, the turreted chateau of the Loire and the balconied palace of Venice—these and many similar differences in civilization gave the Renaissance a distinctive colour, a special character in each locality.

Great Architects.—Finally there was the influence of individual genius. No period is so crowded with great architects and at no time have architects been so free to impress on their designs the imprint of a great personality. The Roman tradition has been called a tradition of formula and of precedent, yet no tradition has proved so flexible in the hands of a master. It lent itself with equal facility to the requirements of Bramante and of Bernini, of Christopher Wren and Juan de Herrera, of Mansart and of Alessi. It embraced within the limits of a single convention the delicate and gracious lyricism of Lescot, the agitated and passion-

ate declamation of Churriguera, the clear and vigorous rhythms of Inigo Jones, and the mighty harmonies conceived in the illimitable imagination of Michelangelo.

I. RENAISSANCE ARCHITECTURE IN ITALY

Owing to the small hold which the principles of Gothic architecture (*q.v.*) were able to obtain in Italy it is a fair generalization to look upon the architecture of that country from the 3rd century A.D. to the beginning of the 15th as a gradually falling struggle of the builders to retain Roman order and dignity in their undertakings. The early Christian period (see **BYZANTINE AND ROMANESQUE ARCHITECTURE**), no doubt produced, largely through the influence of Byzantine, much brilliant craftsmanship and a great deal of beautiful decoration, but on the whole it is safe to say that all this was applied to buildings in which the structure was decadent Roman. Later on, in what is generally called the Romanesque period the problems of Roman vaulting, now that the art of making concrete was lost, were solved by what to the Romans would have seemed the makeshift arrangement of surface ribs of stone in place of their own buried reinforcements. The clearness of the lines and surfaces of the Roman vaults were thereby interrupted, as were the wall surfaces, by a decoration of pilaster strips and thin arcading. It was the function then of the Renaissance builders—architects we may call them because they did their work with a greater foresight and seriousness of purpose—to bring back the Roman orderliness and precision. In the process they became no mere copiers of the antique. They invented many lovely forms and motives which had, as far as we know, no Roman precedents. As has often been pointed out there is far more difference between a Renaissance church and a Roman temple than between a Roman temple and a Greek one. On the other hand it must be admitted that, even more than in the other arts, there was a strong determination to recover Roman methods both of design and construction. Once the possibility of this was realized the remains of Roman buildings and monuments must have produced a great effect on the imagination. With their far greater scale, if not always greater mass, they must have seemed like the work of a race of giants, no longer to be shunned as something evil but instead, with the striking ambition of a time that produced figures like Galileo and Christopher Columbus, to be equalled and surpassed. The serious study of actual Roman buildings, which was started with Brunelleschi in 1403, gradually gave place, however, after the discovery of the works of Vitruvius, and their dissemination in numberless editions, to an academic interest in his system of proportions for columns, cornices and other details, which stifled real design until the latter was rescued and reinvigorated by Michelangelo and the other giants of the Baroque movement (see **BAROQUE ARCHITECTURE**). The history of the Italian Renaissance, as far as architecture is concerned, is the history of a school of ordered design, which receiving its initial impetus from the antique set out on a new and adventurous career of its own until it was finally bogged by misapplied scholarship.

Brunelleschi.—An appropriate date from which to start is therefore 1403 when Filippo Brunelleschi, a Florentine metal worker by trade and some 26 years of age, having left in the competition for the bronze doors of the baptistry, left his native town for Rome with the express purpose of studying the Roman remains in that city. The young Donatello, then 16, afterwards to be the famous sculptor, accompanied him "to hold the other end of the tape" as we should say to-day. They stayed away four years and on his return Brunelleschi, with the reputation his knowledge of Roman work gave him, persuaded the council to allow him to

finish the Duomo, which still lacked a covering to the great crossing. For this he designed his famous dome, the first great dome to be raised on a drum. A dome raised on a drum was not a Roman form; neither was Roman construction used; which shows that Brunelleschi's Roman studies had not fettered his imagination. The great raised dome, like that of St. Peter's at Rome, was to become one of the most magnificent and distinctive products of the Renaissance and this Florentine one at the start was one of the largest and boldest.

The more distinctive work of Brunelleschi in the new manner, however, is to be found in the smaller buildings that he carried on at the same time, such as the Pazzi chapel in the cloister of Santa Croce—the first completed ecclesiastical building of the Renaissance. It is a small structure, some 70 ft. square, containing an open loggia, an oblong main compartment (60 by 30 ft., approximately) and a square chancel with a square sacristy on either side. The loggia is a Romanesque barrel vault with coffering carried on six lofty Corinthian columns the centre bay of which is larger than the rest and the vault is there carried up on pendentives as a small dome. Above the entablature of the columns the exterior consists of a broad panelled surface and it and the entablature alike are boldly broken by a semi-circular arch joining the two groups of columns. Above this again is an open belvedere under the eaves of an overhanging tile roof and above again the main dome of the chapel. This composition then has no likeness to the façade of a Roman temple although in size it equals many of them. While using elements derived from Rome it is a light and graceful structure in which all the ordered parts of the design are made subservient to the main climax of the great central arch. The same remarks apply to the interior. The construction is very like that of the loggia, a dome intersecting a barrel vault. It is in white plaster, dark stone pilasters and entablatures outlining the architectural forms. Its note, like that of the façade, is lightness and elegance in which Roman forms and details have been used with a new delicacy. In place of the heavy tramp of Romanesque bays and piers we have here a building unified by its central dome and by its orderly arrangement of columns and pilasters, spiritualized and made light and beautiful by the purity of its lines and the delicacy and charm of its detail. It is a new thing neither Roman nor Romanesque, but nevertheless with Roman completeness and unity. The Pazzi chapel has been dealt with at this length because probably more than any other building of its time it gives the Renaissance outlook with its modern feeling for orderliness and perfection combined with the suggestion of Roman grandeur.

Types of Building.—The two chief types of building on which the Italian Renaissance was to found itself were palaces and churches. In mediaeval times the Italian cities were full of lofty stone palaces presiding courts. They were a feature of Italian urban civilization with its city states. Buildings with flat street façades almost necessarily have an orderly arrangement of windows. To such buildings, therefore, it was easy for the Renaissance architect, thinking in a Roman system of units, based on the regular setting out of colonnades and their superimposition, to apply his new ideas. The great overhanging eaves of the roof could be transformed to a crowning cornice, the pointed windows turned to semi-circular ones, the rough stonework reduced to a graded system of storeys, gradually approaching a clear ashlar face from which the main cornice could spring. Order was there already. All that had to be done was to introduce a higher sense of unity by seeing that every part bore some tangible relation to the whole. In this way we get palaces like Michelozzi's Riccardi and Majano and Cronaca's Strozzi in Florence in which the strength of the cliff wall is enhanced by contrast with fine detail and a higher sense of unity and power is reached.

The next stage in the development was the actual application to the wall surface of a series of pilasters recalling the Roman system of super-imposed colonnades. These were first used at the Rucellai palace in Florence by Alberti. The columns and their entablatures are here very tentative and are planted on top of the strong stone jointed face, which still dominates. A next step would be the grouping of such pilasters in pairs as at

the Palazzo Giraudi or the Cancellaria in Rome, both by Bramante. Following this idea through we have, in the more luxurious atmosphere of Venice, columns at each storey taking the place of pilasters and used in great profusion either singly or in pairs with one quarter of their thickness apparently buried in the wall. The palaces on the Grand canal offer many examples, but it will be noticed that even in the richest the wall plane is carefully preserved and the cliff-like face, however articulated, remains. Florentine palaces, however, were never to go beyond applied pilasters until the Baroque period (see BAROQUE ARCHITECTURE) arrived. Indeed, it shed even them and produced in the 16th century the stately palace in which all orders or columns, apart from those to windows or doors, are implicit. A Florentine architect, Antonio Sangallo, carried the idea to Rome with the Farnese palace from whence it has spread over the world.

The architectural quality of orderliness which produced the great palaces and stately churches of the Renaissance did not for a long time, however, destroy the lightness and fancy which the carvers, goldsmiths and painters who turned their attention to building brought to their new task. The smaller details of all early Renaissance buildings, such as wall monuments, balconies and screens in the churches, the furniture in the palaces, show, not only in Florence but in most towns in the north of Italy, a profusion of exquisitely drawn and modelled ornament based on classical motives but used with great freshness and originality. A Renaissance doorway would be applied to, or carved on, a Gothic church, as at Como cathedral, and it would not only form a delightful composition in itself, often in several planes, but would make an extraordinarily rich and delicate piece of decoration against its coarser surroundings. In such work, especially in Lombardy, pilasters and architraves were filled with delicate arabesques. Indeed, in many minds this rich highly carved detail constitutes the chief characteristic of Renaissance work. Those who think this, however, mistake the flower for the tree. The organic relation of all parts to each other and to the whole, based on the Roman system of axial relationship while making use of simple Roman shapes, is the essential trait.

Development.—From Florence the movement of architecture "in the antique manner" spread to every town in Italy and, as in painting, each town produced its school centred round one or two first-rate artists. In Milan, Bramante carried out his early but very accomplished work before Rome absorbed him for St. Peter's. His church of Santa Maria delle Grazie piles up in the simple logical way of applied masses, which the Renaissance always implied, while its detail remains fanciful and in parts Romanesque in character. A great difference between Renaissance architecture in Italy and similar work in France or England is that in the former country the movement attacked from the beginning the plan forms and the structural shape of buildings, whereas in the latter countries it began by an application of the new fashioned detail to buildings which remained Gothic both in plan and structure.

The first half of the 16th century saw the migration to Rome of the best artists from Florence, Milan and other centres attracted by the superior opportunities that city offered under such patrons of the arts as Popes Julius II. and Leo X. Even the sack of Rome in 1527 did not stay building activities. It was there, under the shadow of the great monuments of antiquity, that the full use of the Roman orders (see ORDER) was recovered but without any attempt at imitating Roman buildings. This culminating period produced no Parthenon as a climax. The great scheme for St. Peter's, however, started on its career at this time with magnificent and entirely novel plans for the Greek cross building piling up to a great central dome. Bramante laid down the general lines and began the actual structure. Sangallo and Peruzzi followed with modifications of his plan and finally after further vicissitudes Michelangelo took hold of the work and carried it through. His great structure rightly belongs to the Baroque period, though the basic idea on which he worked was that of Bramante and the earlier architects mentioned, and though the building as far as its orderly procession of parts both in plan and section is a Renaissance structure. If, however, St.

Peter's, by the majestic simplicity of its major parts and by its great dome—the best example of the finest architectural invention of the Renaissance—has a claim to a place in that movement it is in smaller buildings in Rome like the Farnese and Massimo palaces, by Antonio Sangallo and Baldassare Peruzzi respectively, that the full flavour of the culminating period is to be tasted. In them it is to be found not only complete mastery of plan, by which all apartments flow together to make a whole out of well-shaped units, but both exteriors and interiors that show a similar mastery of classical detail while maintaining the traditional form and expression of an Italian nobleman's house.

From Rome this mastery of classical forms and their adaptation to modern purposes, which makes Italian Renaissance architecture of importance to us to-day, flowed back to the provincial towns. In Bologna, his native city, Peruzzi built a number of stately houses simple in composition yet completely unified and with detail almost Greek in its refinement. In Verona, Sannicchi, architect and military engineer, fortified the town, his birthplace, and gave to the palaces he built in it and in Venice qualities of strength and scale which are unsurpassed in the works of any master. Through his military engineering work he apparently learnt economy of means in obtaining his effects; for instance, in his series of great gateways through the walls of Verona he reduced cornices to mere bands except in the central portion of his design in order to enforce his climax. His work shows a strength, grandeur and scale that surpasses in its finest qualities Roman work itself. His Grimani palace on the Grand canal at Venice is the strongest and most impressive of those built during the Renaissance.

In the library of St. Mark's at Venice, by Jacopo Sansovino, architect and sculptor, who like so many of his profession started life in Florence, the culminating period of the Renaissance reaches a note of greater richness if not greater grandeur. In its façades of two main stories, each with fully developed order and arch in the Roman manner, Sansovino succeeded in combining these stores into one whole by means of an enlarged frieze to the upper order, by low thin steps to the lower and by a crowning balustrade with statues. By the depth of his reveals and the doubling of his subsidiary order in the thickness of the wall, by his overlay of rich, sculptured ornament, he produced here perhaps the richest building before the full advent of the Baroque period. The building, nevertheless, with the assistance of the broad surfaces of its unfuted columns, carries its richness with complete assurance and dignity. There is no feeling that it is overloaded. It is no wonder, therefore, that its façades have formed the main motives of many an opera house and theatre throughout the world, including the most famous, Garnier's great opera house in Paris.

Palladio and Vignola.—The freer use of the orders was carried a step further still by Andrea Palladio who practised chiefly in the small town of Vicenza in the second half of the 16th century but whose name nevertheless became more widely known than that of any of his contemporaries. Indeed, his use in his later buildings of a single order of columns or pilasters as the governing motive for a façade gave rise to the term Palladian in English architecture. So great was his fame, assisted by his book, that Vicenza became a centre of pilgrimage for English architects in the 17th and 18th centuries from Inigo Jones onwards. His written work like that of Serlio, Vignola and other Italian architects who wrote on their art, followed Vitruvius and was largely concerned in establishing a system of proportions for the orders and their accessories. Palladio's buildings, however, are better than his writing. The Palazzo Consiglieri, for instance, facing his more famous basilica, where he used a powerful Corinthian order of four columns running up the face of the building, with the cornice returned round each column as in the form of Nerva, shows the hand of the master in the modelling of his small building so that its scale throughout lives up to the giant size set by his columns. In the comparatively poor town of Vicenza to obtain the great effects he sought he was reduced to building in brick covered with stucco and no doubt it was the fluidity of this latter material which gave to his buildings their slight

sense of unreality. His stone churches in Venice including the great composition of San Giorgio Maggiore with church, campanile, monastery, harbour and lighthouses in one scheme, facing the town across the lagoon, are sounder architecture because they are sounder building.

Giacomo Barozzi da Vignola, commonly called Vignola, was much the same type of architect as Palladio and, like him, published his designs and his rules of proportion. As Palladio ruled in England so Vignola did in France. Working chiefly in Rome and the neighbourhood during the latter half of the 16th century he stood like Palladio as a bulwark against the increasing power of the Baroque. Michelangelo seems to have little influence upon him, except perhaps in the dramatic quality of his compositions, such as that of his great pentagonal villa at Caprarola and the magnificent climax achieved in his small one for Pope Julius III. in the Borghese gardens.

With these two men, Palladio and Vignola, the work of the Italian Renaissance may be said to have reached the utmost limit of revived and revived Roman architecture. The motives and orders of the Romans could be exploited no further. For fresh advance it required the genius of Michelangelo and the other founders of the Baroque, who, lifting Italian architecture from its orderly Roman basis of assembled units in plan and elevation, gave it new freedom by considering structure rather as so much plastic material for the fancies of the modeller than so much cubic content in rooms and walls for the imagination of the architect. While, however, the Baroque for a time conquered the known world, with perhaps the single exception of England, as new problems arose in later centuries calling for new solutions the whole of the Western world, including America, turned again to the architecture of the Italian Renaissance, for refreshment, for guidance and, most important of all, for sanity and clearness of expression.

II. RENAISSANCE ARCHITECTURE IN SPAIN

Towards the latter part of the 15th century, the decorative motives of the Italian Renaissance began to make their appear-

ance in the ornamentation of Spanish buildings. The prosperity which followed the conquests of Peru and Mexico and the national exaltation which accompanied the end of the long wars with the Moors had found expression in the construction of great Gothic cathedrals, but for the decoration of these, and especially for the construction of minor works of architecture such as tombs, altars, retablos and rejerías (iron screens), Italian artisans were employed. These artisans, bringing with them many examples of Renaissance design, taught their art to the Spanish and Moorish craftsmen. The patronage of wealthy ecclesiastics who, travelling in Italy on some business of the Church, had fallen under the spell of Italian art, gave an added impetus to this new school of ornamentalists. From the chapels of the cathedrals the new style was introduced into the palaces of the archbishops and into the universities and hospitals established by the Church; the wealthy families of Burgos, Toledo and Salamanca soon adopted it for the decoration of their patios and the façades of their houses; and by the second decade of the 17th century it had become the accepted style of ornament throughout Spain, profoundly modifying the character of Spanish architecture.

Plateresque.—This decoration, which in its delicacy of scale and the exquisite perfection of its workmanship resembles silversmith's work—the work of artisans rather than of architects—has been called *Plateresque* (from *platero*, silversmith). The motives used are the arabesque, the niche, the grotesque, the candelabrum shaft, the paneled pilaster and the richly moulded entablature; and with these Italian forms there are mingled the geometric patterns inherited from the Moors and, not infrequently, Gothic forms such as the pinnacle, the crocket, cresting and the pierced balustrade. Moorish influence is felt, also, in the use of elaborate wood carvings, especially on the ceilings which are splendidly enriched with carved ornament and colour, and in the use of tiles, in superb coloured patterns, for walls and for stairs. Gothic influence survives in the occasional use of the ribbed vault. The use of the undraped human figure is infrequent except in the forms of children, but representations of animals in action, accurately observed and vigorously executed, are used in great profusion. Heraldry is also a source of many ornamental enrichments.

The exuberance of ornament, the fine craftsmanship and the refinement in modelling, in line and in the distribution of light and shade, are the architectural expression of a wealthy and proud aristocracy, which had discovered in Italy a new vocabulary of pleasure-giving forms. These forms were employed, oftentimes, with little understanding of their relation to structure; nor were they used, as in Italy, to give accent and significance to a composition in mass or space. They were used rather to enliven and enrich the textures of walls—an embroidery applied to surfaces—as if the house, or the tomb, were an added garment worn by its owner to express his taste and his importance. Like the costumes of the time, the buildings are embellished with rich patterns, applied with an exquisite tact and with a fine feeling for rhythm and contrast in spacing. The masterpiece of the period is undoubtedly the Ayuntamiento, or city hall, of Seville (1517-33), a building whose ornament is not excelled in Europe in fertility of invention or in facility of execution.

Second Phase.—The Plateresque architecture in Spain resembles the 15th century architecture of Lombardy and Venetia, and, like it, was succeeded by a colder and more monumental manner of building more correctly based upon Roman precedents. This change was due in part to the increasing knowledge of Roman art and to an admiration for the splendid monumental achievements of the 16th century masters, Bramante, Sangallo and Sanmichele, newly revealed to Spain. Her armies had overrun Italy; she had taken, and sacked, the city of Rome itself. But the change is also due to a change in the temper of the Spanish aristocracy. An architecture that was merely an embroidery applied to buildings could not, however lovely in itself, satisfy men who were masters of the world and who desired to express in an enduring form the grandeur and permanence of the political fabric that they had created. The colder and more abstract architecture of ancient Rome, vast in scale and in weight, an architecture, not of ornament

but of mass and of proportion, seemed more in keeping with the arrogant imperialism of Charles and Philip.

At any rate when these monarchs had extended their power over Spain, the Empire, Holland, Naples, Burgundy and America, Renaissance architecture in Spain entered, quite abruptly, its second phase. Monumental building succeeded ornamental. Architecture became once more a form-giving art. Buildings seem no longer to have been addressed to the social spirit of man, to seek to charm, to become a pleasing amenity in civic and ecclesiastical life; rather they seem to have been intended to overawe, to express in plastic form the energy and might of a stupendous Government. The palace built by Charles V. at Granada is a fine example of this political architecture. A part of the Alhambra was destroyed to make room for it. One regrets, of course, the oriental palace, full of sensuous charm and aristocratic loveliness, but the newer palace is not less beautiful. Still more impressive is the great Escorial (1560-84), a vast monastery built around a votive church and a mausoleum. This granite pile, which measures 675 ft. by 530 ft., achieves a majestic and awe-inspiring character by sheer size and weight. The grandeur and consistency of the remarkably unified design, the dramatic setting against the mountains and above the plain of Madrid, make of this monument a sublime symbol of the union of Spanish power and Catholic faith. The interior of the great cathedral of Granada, the Lonja, or exchange of Seville, and the hospital of San Juan Bautista, Toledo, are other examples of this second phase of the Spanish Renaissance, which are not unworthy of comparison with the best work of contemporary Italy. This phase did not last long beyond the close of the 16th century. (See BAROQUE ARCHITECTURE.)

Churrigueresque.—An architecture more congenial to the artistic spirit of Spain than the Plateresque, that of Francisco and Borromini appeared in the early part of the 17th century. It is characterized by a free plastic handling of masses, a broken or undulating skyline, an irregular, capricious distribution of light and shade, and a vast profusion of ornament; structure, geometric form and classic precedent are smothered under a lavish encrustation of luxuriant detail. At times this detail recalls that of the Plateresque; more often it differs from it altogether. It is bolder with far greater depths of broken shadow and vigorous projections; it is more fluid, the forms and planes melting into each other in rounded forms and an intricacy of curved lines; and there is lacking altogether the delicacy of line and shadow and the exquisite refinement in modelling that give distinction to the plateresque. The joyousness, the youth, of the early 16th century was replaced by a self-conscious and sophisticated spirit. Architecture was not, as in the Plateresque, a source of direct sensuous enjoyment; it was a language that attempted to translate passion and mysticism into plastic forms. The vocabulary of this new language is like that of Baroque Italy: there is the same prodigal use of volutes and consoles, of broken and scrolled pediments, of twisted columns, of reversed balusters and of elaborately modelled finials. The cartouche, enmeshed in a fantastic frame of volutes and scrolls, and the human figure, emotionally rendered and set in a niche, are characteristic forms of ornament, and there is a lavish abundance of flowers, of modelled draperies, shells and festoons, often executed (in an altar or retablo) in onyx, lapis lazuli, bronze or some other richly coloured material. This Baroque style in Spain is often called the Churrigueresque, from the name of its most successful practitioner, José Churriguera. It reaches its fullest development in altar-pieces and in the decoration of doorways. The west front of the Cathedral of Marcial, although not completed until the 18th century, is a characteristic example of the Spanish Baroque.

III. RENAISSANCE ARCHITECTURE IN FRANCE

It has become customary to include under the classification of Renaissance architecture all the architecture produced in a country after the Graeco-Roman revival in Italy from the 15th century to the end of the 18th. In the course of three centuries, as must be clear, the types of buildings, their planning and their construction—i.e., all that is vital and fundamental in the character of architecture—must vary widely, to meet the demands of changing social systems; and thus the only characteristic common to such dissimilar types of architecture as, for instance, that of the time of Francis I. and that of the period of 1750, is the employment of the classic orders as elements of the decorative design. Bearing this in mind, then, the following divisions for the periods of French Renaissance architecture are essential:

Renaissance Proper (1475-1610).—Covering the period from the introduction of the Italian-revival classicism through the reigns of Charles VIII., Louis XII., Francis I., Henry II. and his successors, up to 1589, and including, as a transitional period, the period of reconstruction, after the religious wars, of Henry IV. (1589-1610).

Seventeenth Century, Baroque and Academic.—Covering the period of the development of French classic art, from its formation in the first half of the century (reign of Louis XIII., 1610-43) through 1660, when the personal influence of Louis XIV. (1643-1715) was dominant, and up to about 1700.

Eighteenth Century, Rococo and Classical Reaction.—Covering the last phase of the Louis XIV. period, the Regency, and the return, in the second half of the century, to the more academic style which terminated at the Revolution.

Renaissance Proper (1475-1610).—In the last quarter of the 15th century the importations of Italian works of art increased steadily; the French nobles ordered funeral monuments and cabinet work in Italy, and brought over skilled Italian workmen; the military expeditions into Italy had familiarized many Frenchmen with the Italian Renaissance and created the desire to produce at home the masterpieces admired abroad. But the Gothic art (*see* **GOthic ARCHITECTURE**), though dying, was by no means dead, and Gothic edifices continued to be built as late as the 17th century. The Italian influence, therefore, did not find a clear course, but asserted itself simply in the replacement of certain Gothic forms of decoration by Renaissance details. A compromise was thus effected between the old and new traditions, and the work of building went on as before under the guidance of the French master-builders (heads of the various guilds). The plan of a building, and its vaults, high roofs, dormer windows and decorative chimneys followed the Gothic tradition; while on every space suitable for carving appeared the arabesques of the Italian pilaster, the medallions with profiles of the Caesars, and the capitals, mouldings and ornaments inspired by Roman precedent. This dualism of structure and ornament is the essential characteristic of French Renaissance architecture.

Authorship of Buildings.—The authorship of the principal buildings of this first period has been the subject of long and violent controversies; but the argument of those who attribute it almost exclusively to Italian architects is not overwhelmingly convincing. This argument runs to the effect that "the ignorant master-builders whose names appear on the records were incapable of producing the work of the early Renaissance." But these same "ignorant" master-builders had been, and were still, building masterpieces of Gothic architecture. The work of French designers is clearly marked by its *fluency* in the prevailing Gothic construction, and its *adaptability* to the Italian vocabulary of classical architecture. To mention the names of Philibert de l'Orme, Pierre de Chambord, and others, is to mention the names of the French architects who, by their knowledge of the very rudiments of the art of which they were not conscious, and by their intuitive grasp of the principles of the Gothic style, were able to produce the work of French Gothic architecture.

Buildings.—From the end of the 15th century to the reign of Francis I., the building of Gothic in France was continuing by the introduction of Italian ornament, and in the work of a transitional period. Then, in the reign of Francis I., the Gothic elements of the façade were supplanted by new features. As yet there was

no clear understanding of the essence of classic architecture, i.e., unity and purity of form, and a definite relationship of all the elements of a composition to a common standard of measure, but there was an effort to attain harmonious distribution of these elements. The king was building, or remodelling, Villers-Cotteret, Fontainebleau, Chambord, Madrid, St. Germain, La Muette and Blois, and, at his example, Renaissance forms were adopted for Écouen, Ancy-le-Franc, St. Pierre at Caen, St. Eustache and St. Étienne du Mont. The nobles, with the necessity for security decreasing as the king's power grew, abandoned their old fortresses or transformed their family seats by large windows pierced in the towers, and by the addition of new wings. The plan of city residences remained Gothic, however, with the master's dwelling standing between the garden and the courtyard in front; the services were arranged at the sides of the courtyard, and the house faced the garden side; this disposition *entre cour et jardin* remained a favourite in France as late as the 19th century. Within the dwelling, the walls—unless covered with tapestries—still showed their masonry, and the rooms still had Gothic timber-work ceilings, but the huge fireplaces were adorned, on their pilasters and niches, with the new arabesques (e.g., chimneys of Blois and Hôtel d'Alluye).

By the middle of the 16th century, the Gothic finally disappeared from domestic architecture, although in religious architecture—where evolution is always slower—the planning still remained flamboyant Gothic (e.g., Brou, Troyes, transepts of Beauvais, and St. Nizier at Lyons). Then, in the period from 1547 to the beginning of the reign of Henry IV. (1589) there was an amazing development—the antique system of proportions was mastered. The use of the Roman orders became general, but they were adapted to conditions so different from those prevailing in Italy that they acquired a character peculiarly French. Such innovations as open stair-wells, alternation of ordinances of pilasters and projecting cullminated motives, and the French order of Philibert de l'Orme, are contributions to the architectural repertory that were widely used later. The *giant order*, embracing two storeys, was developed simultaneously in France and in Rome.

The names of three architects dominate this period: Philibert de l'Orme (1510-70), who built the Château d'Anet, part of Chenonceau and the earliest portion of the Tuileries; Pierre Lescot (1510-78), who built a portion of the Cour du Louvre; and Jean Bullant (1525-78), who built at Fère-en-Tardenois, at Chantilly (Château), additions to Écouen, and a part of the Tuileries. With the passing of this generation of great architects, the brilliant period closes,—having lasted for only 20 years,—and is succeeded by a period of sterility, due to religious wars and anarchy.

Reign of Henry IV. (1589-1610).—The architecture of the short interval between the time of the entrance of Henry IV. into Paris and his death (1595-1610), may be called the architecture of a reconstruction period. It is characterized by a simplicity and effectiveness attained, not by the use of expensive ornament, but by brick and stone employed in the old French tradition, the façades being decorated by quoins of rustication instead of by the orders—a somewhat severe treatment which was softened by the mellow colour of the walls under the firm silhouette of the slate roofs. The outstanding contribution to architecture, however, was the king's great undertaking to remodel the city, which had grown up haphazardly—an undertaking such as had not been attempted since the days of imperial Rome. To achieve his end, he made laws regulating the heights of buildings and the paving and widening of streets, and prohibiting the overhanging upper stories of the middle ages. Finally, by the contribution of such schemes of civic planning as the Place Royale (now the Place des Vosges) and the Place Dauphine, he inaugurated a school which, after reaching its apogee in the 18th century, furnishes models for city-development to-day. Examples of this period are the important additions to Fontainebleau, the château of St. Germain-en-Laye and portions of the Louvre.

Seventeenth Century.—At the beginning of the century, there was an unprecedented activity in building; the long period of wars had brought about the usual changes in private fortunes, and the "nouveaux riches" had to provide themselves

with splendid habitations. The architecture of this time excels in the planning of town residences (hôtels), with their admirable arrangements of the cour d'honneur, service courts and noble garden elevations. The larger houses retained the "galeries" of the earlier Renaissance for the display of art treasures. The country estates are notable for their fine gardens, decorated with statues, basins and balustrades. In ecclesiastical architecture, the Jesuits cast the weight of their influence in favour of the adoption of Renaissance forms, and the churches and chapels designed by members of their order are inspired by the Gesù and the 16th century Italian examples (e.g., St. Paul and the Novitiate in Paris). To the influence of the Jesuit architecture and that of the Italian Baroque, rather than to the Flemish, may be ascribed the exuberant ornamentation prevalent in the early part of the century. Architects of the first rank were numerous, among whom the first is François Mansart (1598-1666), by far the greatest architect of his time, and, according to Blondel (a competent critic of the 18th century), "the most skillful architect France has ever produced." Among other notable works he designed the wing added by Gaston d'Orléans at Blois, with its magnificent stairway, the additions to the Hôtel Carnavalet with their exquisite refinement of detail, the Château de Maisons and the Val-de-Grâce, a masterpiece which one has only to compare to St. Eustache, built 50 years before, to realize that French architecture had reached maturity. The palace of the Luxembourg, by Salomon de Brosse, the magnificent composition of the town and palace of Richelieu, the chapel of the Sorbonne, by Le Mercier, the Château de Tanlay (Burgundy), by Pierre le Muet, with its beautiful park, antedating the compositions of Le Nôtre, and finally the work of Louis Le Vau, who created the style of Versailles and Vaux-le-Vicomte, of the Hôtel Lambert and the Collège des Quatre Nations, and who represents the transition from the period of Louis XIII. to that of Louis XIV., are some of the outstanding compositions of the early 17th century.

Louis XIV. Period.—The *grand monarque* placed the artists of his time under a discipline administered strictly by Colbert and Le Brun. The Academy of Painting and Sculpture was re-founded in 1666 and the Academy of Architecture created in 1671. There followed a reaction from the empiricism of the preceding period, strengthened by the reverence of the academies for their classic doctrines, and by the king's disdain of foreign influences. The academies were as suspicious of artistic independence as the king of political heterodoxy. The striking feature of this period is a curious contrast between the classic composition of exteriors, free from the earlier experimental fantasies, and the elaborate ornamentation of interiors. There was a simplification both of the masses of a building, and of outward ornament, even to the silhouette of the roofs. The combining of few elements with unerring taste resulted in a stately dignity of proportion that lends even to the most unambitious work in provincial towns the noblesse of the greater constructions. On the other hand, the interiors were often overloaded with decoration. Le Brun, the court painter from 1664 to 1690, was in full authority at Versailles; a great decorator, he had the weaknesses of this aspect of his talent. Thus, refinement and intensity of expression were often sacrificed in the attempt to combine architecture, painting and sculpture into a single homogeneous effect.

Among the principal architects of the time, are Claude Perrault (1618-83), who, besides the Porte St. Antoine, and the Observatoire, designed the three façades of the Louvre which have been praised and attacked beyond all measure, and the excellence of which is readily seen by a comparison with Bernini's project for the same work; François Blondel (1618-86), who designed the beautiful Porte St. Denis; Jules Hardouin Mansart (1646-1708), architect of Marly, the Grand Trianon, Place Vendôme, Place des Victoires and the "Dôme des Invalides," and who designed all the work at Versailles after 1676; and Libéral Brunt (1637-97), whose simple, powerful architecture may be seen in the Hôtel des Invalides and La Salpêtrière. A résumé of 17th century architecture would hardly be complete without a mention of Le Nôtre (1613-1700), who brought to its highest development the composition of the formal garden.

Eighteenth Century.—The change that began to make itself perceptible in the last period of the reign of Louis XIV., and up through the first half of the succeeding century, is the striking simplification of exteriors, coupled with a still more striking change of interiors. The classic doctrine, with the orders, is still asserted in the designs of the façades; but there appeared a bolder use of blank surfaces, relieved by chains of rustication, and more restraint in the use of mouldings. Thousands of houses of this period are still to be seen, with quiet elevations whose harmonious proportions are their only bid to attract attention, and with skillful interior planning which still serves as a model. The treatment of these 18th century interiors forms a striking contrast with the Baroque splendours of the heyday of Louis XIV. A reaction had set in against the conservatism, and the theatrical pomp of the 17th century, in which people moved like actors on a stage; the new tendency was toward greater freedom in the adaptation of the classic formulas, and lightness and elegance of effect, and intimacy. Even at Versailles, stately apartments were broken up into groups of smaller rooms, and houses were planned with corridors and an arrangement of rooms convenient to their uses. The wood panelling, which replaced the marble inlay of palaces or the bare walls of simpler dwellings, was treated as woodwork, with a scale of moulding and decoration suitable to the material and without imitation of stone architecture motives. Fabric and paper were introduced as wall coverings; the ceilings were no longer designed to imitate vaulting—the open beams and joists disappeared and plasterwork was treated frankly as such. The stairways were decorated only by their railings of admirably wrought ironwork. In these interiors there is a complete emancipation from Græco-Roman motives, pilasters, cornices, etc. The curved line prevails. It is the style of the Rococo.

The examples of the architecture of this period are so numerous that only a few can be mentioned here: e.g., the stables of Chantilly, and the Hôtel Biron by Aubert, la Malgrange (Nancy) and the Hôtel d'Amelot by Boffrand, the Palais Bourbon, by Giardini and l'Assurance. The work of public buildings and city planning counts in its first ranks the admirable ensemble at Nancy (Places Stanislas, de la Carrière and du Gouvernement) by Boffrand and Héré de Corny, the bridges at Nantes and Blois by J. J. Gabriel, the Place Royale at Bordeaux (Gabriel), and the Place Bellecour at Lyons (De Cotte). The religious architecture is exemplified by some imposing monasteries, which acquire with the excellent qualities of the domestic designing a certain touch of worldliness. Examples are St. Etienne at Caen, St. Ouen at Rouen, and the bishops' palaces of Toul, Verdun and Strasbourg.

Second Period.—Madame de Pompadour and her artistic advisers, such as Cochin and M. de Caylus, the archaeologists, and the architects Gabriel and Blondel had never looked with favour upon the infringements of the antique formulas that were committed in the Louis XV. period, and the new discovery of antiquities at Herculaneum and Pompeii infused the supporters of the classic doctrine with fresh conviction. Toward 1750, then, the fashion reverted to the close imitation of a Græco-Roman style, newly baptized "à la Grecque." De Caylus's "*Recueil d'Antiquités*," published in 1762, Leroy's "*Ruines des plus beaux Monuments de la Grèce*" (1754), Soufflot's work on Pæstum, and Piranesi's engravings, encouraged and facilitated the return to antique example by giving more precise documentation. Among the representative works of the architecture of the time are the Petit Trianon, the Ecole Militaire, the wings of the entrance court and the opera at Versailles, and the Place de la Concorde, by J. A. Gabriel, the Hôtel-Dieu at Lyon, the church of Ste. Genevieve at Paris, now the Pantheon, by Soufflot, and the works of Antoine, Mique, Ledoux, Victor Louis, Rousseau, (theatre of Bordeaux, mint and Palais de Justice at Paris).

IV. GERMANY, FLANDERS AND HOLLAND

In the 16th century, Germany resisted, more than France or Spain, the Italian influence. The classic spirit in art was apparently less congenial to her civilization, which lacked the Latin basis, and she had not suffered, like France and Spain, the disintegrating influences of a long destructive war which, by weakening the mediaeval and national traditions, had prepared the way for a new and alien art. The Italian motives appeared sporadically—for example, in a Florentine belvedere built in Prague in 1536 and in the Lombardesque wing of the castle at Heidelberg, built in 1556—but the Renaissance had to await the end of the 16th century to win a wide acceptance north of the Alps.

About 1580 the Baroque forms of Alessi were introduced into Germany. These forms, which were understood more as a system of decoration than as elements in mass composition, became immediately popular in the South German cities: broken pediments, scrolls, consoles, cartouches, the human figure placed in a niche, began to appear in profusion on the façades of churches and houses which in composition were still mediaeval. This fusion of Gothic picturesque with the sophisticated Baroque ornament gave to this first phase of German Renaissance an altogether unique character. The great stepped gables of town houses and the transept ends or façades of churches, wholly mediaeval in mass and line, flower out at the top into a rich encrustation of modelled form in which all the elements of classic architecture seem to be melted together. Examples of such designs are the Merlenkirche, at Wolfenbüttel, the Gewendhaus at Brunswick (1592) and the Pellerhaus, in Nuremberg (1625).

After the Thirty Years' War, which ended in 1648 and devastated the greater part of the Rhine countries, German Renaissance architecture entered a new phase. The Baroque spirit gained a more complete ascendancy and in many localities mediaevalism entirely disappeared. Naturally the Baroque was more completely accepted in the southern and Catholic countries where Italian architects, brought into Germany by the Jesuits, built, or helped to build, many churches and palaces. Along the Rhine the French influence was felt, but it was not until the 18th century (see MODERN ARCHITECTURE: 18th and 19th Centuries) that Germany turned directly to France for artistic inspiration. In that century the architecture of Versailles was widely imitated in the German courts, achieving there a compromise, or fusion, with the Italian Baroque. The result was a vigorous and original style, often piquant and full of that element of "surprise" which is a result of Baroque freedom and movement.

Germany, having a larger number of capital cities—there were more than 300 in the 16th century—developed a greater variety of local styles than any other country. Vienna was of course the most important centre. The relief that was felt when in 1685 the Turks were driven from before her walls, the prosperity fostered by Leopold I. and Charles VI., and the renewed faith of the Catholic reaction, found expression there in a series of remarkable monuments. Fischer von Erlach and Lukas von Hildebrandt, the two great architects of Vienna, transformed the mediaeval city, as Bernini had transformed Rome, with fountains and public places, with majestic churches, vast palaces and astonishing gardens. In their hands the exuberant Baroque, touched with an oriental fantasy, reached a magnificence altogether consonant with the gorgeous imperialism and the fervid poetry of the times. The Karlskirche (1717-37) and the Hofbibliothek (1736), by von Erlach, and the Belvedere (1713-16), by Hildebrandt, are the most famous and perhaps most characteristic examples of this Viennese Renaissance.

After Vienna, the smaller courts of Dresden and Munich furnished important opportunities for the Renaissance architect. In Dresden, Pöppelmann (1662-1736) built the court of the Zwinger palace (1711-22), an extraordinary assembly of fantastic pavilion, bizarre planting and agitated sculpture. The Frauenkirche, in Dresden (1726-43), by George Bähr, is an original, free and virile design, perhaps the greatest achievement of the German

Renaissance. In Munich, where the Italian architect Agostino Barelli had built a Neapolitan church, the Theatinerkirche (1667-75), the Wittelsbachs employed the French architect, François Cuvilliers, to add to their somewhat grandiose palace the altogether delightful Residenz-theatre (1752-60). Salzburg, with its cathedral (1614-34), its University church, and its Mirabel-Schloss, is one of the loveliest of Baroque towns; Prague has the great Wallenstein palace (1673-1730), the work of the Italian Marini, as well as the more Teutonic Kinsky palace, the work of the talented architect Kilian Ignaz Dientzenhofer; and in Potsdam, where, under Frederick the Great, French influence is most felt, the palace of Sans Souci (1716) achieves a delicacy and graceful freedom certainly not excelled in contemporary France.

To this architecture of the city and court there is added the architecture of the monasteries. Placed picturesquely among the hills of the Danube or the Rhine, these vast buildings offered opportunities most congenial to the spirit of 17th century architecture. Melk (1707-36) is perhaps the most impressive; a colossal mass which commands the Danube from the top of a mighty cliff and throws against the sky a superb tangle of modelled spire and dome.

In Flanders and Holland the development of architecture in the Renaissance was not essentially different from that of North Germany. The Jesuit influence was felt in Flanders and the development of churches of the II Gesu type, such as the church of St. Michael, in Louvain (1650) was parallel to the contemporary development in South Germany and France. In Holland, as in Germany, the stepped gables of the town houses were transformed by the addition of Baroque detail but the use of brick and of quoins and the need of economy often gave them a more sober aspect than their Germanic cousins. At times the French influence was felt, as, for example, in the Hôtel de Ville in Antwerp (1561), a design in which superimposed columns enframe round-arched windows with a gracefulness and distinction in detail that recalls the work of Lesot.

V. RENAISSANCE ARCHITECTURE IN ENGLAND

The Renaissance architecture of England may be conveniently divided into two phases which correspond roughly to the 17th and 18th centuries, to the period of the Stuarts and the period of the Georges. In the first phase the genius of two great architects, Inigo Jones and Christopher Wren, created for England a new system of design, based upon elements imported from Italy. In the second phase a host of other architects, highly talented but less original, imitated and developed the architecture formulated by Jones and Wren. The 17th century supplied a mine of architectural motives and enriched England with a few supremely great masterpieces; the 18th century made use of that mine to create a great number of brilliant designs, no one of which quite achieves greatness. (See MODERN ARCHITECTURE: 18th and 19th Centuries.)

There are not lacking in England many examples of the use of Renaissance forms before the 17th century, but the spirit of her architecture remained essentially mediaeval. In the Tudor period, when the cathedral-building impulse had come to an end, when the monasteries ceased to exist and when the building of great country houses had become the chief preoccupation of architects, there grew up a certain simplicity and breadth of handling, a horizontal tendency in composition, which presaged the Renaissance. At the same time the ornamental motives of Italy appeared on the mantelpieces and around the doorways of the Elizabethan houses; and the craftsmen of Flanders, then numerous in England, employed these motives in their decorative work in plaster or carved wood.

Inigo Jones.—The failure of the national style of England to resist the imported Italian style is one of the remarkable

circumstances of Renaissance architecture. Travel in Italy, where the cultivated Englishman might compare the masterpieces of Bramante and Michelangelo with the formless Tudor of his own land, and the importation of Italian books, prepared the way no doubt for the new architecture, but they do not explain its immediate success. That success appears to have been due to the genius and force of one man: Inigo Jones. Jones, almost single-handed, put an end to the mediæval tradition and set up a national movement that rescued English architecture from the Tudor chaos and brought it back to the Roman road along which progress was possible. His supreme accomplishment was to revive in England the conception of architecture as a form-giving art, having an academic and intellectual basis, and to get this accepted as the foundation of a new, national development.

This conception of architecture, rigorously developed by the somewhat intransigent architects of the 18th century, brought into English architecture a certain artificiality which is no doubt the cause of much that is deplorable in the English tradition. A lack of vitality and saliency results when architecture becomes, as it did in Georgian England, a wholly academic art, when the authority of books and of the Italian masters replaces a tradition in building to which the usages of the people, the needs of institutions, the climate and the temper of the nation have contributed. Nor did England develop great sculptors and mural painters to soften, as in France, the austerity of the Roman column and vault. The traditions of fine craftsmanship in plaster and in wood carving remained but they did not suffice to give English Renaissance architecture the warmth, the feeling of having become wholly assimilated, wholly expressive of a national temperament, that one finds in the Renaissance of Italy or Spain.

The reputation of Inigo Jones rests in no small degree on the designs that he made for the great palace at Whitehall in the years 1610-25. This palace is comparable in size to the great projects of the Louvre and the Vatican. The design is splendid and monumental and the palace, had it been erected, would without doubt have been unrivalled, except perhaps by the Escorial, in grandeur of effect. The façades of its seven courts abound in original motives, in which Palladian architecture is skilfully made conformable to English needs. In this, as in all his designs, Jones displays the correctness in proportion and the vigorous and unaffected handling of space and detail, that give his style a nobility and strength exceeding that of any other English architect. The Banqueting hall, which is the only part of the palace of Whitehall actually executed, is an embodiment of these qualities.

Christopher Wren.—On the foundation laid by Jones, Sir Christopher Wren built the great masterpieces of English architecture. To the strength and sensitive feeling for proportion possessed by Jones, he added one of the most active and resourceful imaginations in the history of architecture. To a solid basis of Palladianism—that is to say, to correctness in academic design—Wren added the freedom and movement, the piquancy and drama, of the Baroque. He could unite in one ensemble the two currents into which architecture had divided in the 17th century, the academic and the ingenious, so that they flowed together into a reservoir of original and expressive motives that the 18th century was to find inexhaustible. Very characteristic of this compromise are the 51 parish churches that Wren built in London after the great fire of 1666. Among his secular buildings are important additions to Hampton Court, the library of Trinity college, Cambridge, and the great hospital at Greenwich.

In the city churches Wren created a wholly new type. Built for congregational use, with galleries, shallow chancels and meagre provision for services, they occupy irregular congested sites in the midst of crowded streets. The exteriors had to be severely plain, since funds were scarce; red brick and plaster for the interior were the materials employed. Yet with all these discouragements Wren produced interiors oftentimes full of charm, and exteriors that play a commanding part in their civic environment. These exteriors, plain and even box-like, have slender towers so placed as to be most effective in the street-picture and modelled at the top into delicate spires or lanterns over which there is an encrustation of classic forms.

The secular buildings were more conventional in character. The additions made to Hampton Court (c. 1690) constitute a sober essay in brick-and-stone architecture, somewhat crowded in effect and lacking the repose that marks their Italian prototypes. The Cambridge library (1678) follows the lines of the library at Venice, but is without the piquant proportion and wealth of sculptured ornament that give the Venetian façades so much distinction and grace. Greenwich hospital is more imaginative, having a masterly plan in which four palatial masses are grouped on an axis about two courts. Two domed pavilions are introduced to give the design unity and add life to the façades.

All of these buildings, although exceedingly diverse and original, are of less importance than the great cathedral of London. The ruins of the Gothic cathedral having been cleared away after the Great Fire, Wren was commissioned in 1668 to construct a new St. Paul's in accordance with a Renaissance design that he submitted. During the period from 1675, when the first stone was laid, to 1710, when the work was completed, Wren made many departures from this accepted design, which grew steadily in imaginative power and monumental unity, but at no time did he abandon his central idea, a classic monument contrasted with forms taken from the Baroque. The greatness of St. Paul's is derived, not from the perfection of detail, which is frequently open to criticism, but from the consistency and grandeur with which it realized this idea. The central dome, definite and geometric in mass and in silhouette, imposing in scale, rises from a wide podium and is preceded, at the western end, by two spirited campaniles whose modelled surfaces, profuse shadow and broken silhouette contrast dramatically with the simpler forms with which they are associated.

Eighteenth Century.—After the death of Wren there remained the academic basis which Jones had established for English architecture and the compromise which Wren had brought about between the Palladianism and the virile and free Baroque. These two traditions dominated English architecture and gave direction, in more or less equal degree, to its development during the 18th century. But gradually the academic triumphed. The largeness of conception, the grandiose effect, is forsaken towards the middle of the century in favour of purity and repose.

John Vanbrugh (1664-1726), who did not begin to practice architecture until after the age of 35, was the most robust and daring of Wren's successors and most resembled him in the power and breadth of his imagination. He was the builder of vast country houses, such as Blenheim (1700), 856 ft. long, and Castle Howard (1703), a private dwelling with a dome 100 ft. high. These are monstrous buildings, with innumerable faults of technique and propriety, but magnificent in conception, piling up huge geometric masses around the perimeters of immense courts in a kind of intoxication of architecture.

Nicholas Hawksmoor (1661-1736), a pupil of Wren and an assistant of Vanbrugh, found fewer opportunities than either. For his fine Christ church, Spitalfields, he combined the most original and spirited tower in England with an interior almost unrivalled in formal elegance and classic beauty. The façade that he built for Westminster Abbey is more successful than might have been expected from an age so out of tune with the mediæval spirit. His rugged and simple work contrasts strangely with that of his more successful and versatile contemporary, James Gibbs (1682-1754). Gibbs, like Hawksmoor, a builder of churches in the Wren tradition, shows great facility in adapting and developing motifs taken from Wren; but his care for correct detail and for elegance in technique oftentimes lessens the breadth and virility of his work. The church of St. Mary-le-Strand, in London, is a good example of his style. The Radcliffe library, Oxford, is a more monumental building, but executed with less address. St. Martins-in-the-Fields, London, has a magnificent spire thrust through the roof of a Roman portico; a conception worthy of the greatest Baroque designers, boldly carried out and combined with an interior full of dignity and feeling.

Gibbs was a scholarly architect, possessing that thorough training in Palladian design which is characteristic of the 18th century designers, but he found in Wren a source of vitality which counter-

acted, to some extent at least, the frigidity of the master of Vincenza. Gibbs' contemporaries were often less fortunate: Lord Burlington, a wealthy amateur whose actual accomplishments are still a subject of controversy; Colin Campbell (d. 1734), his protégé and the author of the *Vitruvius Britannicus*; and William Kent (1684-1748), who resided in Burlington House, form a group of academic architects to whom adherence to the Italian model seemed more to be desired than individuality of manner or a continuation of the English tradition of Wren. All were builders of great country houses.

Kedleston Hall, by James Paine (1716-89), recovers to some extent the spirit of Vanbrugh, speaking the language of abstract architectonic form, rather than that of ornament. It is planned in the grand manner, with a porticoed central block flanked by smaller blocks, in which all the parts echo those of the centre. On the major axis are two Roman rooms, one peristyled and one domed. Harewood House, Yorkshire, by Carr of York (1723-80), in which there is, as at Kedleston, a central block flanked by wings, illustrates further the rigid purity of the classic taste of the middle of the century, when the tradition of Wren was disappearing and correct proportion was allowed to take the place of inspiration. The Palladian bridge at Wilton, by Robert Morris, and the house at Prior park, Bath, by John Wood, are other examples.

The last of the Renaissance architects were William Chambers (1726-96) and Robert Adam (1728-92). To the former fell the greatest opportunity of the century, the building of the immense Somerset palace in London. A man of pure taste and of unusual executive powers, he succeeded in creating one of the finest palatial facades in Europe; a façade, however, which has the excellence of scholarship and of technique rather than that of inspiration and power. Adam, who practised in partnership with his brother James, was even more academic in his outlook; his style is, on his exterior designs, simple, tenuous and dry in the extreme. His interiors, which often take unusual shapes in plan and in the modelling of ceilings, are enriched by a delicate and graceful system of decoration which, when skillfully executed, attains a unique loveliness. His influence was enormous and under his leadership the architecture of the Renaissance came to an end.

RENAISSANCE ART. The revival of classic learning in Italy, which was so marked a feature of Italian culture during the 15th century, was paralleled by an equal passion for the beauty of classic design in all the artistic fields; and when this eager delight in the then fresh and sensuous graciousness that is the mark of much classic work—to the Italians of that time, seemingly the expression of a golden age—became universal, complete domination of the classic ideal in art was inevitable.

This turning to classic models was less sudden and revolutionary than it seemed. Throughout the history of Romanesque and Gothic Italian art, the tradition of classic structure and ornament still remained alive; again and again, in the 12th and 13th centuries classic forms—the acanthus leaf, moulding ornaments, the treatment of drapery in a relief—are imitated, often with crudeness, to be sure, but with a basic sympathy for the old imperial Roman methods of design. (See **GOthic ART**; **ROMANESQUE ART**.) How much more at home seems the mediaeval Italian artist, who carved the spiralling acanthus leaves on the doors of Pisa cathedral (11th century) than the designer of the laboured and stupid, crocketed capitals of the cathedral in Florence (14th century), or the contorted and unconvincing buttress pinnacles of Milan cathedral (begun 1386). The best of Italian Gothic art is always that which is least like northern Gothic, and is usually dominated by ideals, essentially those of earlier Italian building, like the Byzantine palaces of Venice. Niccolò Pisano (c. 1206-1280) was but the first of many Italian

artists, particularly sculptors, to turn definitely to Roman sculpture for inspiration.

It was therefore only natural that Brunelleschi (1377-1476) should study the ruins of ancient Rome, and that, following his example, the whole artistic world of Florence turned to the same source of inspiration almost unanimously. Brunelleschi's famous cupola over the cathedral of Florence completes the work of the preceding age and is not yet a Renaissance manifestation. The new style was displayed in the Pazzi chapel and in the plans for San Lorenzo and San Spirito.

Florence was the great centre of this early Renaissance; whence it spread throughout Italy in the 15th century; the greater number of artists were Florence-trained. The enthusiastic patronage of art of the new type by Cosimo dei Medici (1389-1464), and Lorenzo dei Medici (1449-1492), who founded the famous Platonic Academy, gave a tremendous impetus to the movement, and the general Florentine method of art training, through *botteghe*, or craftsman shops, assured the fact that the Renaissance was not confined to architecture and sculpture, but spread to all the industrial arts as well.

Another element besides the influence of ancient Rome becomes evident as the Renaissance matured in such of the minor arts as textiles, pottery and metal work. This was the influence of the Near East. Commerce between Italy and the Turkish dominions was constant and large in amount, and Oriental pottery and textiles were much sought after. When the Italians started manufacturing their own goods to compete with this foreign source, imitation and adaptation of the Oriental patterns was natural. Thus the controlling designs of Venetian velvets and brocades, down to the 18th century, owe much to the carnation and the palmette of Persia, and in 16th and 17th century armour and silver-ware, there occur the spear-head shapes and bifurcated leaves and intricate interlaces of fine lines which characterize the inlaid brass, copper and steel of Damascus or Constantinople.

By the beginning of the 16th century the tentative and experimental characteristics of the earlier Renaissance had, in Italy, given way to the mature, knowing, and facile use of classic forms which constitutes the High Renaissance or cinquecento (q.v.). In architecture, the orders were used with entire command; in the minor arts the decorative exuberance of the 15th century was yielding to sounder and more dignified conceptions. Yet the development of this polished classicism was limited and eager; creative imaginations refused to be bound by it. The result was the resurgence of untrammelled and, at times, unlicensed individualism in design, which is known as the Baroque or late Renaissance. Already, in the work of Michelangelo, 1474-1564, and Cellini, 1500-71 (see **SILVERSMITHS' AND GOLDSMITHS' WORK**), Baroque elements are obvious, and by the year 1600 the ideals of climax, broken curves, magnificent composition and dynamic contrasts, which constitute the Baroque movement, were universally accepted, and the classic forms became merely an inspirational frame-work for individual development and creation. The Baroque was a style curiously turgid, often gigantesque, theatrical, often denying or falsifying structural framework, yet magnificently alive; producing alike such over lavish and ill considered decorations as those of Andrea Pozzo (1642-1709) for the church of S. Ignazio in Rome and the dignified and monumental colonnades of the Piazza of S. Peter's, by Bernini (1598-1680). During the 18th century the vitality of the Baroque degenerated into a chaos of contorted forms, to be in turn replaced, at the end of the century, by a recrudescence of stern, cold and rather sterile classicism. Yet the Renaissance in Spain was no mere copy of the Italian.

Renaissance feeling was introduced into Spain during the latter years of the 15th century by wandering Italian sculptors, but a school of native artists soon developed, and during the 16th century an individual school of Renaissance dominance was complete, despite the Italian impetus given by the campaign of Charles V., 1500-58, and the fanatical Romanism of his son Philip II., 1527-598, whose palace monastery, the Escorial, by Juan Bautista (16th century) and Juan de Herrera (1530-97), is a stark and lonely monument to Philip II.'s Italian taste. Else-

where, the Moorish influence was so strong as to modify the Italian forms profoundly; Moorish craftsmen controlled the potteries and often built the buildings. Moreover, perhaps due to the bleak and sombre character of so large a part of the Spanish territory, the emotional quality of the Spanish Renaissance work has a sharp pungency quite different from the usual graciousness of the Italian feeling. The style in Spain may be divided into three parts—the early Renaissance, or Plateresque (q.v.), in which Moorish influence is marked; the classic or Griego-Romano, a short and sterile attempt to introduce strict Italian classicism; and the Baroque or Churrigueresque, so-called from one of its main exponents, Jose Churriguera (died 1725). It was in this final style that the Spanish temperament found itself most at home. Particularly characteristic of the Spanish Renaissance is the work in certain of the minor arts, especially in iron work, as shown in the magnificent church screens, or rejería (q.v.); in furniture, in which iron and wood were frequently combined; and in stamped leather, for which Spain was famous.

In France, the history of the early Renaissance shows a style originally essentially an imported court fashion, gradually permeating all French life. The Italian campaigns of Charles VIII, 1490-1498, Louis XII, 1462-1515, and Francis I, 1494-1547, had given the French court an intimate knowledge of the comparative luxury, cleanliness and monumentality of the Italian cities. Italian artists were invited to the court; Italian decorators and architects helped Francis I in his great building schemes. Yet this court fashion had to compete with a vivid and vital flamboyant, late Gothic style, and much of the charm of the early French Renaissance results from the naive, yet brilliantly executed combinations of the two influences. During the reign of Henry II, 1547-1559, the classic ideal was dominant, though Gothic forms were still in use. Under Henry IV, 1553-1610, though the Gothic had at last passed away, Baroque freedom controlled design, and under Louis XIII, Louis XIV, Louis XV and Louis XVI whose reigns stretched from 1610 to 1793, there was a continual see-saw between academic classicism and imaginative freedom. (See LOUIS STYLES.)

From the beginning a court style, the French Renaissance remained essentially a luxurious one. All of the arts of luxury flourished. Rich textiles—tapestries and brocades—were characteristic, and the lavish furniture was copied all over Europe, especially during the 18th century. The development of pottery, first privately, and later under government auspices, culminated in the magnificent porcelains of Sévres.

The development of the Renaissance in the rest of Europe was marked by common features. In England and the Teutonic countries, there was not only a late vital Gothic style, but definite characteristics of national taste and vastly different climatic and geographical conditions. Yet the humanistic impetus of the Renaissance existed almost everywhere and the beauty of the naturalistic painting and sculpture, as well as the exquisite productions of Italian goldsmiths, formed a continual invitation toward a change in artistic ideals. Thus, despite occasional purely classic work by Italian artists, such as Torregio's tomb of Henry VII in Westminster abbey, London (1515), the early Renaissance in north Europe is chiefly characterized by the gradual creeping in of misunderstood classic decorative forms, often caricatured. In none of these countries did classicism become dominant until the 17th century, and even then it is coloured by local taste. Thus in Germany, the picturesqueness of late Gothic decorative design controlled all of the arts down to the 18th century and even the pseudoclassic of the French inspired Rococo embodied many picturesque elements. In England, due to the influence of Inigo Jones, 1572-1652, and Sir Christopher Wren, 1632-1723, at least in architecture, classic forms were used with purity and unusual correctness. In Germany and Flanders, on the other hand, Baroque elements were favoured, especially in woodcarving and the minor arts generally; and through the diffusion of Flemish craftsmen consequent upon the confused religious and political conditions during the 17th century, these northern varieties of Baroque forms were broadcast over Europe, influencing markedly the later Renaissance work

in England and recognizably, though to a less extent, that of France and Spain. This confusion of international influences marked the Renaissance of the 18th century, the style movements in France being generally paralleled by those in other countries. Yet the erratic swing between licence and classicism was indicative of a decaying style vitality, and new archaeological discoveries were giving to the classicism of the end of the century a motivation quite different from the simpler Renaissance tradition that was dying. With the fall of the French court, in the French revolution, more than a political system was swept away, for with it went the last vestiges of Renaissance tradition. See BAROQUE ARCHITECTURE; BRONZE AND BRASS ORNAMENTAL WORK; INTERIOR DECORATION; PAINTING; POTTERY AND PORCELAIN; RENAISSANCE ARCHITECTURE; ROCCO; LOUIS STYLES; RUGS AND CARPETS; SILVERSMITHS' AND GOLDSMITHS' WORK; TAPESTRY.

(T. F. H.)

RENAIX (Flem. *Ronse*), town, province of East Flanders, Belgium, 8 mi. S. of Oudenarde, at the foot of the hills of Flanders. It has yielded many pre-Roman and Roman finds. There are manufactories for woollen and linen goods. Pop. (1939) 25,491.

RENAN, ERNEST (1823-1892), French philosopher and orientalist, was born on Feb. 27, 1823, at Tréguier. His father's people were of the fisher-clan of Renans or Ronans. He was only 5 years old when his father died, and his sister Henriette, 12 years older than Ernest, a girl of remarkable character, was henceforth morally the head of the household. Ernest was educated in the ecclesiastical college at Tréguier. In the summer of 1838 he carried off all the prizes at the college. Through his sister, who was teaching in Paris, Felix Dupanloup heard of him, and sent for him at once, and placed him in the new ecclesiastical college of St. Nicolas du Chardonnet. He then proceeded to study for the priesthood at the Seminary of Issy, then at St. Sulpice, and finally he found his way to Stavistas, a lay college of the Oratorians. He soon found himself torn between his desire to lead the life of a Catholic priest and his intellectual inability to accept in its entirety the ordinary presentation of Catholic doctrine, or to submit to ecclesiastical authority. Even at Stavistas he found himself too much under the domination of the church, and, after a few weeks there, he reluctantly broke the last tie which bound him to the religious life, and entered M. Crouzet's school for boys as an usher. There he made the acquaintance, in 1846, of the chemist Marcellin Berthelot, then a boy of 18. To the day of Renan's death their friendship continued. Renan was occupied as usher only in the evenings. In the daytime he continued his researches in Semitic philology. In 1847 he obtained the Prix Volney for his *General History of Semitic Languages*.

The revolution of 1848 confronted him with the problems of democracy. The result was an immense volume, *The Future of Science*, which remained in manuscript until 1890. *L'Avenir de la science* is an attempt to conciliate the privileges of a necessary élite with the diffusion of the greatest good of the greatest number. In 1849 the French government sent him to Italy on a scientific mission. In Italy the artist in him awoke and triumphed over the savant and the reformer. On his return to Paris Renan lived with his sister Henriette. A small post at the National library, together with his sister's savings, furnished him with the means of livelihood. In the evenings he wrote for the *Revue des deux mondes* and the *Débats* the exquisite essays which appeared in 1857 and 1859 under the titles *Études d'histoire religieuse* and *Essais de morale et de critique*. In 1852 his book on *Averroës* had brought him not only his doctor's degree, but his first reputation as a thinker. In his two volumes of essays Renan shows himself a liberal, but no longer a democrat. Nothing, according to his philosophy, is less important than prosperity. The greatest good of the greatest number is a theory as dangerous as it is illusory. Man is not born to be prosperous, but to realize, in a little vanguard of chosen spirits, an ideal superior to the ideal of yesterday. Only the few can attain a complete development. Yet there is a solidarity between the chosen few and the masses which produce them; each has a duty to the other. The acceptance of this duty is the only foundation for a moral and just society. The aristocratic idea has seldom been better stated.

DECORATIVE DETAILS OF THE RENAISSANCE

1. "The oration of Adam and Eve and their expulsion from Paradise," a panel in bronze by Lorenzo Ghiberti (1378-1455) in the famous east door made for the Baptistery in Florence between 1425 and 1452, a masterwork of early Renaissance decorative sculpture
2. Vault of the Scala d'Oro in the Doges' Palace, Venice, designed by Jacopo Sansovino (1486-1570)
3. Glazed polychrome terra cotta, "Assumption of the Virgin" by Luca della Robbia (1400-82), characteristic of the early Florentine Renaissance in its perfect blend of architecture and sculpture as well as in the exquisite delicacy of its modelling. In the Metropolitan Museum of Art, New York
4. Swiss room, 17th century, the woodwork characteristic in its free handling of Baroque motives. Now in the Berne Museum
5. Swiss paneled room, 17th century, with rich Baroque woodwork and a magnificent porcelain stove. Now in the Metropolitan Museum of Art, New York
6. The seat for the Archbishop of Canterbury incorporated in the choir stalls of St. Paul's cathedral, London, executed by the wood carver Grinling Gibbons (1648-1720) in collaboration with the architect Sir Christopher Wren (1632-1723). It is characteristic in its dignified combination of restrained Baroque forms with figures, heads and naturalistic foliage

APPLIED ARTS OF THE RENAISSANCE

1. Halberds: left, German, 16th century, characteristic in its fine decoration on the surface of the metal; right, Italian, 16th century, showing greater amount of modelling in the round and strong Baroque elements. 2. Louis XIV. tapestry, French, of the last half of the 17th century, showing the return of the Sabine women with the Roman soldiers; probably one of a set woven at the royal looms of the Gobelins. 3. Embroidered Italian altar frontal, with touches of naturalistic ornament, in the manner of Louis XIII, and early Louis XIV. textiles. 4. A three-quarter suit of Italian armour,

clothed and gilded, and showing the arms of the Barberini family, probably once the property of Teddeo Barberini, middle 17th century. It illustrates the lavishness of ornament applied to arms and armour in the Baroque period. 5. French Renaissance helmet; on the left, period of Henry II., with typically fantastic outline. 6. French silk brocade of about 1700, showing a characteristic Louis XIV. mixture of Baroque line and naturalistic detail. 7. A dagger and scabbard, dated 1567, of Swiss manufacture

Renan now began to frequent more than one Parisian salon, and especially the studio of Ary Scheffer, whose niece and adopted daughter, Cornélie, he proposed to marry in 1856. Henriette consented not only to the marriage, but to make her home with the young couple, whose housekeeping depended on the sum that she could contribute. The history has been told by Renan in the memorial essay, *Ma Soeur Henriette*. In 1859 appeared his translation of the *Book of Job* with an introductory essay, followed in 1859 by the *Song of Songs*.

Renan was now a candidate for the chair of Hebrew and Chaldaic languages at the Collège de France. The Catholic party, upheld by the empress, would not appoint an unfrocked seminarian, a notorious heretic, to a chair of Biblical exegesis. Yet the emperor wished to conciliate Ernest Renan. He offered to send him on an archaeological mission to Phœnicia. Leaving his wife at home with their baby son, Renan left France, accompanied by his sister, in the summer of 1860. Madame Renan joined them in January 1861, returning to France in July. The mission proved fruitful in Phœnician inscriptions which Renan published in his *Mission de Phénicie*. They form the base of his *Corpus Inscriptionum Semiticarum*. At Amshit, near Byblos, Henriette Renan died of intermittent fever on Sept. 24, 1861. Her brother, himself at death's door, was carried unconscious on board a ship waiting in harbour and bound for France. On Jan. 11, 1862, the Minister of Public Instruction ratified Renan's election to the chair of Hebrew. But his opening lecture, in which, amid the applause of the students, Renan declared Jesus Christ "an incomparable Man," alarmed the Catholic party. Renan's lectures were pronounced a disturbance of the public peace, and he was suspended. He refused the librarian's post he was offered in exchange, and thenceforth lived by his pen.

Vie de Jésus.—Henriette had told him to write the life of Jesus. They had begun it together in Syria, she copying the pages as he wrote them, with a New Testament and a *Josephus* for all his library. The book is filled with the atmosphere of the East. It is the work of a man familiar with the Bible and theology, and no less acquainted with the inscriptions, monuments, types, and landscapes of Syria. But it is scarcely the work of a great scholar. Renan still used his literary gifts to pursue a scientific ideal. He produced the *Apostles* in 1866, and *St. Paul* in 1869, after having visited Asia Minor with his wife. His object was "to evoke from the past the origins of Christianity." In *St. Paul*, as in the *Apostles*, Renan shows his concern with the larger social life, his sense of fraternity, and a revival of the democratic sentiment which had inspired *L'Avenir de la science*.

The Franco-German War was a turning-point in Renan's history. Germany had always been to him the asylum of thought and disinterested science. Now his heart turned to France. In *La Réforme intellectuelle et morale* (1871) he endeavoured at least to bind her wounds, to safeguard her future. At the same time the irony always perceptible in his work grows more bitter. His *Dialogues philosophiques*, written in 1871, his *Ecclesiastes* (1882) and his *Antichrist* (1876) (the fourth volume of the *Origins of Christianity*, dealing with the reign of Nero) show a disenchanted and sceptical temper. Gradually he aroused himself from his disillusioned mood, and observed with genuine interest the struggle for justice and liberty of a democratic society. The fifth and sixth volumes of the *Origins of Christianity* (the *Christian Church* and *Marcus Aurelius*) show him reconciled with democracy, confident in the gradual ascent of man.

Later Works and Death.—In 1883 he published *Souvenirs d'enfance et de jeunesse*, which have the Celtic magic of ancient romance and the simplicity, naturalness and veracity prized in the 19th century. But his *Ecclesiastes*, published a few months earlier, his *Dramas philosophiques*, collected in 1888, give a more adequate image of his fastidious, critical, disenchanted, yet not unhelpful spirit. They show the attitude towards uncultured Socialism of a philosopher liberal by conviction, by temperament an aristocrat. We learn in them how Caliban (democracy), the mindless brute, educated to his own responsibility, makes after all an adequate ruler; how Prospero (the aristocratic principle, or, if we will, the mind) accepts his dethronement for the sake of

greater liberty in the intellectual world, since Caliban proves an effective policeman, and leaves his superiors a free hand in the laboratory; how Ariel (the religious principle) acquires a firmer hold on life, and no longer gives up the ghost at the faintest hint of change. Religion and knowledge are as imperishable as the world they dignify. Thus out of the depths rises unvanquished the essential idealism of Ernest Renan.

At sixty years of age, having finished the *Origins of Christianity*, Renan began his *History of Israel* (3 vols., 1887-91) based on a lifelong study of the Old Testament and on the *Corpus Inscriptionum Semiticarum*, published by the Académie des Inscriptions under his direction from the year 1881 till the end of his life. He died on Oct. 12, 1892.

There is no collected edition of Renan's works. There is an English translation of the *Vie de Jésus* in Everyman's Library (1927). His *Correspondance* has been edited in 4 vols. (Paris, 1910-28). For Henriette Renan see Prof. Giraud, *Soeurs de grands hommes* (1926) and Renan's *Lettres Intimes* (1923).

RENARD, ALPHONSE FRANÇOIS (1842-1903), Belgian geologist, was born at Renaix on Sept. 27, 1842.

His first work (with Charles de la Vallée-Poussin, 1827-1904), was the *Mémoire sur les caractères minéralogiques et stratigraphiques des roches dites pléistocènes de la Belgique et de l'Ardenne française* (1876). In later essays and papers he dealt with the structure and mineral composition of many igneous and sedimentary rocks, and with the phenomena of metamorphism in Belgium and other countries. Still more important were his later researches connected with the Challenger Expedition. The various rock specimens and oceanic deposits were submitted to him for examination in association with Sir John Murray, and their detailed observations were embodied in the *Report on the Scientific Results of the Voyage of H.M.S. "Challenger" Deep Sea Deposits* (1897). The more striking additions to our knowledge included "the detection and description of cosmic dust, which as fine rain slowly accumulates on the ocean floor; the development of zeolitic crystals on the sea-bottom at temperatures of 32° and under; and the distribution and mode of occurrence of manganiferous concretions and of phosphatic and glauconitic deposits on the bed of the ocean" (Geikie). Renard was professor at the Jesuit College of Louvain and then at the University of Ghent. He died at Brussels on July 9, 1903.

Obituary by Sir A. Geikie in *Quart. Journ. Geol. Soc.*, li. 1904.

RENARD THE FOX: see REYNARD THE FOX.

RENAUD DE MONTAUBAN (Rinaldo di Montalbano), one of the most famous figures of French and Italian romance. His story was attached to the *geste* of Doon of Mayence by the 13th-century trouvère who wrote the *chanson de geste* of Renaud de Montauban, better known perhaps as *Les quatre fils Aymon*. The four sons of Aymon give their name to inns and streets in nearly every town of France, and Renaud's sword Floberge, and his horse Bayard passed with him into popular legend. The poem opens with the dissensions between Charlemagne and the sons of Doon of Mayence, Beuves d'Aigremont, Doon de Nanteuil and Aymon de Dordone. The rebellious vassals are defeated by the imperial army near Troyes, and, peace established, Aymon rises in favour at court, and supports the emperor, even in his persecution of his four sons, Renaud, Alard, Guichard and Richard. At the end of the usual series of violent adventures and catastrophes, Renaud gives himself up to religion, working as a mason on the church of St. Peter at Cologne, where he receives martyrdom at the hands of his jealous fellow-labourers.

The connection of the four brothers with Montessor, Dortmund, Mayence and Cologne, and the abundant local tradition, mark the heroes as originating from the region between the Rhine and the Meuse. Nevertheless, their adventures in Gascony, with the king of which they take service against the Saracens, are

corroborated by historical evidence, and this section of the poem is the oldest. The enemy of Renaud was Charles Martel, not Charlemagne; King Yon was Odo of Gascony; the victory over the Saracens at Toulouse, in which the brothers are alleged to have taken part, was won by him in 721, and in 719 he sheltered refugees from the dominions of Charles Martel, Chilperic II, king of Neustria, and his mayor of the palace, Raginfrid, whom he was compelled to abandon. In a local chronicle of Cologne it is stated that St. Reinoldus died in 697, and in the Latin rhythmic *Vita* his martyrdom is said to have taken place under Bishop Agilolf (d. 717). Thus the romance was evidently composite before it took its place in the Carolingian cycle.

In Italy Renaud had his greatest vogue, and many episodes were added, as well as the personage of the hero's sister, Bradamante. Rinaldo di Montalbano had been the subject of many Italian poems before *Il Rinaldo* of Tasso.

BIBLIOGRAPHY.—*The chanson of Margis d'Aigremont and the prose romance of the Conquests de Trebisonde* belong to the same cycle. The prose *Ystoria de Regnau de Montauban* (Lyons, c. 1480) had a great vogue. It was generally printed as *Les quatre fils Aymon*, and was published in English, *The Four Sonnes of Aymon*, by William Caxton, and subsequently by Wynkyn de Worde and William Copland. See *Hitt. litt. de la France*, xxi., analysis by Paulin Paris; *Renaud de Montauban* (Stuttgart, 1862), ed. H. Michelant; *Storia di Rinaldo*, ed. C. Minutoli (Bologna, 1862); F. Wolff, *Recherches sur les sagas de Margis et de Gérard* (Lund, 1873); *Renaud von Montalbano*, ed. J. C. Matthies (Groningen, 1873); *Magus saga*, ed. G. Cederschiöld (Lund, 1876); A. Longnon, in *Revue des questions historiques* (1879); R. Zwich, *Über die Sprache des Renaud von Montauban* (Halle, 1884); *The Four Sonnes of Aymon* (E. E. Text Soc., ed. Octavia Richardson, 1884); F. Pfaff, *Das deutsche Volksbuch von den Reymonskindern* (Freiburg in Breisgau, 1887), with a general introduction to the study of the saga; a special bibliography of the printed editions of the prose romance in L. Gautier's *Bibl. des chansons de geste* (1897); rejuvenations of the story by Karl Simrock (Frankfurt, 1845), and by Richard Steele (1897).

RENAUDOT, THÉOPHRASTE (1586–1653), French physician and philanthropist, was born at Loudun (Vienne), and studied surgery in Paris. He was only nineteen when he received, by favour apparently, the degree of doctor at Montpellier. After some time spent in travel he began to practise in his native town. In 1612 he was summoned to Paris by Richelieu, received the titles of physician and councillor to the king, and was desired to organize a scheme of public assistance. Many difficulties were put in his way, however, and he returned until 1624 to Poitou, where Richelieu made him "commissary general of the poor." But in 1630 he opened an information bureau in Paris at the sign of the Grand Coq near the Pont Saint-Michel. This bureau *d'adresse* was labour bureau, intelligence department, exchange and charity organization in one; and the sick were directed to doctors prepared to give them free treatment. Presently he established a free dispensary in the teeth of the opposition of the faculty in Paris. The Paris faculty refused to accept the new medicaments proposed by the heretic from Montpellier, restricting themselves to the old prescriptions of blood-letting and purgation. Under the protection of Richelieu Renaudot started the first French newspaper, the *Gazette* (1631), which appeared weekly; he also edited the *Mercurius francicus*. In 1637 he opened in Paris the first Mont de Piété, an institution of which he had seen the advantages in Italy. In 1640 the medical faculty, headed by Guy Patin, started a campaign against the innovator of the Grand Coq. After the death of Richelieu and of Louis XIII. the parliament of Paris ordered him to return the letters patent for the establishment of his bureau and his Mont de Piété, and refused to allow him to practise medicine in Paris. The *Gazette* remained, and in 1646 Renaudot was appointed by Mazarin historiographer to the king. He died on Oct. 25, 1653.

See E. Hatin, *Théophraste Renaudot* (Poitiers, 1883), and *La Maison du Coq* (Paris, 1885); Michel Emery, *Renaudot et l'introduction de la médecine chimique* (Paris, 1889); and G. Bonnefont, *Un Oublié, Théophraste Renaudot* (Limooges, n.d.).

RENDERING, ARCHITECTURAL. Architectural rendering is a pictorial art whose object is to visualize architectural conceptions. When an architect is employed to design a building, it is desirable that he provide his client, in advance, with an accurate

impression of the appearance of the proposed structure. Since words cannot adequately convey the architectural story, paintings or drawings are employed to render it, as it were, clear to the eye; they serve as a kind of communication. This is the most familiar application of the art; and, when so used, rendering may be defined as the medium whereby the renderer communicates a sense of the reality of a structure in advance of its concrete materialization. Occasionally, however, the architect has a rendering made in the course of his own work and as an aid to his own study. When an architectural conception first forms in the background of his mind, it has, of necessity, a certain nebulous character. But with the effort of expressing it on paper, in actual lines and tone values, it emerges, so to speak, and crystallizes. When so employed, rendering serves as a definite step in the evolution of architectural conceptions.

Rendering has a third use; viz., in connection with already existing buildings. When so used, renderings—as distinguished from the miscellaneous paintings and drawings that refer only incidentally to architecture—have, as their chief or sole concern, to render clear the strictly architectural nature of the subject. By this selection of architectural factors, they may enable the layman to grasp the significance of a building more readily than when faced by its multitudinous and irrelevant details. At the same time, they may serve as a faithful record of the historic course of architectural design. In these three ways, rendering fulfills a recognized function, and has done so over a long period.

In the last quarter of a century, there has developed an aspect of architectural and engineering practice that involves rendering on a more extended scale—town and city planning (*q.v.*). A comprehensive plan for the future building development of any large community is never the conception of a single mind; many minds must collaborate in it. Nor is it materialized in a few years, but in many years. In these circumstances, it becomes impractical for its whole purport to be carried only in any single given mind, or for an accurate image to be postponed until the whole long scheme has been consummated. The various contributory ideas and suggestions must be assembled, in definitive terms, on the paper or canvas of the rendering, in order that the prophecy may assume sufficient reality to serve as a criterion and a guide.

Another factor, which more clearly reveals the contemporary field of rendering, is that Western architecture, as a whole, is passing through a period of transition and, therefore, of experiment (*see ARCHITECTURE*). It is true that the practice of many of the most prominent architects is to continue constructing mere copies, or very slightly modified copies, of those classic styles which, in their impressionable years, they were led to regard as being the very body of architectural culture; their effort is to emulate the classic designers in all respects, save, perhaps, the latter's logic, sense of congruity and ability to fashion novel forms. Their public, accordingly, has been wont to feel the presence of architecture only in a building to which the architect has added a Greek colonnade, a Roman dome or a Gothic spire. In all this, professional rendering has been able to play but a small part, since the picture has been regarded as an end in itself simply to be made as attractive as possible; it could scarcely be employed as a means of rendering forth a new truth, more especially as the appearance of these styles of architecture has been known for centuries.

In recent years, however, definite changes have occurred in methods of construction and the manufacture of materials, as well as in the general social and economic situation; and one notices that in the larger centres of Western civilization a distinct type of designer is making his presence in the architectural profession more and more strongly felt. These designers are inspired not so much by the traits of an architectural heredity as by the needs of contemporary environment. For them, the tremendous environmental changes that have occurred imply and demand a corresponding change in the architectural approach. They do not—to choose one example—employ a new material, steel, to support façades, which have developed in other materials and can be logical only therein. They are engaged, briefly, in developing new types of architecture. Certain limitations lie upon these practising

BY COURTESY OF (2) HOLABIRD AND ROGIE, ARCHITECTS

EXAMPLES OF VARIOUS TYPES OF RENDERINGS

1. Carbon pencil drawing on cumeo paper: made to visualize a proposed structure; effect of mass remaining dominant in spite of thoughtful delineation of detail; sense of relation to surroundings. By Chester B. Price. 2. Crayon drawing: made to visualize proposed structure; arbitrary handling of tone values, details and envelope resulting in an unusual impression of mass. By Gilbert P. Hall. 3. Wash: made to visualize a proposed structure; grasp of architectural factors, sensitive feeling, conveyed through a cultured technique. By H. VanBuren Magonigle.

RENDERING, ARCHITECTURAL

Jan. 1896

RENDERINGS IN VARIOUS MEDIUMS

1. Engraving: structural factors, accurately sensed, recombined with a child's imagination, conveying powerful emotional impression. By Piranesi.
 2. Pencil drawing, coffee wash: made to visualize a design project; primarily concerned with the architectural conception, yet adequate attention given to pictorial values. By Eino Saarinen.
 3. Etching: Imaginary composition on historical motif; highly stimulating impressions. By William Welton.

4. Pastel: selection of architectural factors from an existing building; thoughtful composition of subject matter, affectionate attention to technique. By T. de Postels.
 5. Pencil: example of a one minute sketch made to convey an architect's conception to his assistants; attention centred on essentials of the design (which were later constructed as sketched). By Cass Gilbert

and experimental architects. It is sometimes too hazardous to test a novel conception by actually carrying it out in a building which, whether a success or a failure, must stand for many years. But the conception may be quite thoroughly tested in a series of conscientious renderings. For example, the modern American zoning laws involved a radical departure in the general forms of buildings, and into the strange spaces created by these laws some architects proceeded without pause to force the classical images with which their minds were filled. More cautious architects sought to discover the basic structural types that the laws admitted; for this purpose, renderings were employed. Another limitation is that the projects of architects are practically bound by the ideas and the financial resources of their clients; they cannot actually build in advance of their clients' prepossessions. In renderings, however, they may freely express their real intentions, and these renderings, when duly exhibited can, and in fact do, make a distinct contribution to the progress of architectural design. A third limitation is that no practising architect, however fortunate, has time to build more than a very few influential buildings during his lifetime. He may, however, record himself in soundly fashioned drawings and paintings whose content, though at first existing in only two dimensions, may, in due time, be realized in three.

In addition to the functions thus far mentioned, rendering has a rôle to play in what is doubtless the greatest concern of architecture—the psychological influence it exerts on human life. A few people, it is true, are fully conscious of the impressions that they receive in the face of noble buildings; the more pertinent and important fact is that the vast majority of human beings are continually, if unconsciously, influenced by the architectural forms and spaces with which they come in contact. Architects themselves are often unaware of the extent of this influence; that is to say, the influence which is unconsciously received is unconsciously initiated. Perhaps it is in consequence of this that the haphazard and miscellaneous architectural scene which is presented by most modern cities, and which is constantly before the population, is left to impress the corresponding qualities upon the human psyche. On the other hand, there have been periods in the past—the "great periods" of architecture—when the designers must have been quite aware of the influence, and utilized it for conscious purposes. In the Gothic cathedrals, for example, there is embodied, in terms of form and space (terms safely beyond the vicissitudes of any particular church) a potent and lasting influence for the betterment of mankind. Buildings of the first category—depressing or distracting buildings—are legion; those of the second—buildings which arrest or elevate—are rare. But the more significant forms may be repeatedly delineated and interpreted in drawings and paintings by whose agency they may be widely exhibited, published and, so to speak, broadcast. Rendering, in short, by allying itself with the conscious and objective forces in architectural work, may serve, by paraphrase, to bring home the laconic message of architecture.

To sum up, rendering has six principal objects. The first three have long been recognized: to convey advance realizations of proposed structures, to aid in crystallizing ideas in the architect's mind and to interpret the architectural significance of existing structures. The other three remain largely for future development: to serve as criterion and guide in city planning, to assist in evolving new types of architecture and to strengthen the psychological influence of architecture on human values.

Whichever of these objects a given rendering is to serve, the renderer—having comprehended *why* the drawing is being made—is faced with two fundamental considerations. The first is to grasp *what* is the nature of the architectural subject to be rendered, to so ponder it as to exclude non-essentials. The second is *how* to employ the various devices of draughtsmanship so as to communicate this realization to others. Between these two items—the nature of the subject and the process of rendering—there exists the distinction between ends and means, and it is important that the renderer have this distinction clearly in mind at the outset.

As a matter of common practice, this distinction is often not made. The painting or drawing is often regarded as being an end

in itself, and discussion of it centres, in consequence, on purely technical questions: interest of composition, nicety of line, cleverness of brushwork, etc. Many such works are contributions to the subject of technique and justify the enthusiasm of technicians; but, lacking architectural significance, they are not, strictly speaking, architectural renderings.

It is also a common practice to regard rendering as indeed a means but to substitute for its authentic and natural ends, ends that are special or perverted. For example,—as in the *Beaux Arts* curriculum—projects are often rendered in elevation (*i.e.*, the representation is of but one façade of the building as this would appear were the eye directly opposite each and every point thereon). This, obviously, produces a form which can exist only on paper; it is not the form which the human eye would perceive in the building itself. Such a treatment serves a purpose, in that an architect, when reading its conventionalized and inexact statement, can translate it, in his trained mind, into at least an approximation of the truth. But just because it requires a translation, and is, in itself, foreign to reality, it may be classified as a special practice.

Another common practice, of a different category, is to accomplish, by means of a picture, an end which is positively opposed to architectural fact. The renderer may be called on to exaggerate certain aspects of a proposed building in order to create a more favourable advance impression; or to exaggerate certain factors of an existing building in a way to advertise them. The architect or advertiser may wish such a rendering as a result of deliberate calculation or because his personal interest in particulars is so great as to obscure from his view the real appearance of the building in its entirety. In any case, the executing of such commissions falls rather into the class of commercialized art and may be excluded from a discussion on rendering.

The twofold criterion of values remains to be applied to all renderings: first, comprehension of the architectural essentials involved in the subject; second, effectiveness in pictorial communication.

ESSENTIALS TO BE RENDERED

Mass.—From the renderer's point of view a building is, in the first place, a material mass. While it is not, in actuality, a mass in the sense that a mountain is a mass, *i.e.*, it is not a solid, nevertheless the effect of solidity is essential to it. And while, in constructing a building, this effect may be the last to be realized, in drawing a building it is logically the first. The renderer must realize the presence of mass before he can fully realize the presence of any appurtenant form. It may be likened to the clay which a sculptor must grasp before any particular shape can be given or any details modelled. The first necessary attribute of a convincing architectural rendering is, correspondingly, an adequate suggestion of mass. Without this primary effect of solidity, all details which may be delineated later must appear without body and the presentation as a whole must lack substance.

Form.—Being imbued with a sense of the substantial nature that his subject, in general, possesses, the renderer addresses himself to a study of its particular form. It is generally taken for granted that if accurate floor plans and elevations are available, an accurate image of the building can be produced by following the rules of perspective draughtsmanship—those rules are said to have originated with Leonardo and are commonly accepted as being correct and comprehensive. The fact is, however, that there is considerable question as to how forms really look. It is quite doubtful if the system of perspective draughtsmanship which we accept as a science, is more than a convention—a convention which, indeed, is usually of great help to accurate representation and yet, in numerous instances, is a specific hindrance. The forming, in the human eye of images of buildings appears, in fact, to involve factors with which we, as renderers, have not yet adequately dealt (*see PERSPECTIVE*).

The Single Viewpoint.—One item to be considered in this connection is that, in laying out perspectives the draughtsman habitually assumes that the subject is being viewed from a single viewpoint. He establishes, on his draughting board, a specific

point, termed the "viewpoint" and his operations proceed from this base. But this assumption is inadequate to the extent that the appearance which a building actually produces on a one-eyed man is inadequate as compared to that produced on a two-eyed man. In some cases, the discrepancy is not remarkable—as, for example, small forms viewed at considerable distances. But, in forms which are closely scrutinized, the discrepancy becomes pronounced; there is a definite lack of the three-dimensional quality to the single-eyed vision, and there is a corresponding flatness to the general run of perspectives laid out from the single viewpoint.

The Stationary Viewpoint.—A second item is that a draughtsman in laying out his perspective assumes, according to the convention, that his single viewpoint is stationary. In reality, however, an observer in forming his image of a building, assumes a series of viewpoints. In seriously studying a building, one will purposefully view it from many different angles; but even if the interest is only casual one will instinctively look at it more than once—always from a viewpoint which is, of necessity, slightly altered. In all cases, it may be said that the image which the observer takes away with him is not the single first impression received from a literally stationary viewpoint, but is a composite of several distinct impressions. This composite quality of the image is an essential which demands the renderer's attention: how he may, by a cunning draughtsmanship, convey this aspect of the case is considered in this article under the heading of "Procedure."

The foregoing consideration involves a problem that often appears in rendering; viz., one is often faced with the necessity of choosing between a truthful pictorial statement of the building which is being drawn and a truthful statement of the viewpoint which happens to have been chosen.

It is usually held that when a viewpoint has once been selected, it is demanded by honesty that all items of the scene (including adjoining buildings) must be delineated exactly as they appear; that if one arbitrarily makes alterations (as, for example, showing adjoining buildings less prominently than they actually are) he is guilty of "faking." Undeniably, many renderings are "faked"; at the same time, there is a distinction to be made. If the alteration has been made for the purpose of conveying a more favourable impression than the actual scene, then the charge of misrepresentation is, obviously, sustained. It often happens, however, that a building possesses a very important feature which, while entirely visible from many points of view, may happen to be screened from the particular point of view that has been chosen. For instance, a building may possess a certain buttressing member which gives its tower integrity, and which may be visible from many viewpoints, but this member may be hidden from the chosen viewpoint by some extraneous and perhaps temporary obstruction. We may assume at the same time, that the renderer's commission is to depict the building as truthfully and completely as possible in a single drawing. In such a case, it would appear that he is not so much permitted as actually required to slight incidental facts of his viewpoint in favour of the essential facts of the subject which he is viewing.

Perspective of Vertical Lines.—Another item demanding the renderer's attention is that all effects of perspective which a building presents to the human eye apply to its vertical as well as to its horizontal extension. Although this is obviously so, the current convention of perspective generally disregards it, the horizontal lines, only, being drawn to meet in a "vanishing point" but the vertical lines being arbitrarily drawn parallel to each other. In the case of very low buildings, the discrepancy is not important; but in the cases, now so numerous, of very tall buildings, the inaccuracy is serious. The convention not only produces distorted drawings, but so habituates onlookers to distortion that they become disinclined to recognize normal appearances.

Method of Construction.—The renderer may, to a considerable degree, express in his drawing such differences of appearance as exist, for example, between a building of solid masonry and one of steel grille construction. His medium allows considerable variety of indication of texture characteristic of stone, brick, terracotta, glass, etc.;

Atmospheric Conditions.—Buildings are, of necessity, seen through a physical atmosphere and a suggestion of reality obviously cannot be conveyed in a drawing in which an atmospheric condition is not convincingly suggested; some renderings, for instance, fail by conveying the suggestion that the subject was viewed through a vacuum.

The important question of colour belongs to a general study of the painter's art (see PAINTING; WATERCOLOUR PAINTING).

In addition to these material factors, an architectural subject presents others of a psychological nature. A realistic rendering may, indeed, be produced by dealing honestly with only the physical facts; an authentic rendering, however, demands a realistic treatment of intellectual and emotional aspects as well. In this connection, the following experiment is illustrative. An exact perspective was laid out of the form of the Woolworth building, using the architect's blue prints as a basis. A second study was made, sketching from the building itself from an exactly corresponding viewpoint. The building was then photographed from this viewpoint. On comparing the three results it was found that the principal proportions were different in each case. The more striking conclusion was that none of them conveyed the sense of structural logic which the disposition of the steel members themselves conveys to the thoughtful observer; none of them suggested the emotion of soaring aspiration which the form itself suggests to the human onlooker. It becomes, indeed, one of the chief concerns of the renderer to comprehend the nature of the architectural idea which his subject embodies, the trend of thought the architect has expressed. Similarly, the renderer must especially aim to appreciate the emotional tone, the particular mood, of his subject. On entering these outlying psychological domains rendering, like the other arts, may attain its happiest freedom of movement. Yet just here, unfortunately, it must evade competent technical guidance. We have many paintings and drawings which succeed in conveying an isolated thought or an isolated emotion; but too often we find that the renderings which have attained this success have paid in distorted material proportions.

Viewed in this way, renderings as a whole fall into certain rather well-defined groups. The largest, and most familiar, includes those in which the renderer has made a competent presentation of the material facts, but has failed to include any of those elements which, in architecture, stimulate the mind and arouse the emotions. It is as though he worked only with his hands, neither his thought nor feeling having been involved. The result is correct but chilling. A second group is that in which only an emotional aspect of the subject has been fully rendered, just as a third is that in which only an intellectual aspect has been emphasized. Such works, generally labelled "impressionistic," "futuristic," etc., often convey what was intended yet fail of permanent value in that they distort or omit the physical facts of the case. If, for example, the subject be a mausoleum which has, in actuality, an atmosphere of solemnity, such a rendering may—perhaps in a few dark washes—convey an emotion of solemnity but leave the mausoleum itself in doubt. Or, if the subject be a tower notable for its logical growth, the rendering may—perhaps in a few cold lines—suggest logical growth but refer to no particular tower. There follow, naturally, three further groups in which the result is more appealing or convincing: that in which the material facts have been accurately presented in a thoughtful manner; that in which they have been presented with appreciable emotion; and that in which, while the material facts have been presented inexactly, a clear architectural thought appears accompanied by deep feeling. The ideal, which would constitute a seventh group, would be to convey the material, the emotional and the intellectual facts in the same rendering.

Why renderings should fall into these various groups is probably not difficult to ascertain: they do so by following the various personalities of the renderers. A draughtsman naturally draws that aspect of a building which he is by habit inclined to appreciate. From one renderer, we shall almost always get a very correct and cold drawing; from another a very bold and incorrect drawing. This suggests the reason why a perfectly balanced rendering has never been produced. It also suggests a point of interest to the

student of rendering. It may well be that he will develop his art not simply by cultivating whatever tendency he happened to exhibit in the beginning, but, rather, by seeking to add to his forces some tendency which was not habitual to him. For example, if he is in the way of being an excellent draughtsman, he might seek to acquire an emotional appreciation of architecture in addition; just as, if he has always had strong feelings about buildings, he might seek to comprehend the pure logic by which all architectural masterpieces are given form. When thus regarded, rendering becomes, for the renderer himself, not so much a matter of self-expression as of self-development.

PROCEDURE

To answer the remaining question—*how* to make a rendering—it is necessary, since there are numerous equally promising methods of procedure, to describe the method employed in a specific case. In the case of the rendering reproduced in fig. 2-6 of Plate III the procedure was as follows:—

A sheet of mounted Whatman paper 27 by 40 in. was tacked to a slightly larger drawing board and placed on a vertical easel. The draughtsman standing before the easel, made the assumption that, for the moment, the paper represented *space*. With the intention of introducing into this space, the presence of *mass*, a number of lines were lightly sketched in, using a 3B Wolf crayon (see fig. 1). These lines fall into three groups, according to their direction; they proceed, respectively, from three previously assumed "vanishing points" (see PERSPECTIVE). They serve the draughtsman as an adequate notation of the three-dimensionality which characterizes any mass in space. While sketching these generalized lines, he emphasized such as would tentatively indicate the particular form that he intended to give the mass—the form which, until now, had existed only in his mind. The next step was to confirm and solidify these outlines by introducing tone values—produced by drawing, rapidly, a number of freehand lines across the areas to be shaded (see fig. 2) and rubbing these lines together into a tone with a gloved finger or a paper "stump" (see fig. 3). In the rendering now under consideration, the degree of solidity which was desired at this stage was effected by producing three general tones—the background being the darkest, the planes of the building which face toward the left being intermediary, and the planes which face toward the right being the lightest. The last tone was produced by cleaning the areas with a "kneaded" eraser (see fig. 4).

At this point, the draughtsman had before him a visualization, vivid enough for his own purposes, of the basic form of the building. His next step was to identify, in his mind, the principal subdivisions of his preconceived design and to indicate, on the paper, these modifications of the basic form. This involved a repetition, at a smaller scale, of his previous procedure; that is to say, he first sketched in the minor forms in line and then solidified them with tone values, using glove, stump and eraser. At this point another tone value was added to contribute further to the effect of solidity; i.e., the cast shadows (see fig. 5). The same process of indicating form in line was repeated again and again—each time dealing with a category of smaller forms—until the building appeared in that degree of detail which seemed best calculated to serve the purposes for which the drawing was undertaken (see fig. 6).

Of renderings of this sort, it might be said that the draughtsman begins his task in this spirit; he is, metaphorically, facing a building which, although it exists in its entirety, is completely hidden from him in a mist or fog. As he approaches his subject, however, he begins to discern the principal outlines of its mass. Soon its secondary and tertiary features appear. He is free to continue his approach until the most minute details have become plain. Nevertheless, it is important that he halt at that point where his subject has revealed all that is essential to his inquiry.

The numerous other methods of rendering, all equally useful, can best be studied in reproductions of actual renderings; such material, with explanatory notes, is shown in the accompanying plates. They all point to the same conclusion—the draughtsman's best procedure is first to delineate the essentials of his subject, then to build all indication of detail on this foundation.

(H. F.)

RENSBURG, a town in the Prussian province of Schleswig-Holstein, Germany, on the Eider and on the Kaiser Wilhelm canal, 20 mi. W. of Kiel, on the Altona-Flensburg railway. Pop. (1939) 24,749. Rendsburg came into existence under the shelter of a castle founded by the Danes about the year 1100 and was an object of dispute between the Danish kings and the counts of Holstein. In 1252 it was adjudged to the latter and the town was surrounded with ramparts in 1539. The war of 1848-50 began with the capture of Rendsburg by the Holsteiners and it formed the centre of the German operations. In Nov. 1865 the town was occupied by the Saxon troops acting as the executive of the German Confederation, and it was the base of the operations of the Austrians and Prussians against Schleswig in the spring of the following year. Rendsburg was jointly occupied by Austrian and Prussian military until 1866, when it fell to Prussia. It consists of three parts—the crowded Altstadt, on an island in the Eider; and new towns on the north and south banks of the river. Its importance rests on the commercial facilities afforded by its connection with the North sea and the Baltic through the Kaiser Wilhelm canal, by which transit trade is carried on in grain, timber, Swedish iron and coals. The principal products are dyes, iron, artificial manures, machines and tobacco.

RENÉ I (1409-1480), duke of Anjou, of Lorraine and Bar, count of Provence and of Piedmont, king of Naples, Sicily and Jerusalem, was born at Angers on Jan. 16, 1409, the second son of Louis II, king of Sicily, duke of Anjou, count of Provence, and of Yolande of Aragon. By his marriage treaty (1410) with Isabella, elder daughter of Charles II, duke of Lorraine, the comte de Guise, as he then was, became heir to the duchy of Bar, which was claimed as the inheritance of his mother Yolande, and in right of his wife, heir to the duchy of Lorraine. René, then only ten, was to be brought up in Lorraine under the guardianship of Charles II and Louis, cardinal of Bar, both of whom were attached to the Burgundian party, but he retained the right to bear the arms of Anjou. When Louis of Bar died in 1430 René came into sole possession of his duchy; and in the next year, on Charles II's death, he succeeded to the duchy of Lorraine. But the inheritance was claimed by the heir-male Antoine de Vaudémont, who with Burgundian help defeated René at Buzenval in July 1431. The duchess Isabella effected a truce with Antoine de Vaudémont, but the duke remained a prisoner of the Burgundians until April 1432, when he recovered his liberty on parole on yielding up as hostages his two sons, John and Louis of Anjou. His title as duke of Lorraine was confirmed by his suzerain, the emperor Sigismund, at Basle in 1434. This proceeding roused the anger of the Burgundian duke Philip the Good, who required him early in the next year to return to his prison, from which he was released two years later on payment of a heavy ransom. He had succeeded to the kingdom of Naples through the deaths of his brother Louis III and of Joanna II (of Durazzo), queen of Naples, the last heir of the earlier dynasty. Louis had been adopted by her in 1431, and she now left her inheritance to René.

The marriage of Mary, daughter of Charles I of Bourbon and niece of Philip of Burgundy, with John, duke of Calabria, René's eldest son, cemented peace between the two princes. After appointing a regency in Bar and Lorraine, he visited his provinces of Anjou and Provence and in 1438 set sail for Naples, which had been held for him by the duchess Isabella. In 1441 Alphonso of Aragon laid siege to Naples, which he sacked after six months' siege. René returned to France in the same year; and though he retained the title of king of Naples his effective rule was never recovered.

René took part in the negotiations with the English at Tours in 1444, and peace was consolidated by the marriage of his younger

daughter, Margaret, with Henry VI at Nancy. René now made over the government of Lorraine to John, duke of Calabria, who was, however, only formally installed as duke of Lorraine on the death of Queen Isabella in 1453. René had the confidence of Charles VII of France (who had married his sister, Mary of Anjou) and is said to have initiated the reduction of the men-at-arms set on foot by the king, with whose military operations against the English he was closely associated. He entered Rouen with him in Nov. 1449 and was also with him at Formigny and Caen. After his second marriage (1454) with Jeanne de Laval, daughter of Guy XIV, count of Laval, and Isabella of Brittany, René took a less active part in public affairs and devoted himself more to artistic and literary pursuits. In 1453 he made an unsuccessful attempt on northern Italy. In 1467 his son John took Barcelona from John II of Aragon and held it till his death in 1470 (see ANJOU).

The king of Sicily's fame as an amateur of painting has led to the attribution to him of many old paintings in Anjou and Provence, in many cases simply because they bear his arms. These works are generally in the Flemish style and were probably executed under his patronage and direction, so that he may be said to have formed a school of fine arts in sculpture, painting, gold work and tapestry. Two of the most famous works once attributed to René are the triptych, the "Burning Bush," in the cathedral of Aix, showing portraits of René and his second wife, Jeanne de Laval, and an illuminated Book of Hours in the Bibliothèque Nationale, Paris. The "Burning Bush" was in fact the work of Nicolas Froment of Avignon. Among the men of letters attached to René's court was Antoine de la Sale, whom he made tutor to his son, the duke of Calabria. He encouraged the performance of mystery plays: On the performance of a mystery of the Passion at Saumur in 1465 he remitted four years of taxes to the town; and the representations of the Passion at Angers were carried out under his auspices. He exchanged verses with his kinsman Charles of Orléans. The best of his poems is the idyll of Regnault and Jeanne, representing his courtship of Jeanne de Laval. *Le Livre des tournois*, a book of ceremonial and the allegorical romance, *Conquête qu'un chevalier nommé le Cœur d'amour epris fist d'une dame appelée Douce Mercy*, with other works, were perhaps dictated to his secretaries or compiled under his direction. He died on July 10, 1480.

RENÉE OF FRANCE (1510-1575), second daughter of Louis XII and Anne of Brittany, was born at Blois on Oct. 25, 1510. After being betrothed successively to Gaston de Foix, Charles of Austria (the future emperor Charles V), his brother Ferdinand, Henry VIII of England, and the elector Joachim II of Brandenburg, she married in 1528 Hercules of Este, son of the duke of Ferrara, who succeeded his father six years later. Renée's court became a rendezvous of men of letters and a refuge for the persecuted French Calvinists. She received Clément Marot and Calvin at Ferrara, and finally embraced the reformed religion. Her husband, however, who viewed these proceedings with disfavour, banished her friends, took her children from her, threw her into prison, and eventually made her abandon at any rate the outward forms of Calvinism. After his death in 1559, Renée returned to France and turned her duchy of Montargis into a centre of Protestant propaganda. During the wars of religion she was several times molested by the Catholic troops, and in 1562 her château was besieged by her son-in-law, the duke of Guise. She died at Montargis.

See B. Pontana, *Renata di Francia* (Rome, 1889 seq.); and E. Rodocanachi, *Renée de France* (Paris, 1896).

RENFREW, royal and small burgh and the county town of Renfrewshire, Scotland, near the southern bank of the Clyde, 7 mi. W. by N. of Glasgow, via Cardonald, by the L.M.S. railway. A small part of the burgh is in the parish of Govan, Lanarkshire. Pop. (1951) 17,093. Industries include large shipbuilding works, engineering, weaving, and the manufacture of hosiery, rubber and soap. The Clyde Trust has constructed a large dock here, and there is a ferry to Yoker. Robert III gave a charter in 1396, but

it was a burgh (Renfry) at least 250 years earlier. Close to the town, on the site of Elderslie House, Somerled, lord of the Isles, was defeated and slain in 1164 by the forces of Malcolm IV, against whom he had rebelled. In 1404 Robert III bestowed upon his son James (afterwards James I of Scotland) the title of Baron of Renfrew, still borne by the Prince of Wales.

RENFREWSHIRE, southwestern county, Scotland, bounded north by the river and Firth of Clyde, east by Lanarkshire, south and southwest by Ayrshire and west by the Firth of Clyde. A small detached portion of the parish of Renfrew, situated on the northern bank of the Clyde, is surrounded on the landward side by Dumbartonshire. The county has a land area of 227.6 sq.mi. The surface is low and undulating, except towards the Ayrshire border on the southwest, where the principal height is Hill of Stake (1,711 ft.), and the confines of Lanarkshire to the southeast, where a few points attain a height of 1,200 ft. The southwestern hills are formed of volcanic rocks, basalts, porphyrites, tuffs and agglomerates of the age of the Calcareous Sandstone series. Practically all the area west of these rocks is occupied by the Carboniferous Limestone series. Boulder clays and glacial gravels and sands cover considerable areas. Much of the higher land in the centre is well wooded. The Clyde forms part of the northern boundary of the shire. In the northwest Loch Thom and Gryfe reservoir provide Greenock with water, and Balgray reservoir and Glen reservoir reinforce the water-supply of a portion of the Glasgow area. Castle Semple Loch and other lakes are situated in the south and southeast. The Glasgow, Paisley and Johnstone canal was converted after 1882 into the track of the Glasgow & South-Western (now L.M.S.) railway. Strathgryfe is the only considerable vale in the shire. The scenery at its head is wild and bleak, but the lower reaches are pasture land. The wooded ravine of Glenkillock, to the south of Paisley, is watered by Killoch Burn, on which are three falls.

History.—At the time of the Roman advance from the Solway the land was peopled by the British tribe of Damnonii. To hold the natives in check the conquerors built in 84 the fort of Vanduam on high ground now covered by houses and streets in Paisley; but after the Romans retired (470) the territory was overrun by Cumbrian Britons and formed part of the kingdom of Strathclyde, the capital of which was situated at Alclyde, the modern Dumbarton. In the 7th and 8th centuries the region practically passed under the supremacy of Northumbria, but in the reign of Malcolm Canmore became incorporated with the rest of Scotland. During the first half of the 12th century, Walter Fitzalan, high steward of Scotland, ancestor of the royal house of Stuart, settled in Renfrewshire on an estate granted to him by David I. Till their accession to the throne the Stuarts identified themselves with the district, which, however, was only disjoined from Lanarkshire in 1404. In that year Robert III erected the barony of Renfrew and the Stuart estates into a separate county, which, along with the earldom of Carrick and the barony of King's Kyle (both in Ayrshire), was bestowed upon his son, afterwards James I. From their grant are derived the titles of earl of Carrick and baron of Renfrew, borne by the eldest son of the sovereign. Apart from such isolated incidents as the defeat of Somerled near Renfrew in 1164, the battle of Langside in 1568 and the capture of the 9th earl of Argyll at Inchinnan in 1685, the history of the shire is scarcely separable from that of Paisley or the neighbouring county of Lanark.

Agriculture and Industries.—The hilly tract contains much peat-moss and moorland, but over those areas which are not thus covered the soil, which is a light earth on a substratum of gravel, is deep enough to produce good pasture. In the undulating central region the soil is better, particularly in the basins of the streams, while on the flat lands adjoining the Clyde there is a rich alluvium, which, except when soured by excessive rain, yields heavy crops. Of the total area, one-half was under cultivation in 1938, and of this about two-thirds was permanent grass. Oats was the chief crop and occupied 7,142 ac.; there were 1,749 ac. of wheat. Potatoes and turnips and swedes (2,515 ac. and 1,451 ac.) were the leading green crops. Near the populous centres some orchards and market gardens are found, and an increasing acreage is under

wood. Horses are kept mostly for farming operations, and the bulk of the cattle are maintained in connection with dairying. Sheep-farming, though on the increase, is not prosecuted so vigorously as in the other southern counties of Scotland, and pig-rearing is on the decline. Of the 1,037 holdings in 1938, one-half were of 50 ac. and under.

Coal, iron and fireclay are the principal minerals of Renfrewshire, and in point of commercial and manufacturing importance the county is second only to Lanark. Granite, limestone and sandstone are quarried. The thread industry at Paisley is very extensive. Cotton and flax spinning, printing, bleaching and dyeing are carried on at Paisley, Renfrew, Barrhead and elsewhere; woollens and worsteds are produced at Greenock and Renfrew. Engineering works and iron foundries are found at Greenock, Port Glasgow, Paisley, Renfrew, Barrhead and Johnstone. Sugar is a staple article of trade in Greenock and there are chemical works at Cathcart, Paisley, Hurlet and Nitshill. Brewing and distilling are carried on at Greenock and other places. Shipbuilding is especially important at Greenock and Port Glasgow. Paper mills are established in Greenock, Cathcart and Johnstone. Numerous miscellaneous industries—such as the making of starch, comflour, earthenware and soap are important in Paisley and elsewhere. Trade and fisheries are centred at Greenock.

The L.M.S. railway runs westwards from Glasgow by Paisley to Greenock, Gourcock and Wemyss Bay; southwards to Barrhead and other stations; and southwards to Busby. Other lines run to Greenock by Paisley, Johnstone and Kilmacolm; to Nitshill and other places southwards; by Lochwinnoch (for Dalry and Ardrossan in Ayrshire); and to Renfrew jointly with the Caledonian.

Population and Administration.—The population was estimated in 1938 at 317,179. In 1931 Gaelic and English were spoken by 3,061 persons. Thus, though the shire is but 27th in point of size of the 33 Scottish counties, it is fourth in respect of population. The large burghs are Paisley (est. 1938 pop. 91,167), Greenock (81,297) and Port Glasgow (50,783). The small burghs are Johnstone (13,882), Barrhead (12,265), Gourcock (9,170) and Renfrew (16,509), which is the only royal burgh. There are five county districts. The shire returns one member to parliament for the eastern, and another for the western division. Paisley and Greenock return each one member. Renfrewshire forms a sheriffdom with Bute, and there is a resident sheriff-substitute at Paisley and one at Greenock.

RENNENKAMPF, PAUL (1854–1918), Russian general, was born in 1854 and entered the army in 1873. In 1882 he was appointed to the general staff. Promoted to the rank of general in 1900, he distinguished himself in the Russo-Japanese war (1904–05). In 1913 he was appointed to command of the troops in the Vilna military district. In Aug. 1914 he commanded the I army which invaded eastern Prussia. His inaction during the battle of Tannenberg, where the neighbouring army of Samsonov was destroyed on Aug. 26–29 was a bitter disappointment, and he was even suspected of treachery. Personally brave, Rennenkampf, as an army commander, showed himself in the strategic sphere alternately rash and timid, owing to his inability to grasp the situation as a whole. At the beginning of 1915 he was recalled, and later under the pressure of public indignation, dismissed from the service.

In 1918 Rennenkampf was killed by the Bolsheviks.

RENNER, KARL (1870–1950), Austrian politician, was born on Dec. 24, 1870, the son of a peasant, at Dolni-Dunajovice, Moravia. He studied law at the university of Vienna and early attached himself to the Social Democratic party. He became a leader of Neo-Marxism. He was a deputy from 1907, and, as leader of the Social Democrat party, he repeatedly attacked the government. He deeply influenced the movement which preceded the fall of the monarchy. After the collapse he became head of the government, and after the elections had given the Social Democrats and Christian Socialists an overwhelming majority, he formed a coalition ministry, as the leader of which he became the first chancellor of the Austrian republic.

Renner was largely responsible for the decrees of the national assembly which called for the dethronement of the dynasty of

Habsburg-Lorraine and the banishment of all members of this house if they did not submit entirely to the laws of the republic, and he was in charge of the negotiations which led to the emperor Charles leaving Austria in March 1919. He was responsible for thwarting the separatist endeavours of the different provinces and the demands which the Communists, supported by their partisans in foreign countries, made with the object of overthrowing the government. On May 12, 1919, he went to Paris as head of the Austrian delegation to receive the conditions of peace. As the foreign minister, Otto Bauer (*q.v.*), resigned rather than take the responsibility for certain provisions of the treaty, Renner took over the conduct of foreign affairs and signed the Treaty of St. Germain-en-Laye of Sept. 10, 1919. In Dec. 1919 he visited Paris again to depict Austria's miserable situation to her former enemies and to beg, not without success, for help.

Meanwhile, the first coalition ministry had been succeeded in Oct. 1919 by a second, in which Renner was again chancellor and secretary for foreign affairs. Relations between the Austrian government and Hungary, which since the régime of the revolution had been succeeded by a reaction, were very strained. Renner, who, as a Social Democrat, was inimical to the reactionary Hungarian government, refused to grant demands put forward to extradite the Hungarian revolutionaries who had fled to Vienna. This brought him into conflict with the Christian Socialists and their representatives in the cabinet. The coalition broke up in June; but Renner remained in charge of foreign affairs until Oct. 1920. He returned in April 1945 as premier and foreign minister of the Austrian provisional government, and in Dec. 1945 was elected by parliament to be president of the second Austrian republic. He died in Vienna, Dec. 31, 1950.

His principal works are *Grundlagen und Entwicklungsziele der Österreichisch-ungarischen Monarchie* (1905); *Oesterreichs Erneuerung* (1919); *Die Wirtschaft als Gesamtprozess und die Sozialisierung* (1924). (A. F. P.)

RENNES, a town of western France, formerly the capital of Brittany and now the chief town of the department of Ille-et-Vilaine. Pop. (1946) 113,781. Rennes is situated at the meeting of the Ille and the Vilaine and at the junction of several lines of railway connecting it with Paris (232 mi. E.N.E.), St. Malo (51 mi. N.N.W.), Brest (155 mi. W.N.W.). Rennes, the chief city of the Redones, was formerly (like some other places in Gaul) called *Condate* (hence *Condat*, *Condé*), probably from its position at the confluence of two streams. In Roman times it was in Lugdunensis Tertia and became the centre of Roman roads. The oldest chronicles named it *Urbis Rubra* from the bands of red brick in the foundations of its first circuit of walls. Conan le Tort, count of Rennes (late 10th century), subdued the whole province, and his son and successor, Geoffrey, first took the title duke of Brittany. The dukes were crowned at Rennes; and before entering the city by the Mordelaise gate, they had to swear to preserve the privileges of the church, the nobles and the commons of Brittany. In 1356–57 Bertrand du Guesclin saved it from capture by the English. The parliament of Brittany, founded in 1551, held its sessions at Rennes from 1561, they having been previously shared with Nantes. Henry IV entered the city in state on May 9, 1598. In 1675 an insurrection at Rennes, caused by the taxes imposed by Louis XIV, was cruelly suppressed. The parliament was banished to Vannes till 1689, and the inhabitants punished. At the beginning of the Revolution Rennes was again the scene of bloodshed, caused by the discussion about doubling the third estate for the convocation of the states-general. In Jan. 1789 Jean Victor Moreau (afterwards general) led the law students in their demonstrations on behalf of the parliament against the royal government. It was the centre of the operations of the Republican army against the Vendéens. The bishopric, founded in the 5th century, in 1859 became an archbishopric, a rank to which it had previously been raised from 1790 to 1802.

The town was for the most part rebuilt of dark granite on a regular plan after the seven days' fire of 1720. The old town or Ville-Haute occupies a hill bounded on the south by the Vilaine, on the west by the canalized Ille. The Vilaine flows in a deep

hollow bordered with quays and crossed by six bridges leading to the new town or Ville-Basse on its left bank. The cathedral of Rennes was rebuilt between 1787 and 1844 on the site of two churches dating from the 4th century. The Renaissance west façade has twin towers. The archbishop's palace occupies in part the site of the abbey of St. Melaine. The Mordelaise gate is a curious example of 15th century architecture and preserves a Latin inscription of the 3rd century, a dedication by the Redones to the emperor, Gordianus. The finest building in Rennes is the 17th century parliament house, now the law-court.

Rennes is the seat of an archbishop and a prefect, headquarters of the X army corps and centre of an *académie* (educational division). Its university has faculties of law, science and letters and a preparatory school of medicine and pharmacy. The town is also the seat of a court of appeal, of a court of assizes, of tribunals of first instance and commerce, of a board of trade-arbitrators and of a chamber of commerce. Tanning, iron-founding, timber-sawing and the production of furniture and wooden goods, flax spinning and the manufacture of tenting and other coarse fabrics, bleaching and various smaller industries are carried on. Trade is chiefly in butter made in the neighbourhood and in grain, flour, leather, poultry, eggs and honey.

RENNET: see CHEESE; **NETTROT:** *Chemistry of Digestion*.
RENNIE, JOHN (1761-1821), British engineer, was the youngest son of James Rennie, a farmer at Phantassie, Haddingtonshire, where he was born on June 7, 1761. His first engineering work was the erection of flour mills, but his fame chiefly rests on his achievements in civil engineering. His skill solved the problem of draining and reclaiming extensive tracts of marsh in the eastern counties and on the Solway Firth. As a bridge engineer he built Waterloo, Southwark and London bridges—the last of which he did not live to see completed (see *Barrages*).

A noteworthy feature in many of his designs was the flat roadway. Among the harbours and docks in the construction of which he was concerned are those at Wick, Torquay, Grimsby, Holyhead, Howth, Kingstown and Hull, together with the London dock and the East India dock on the Thames, and he was consulted by the government in respect of improvements at the dockyards of Portsmouth, Sheerness, Chatham and Plymouth, where the breakwater was built from his plans. He died in London on Oct. 4, 1821, and was buried in St. Paul's.

See J. Rennie, *Autobiography of Sir John Rennie*, F.R.S. (1875).

RENO, the largest city of Nevada, U.S., and the county seat of Washoe county; on the Truckee river, 14 mi. from the western boundary of the state. It is on federal highways 40, 50 and 395; has a privately owned airport, operated by United Air Lines; and is served by the Southern Pacific and the Western Pacific railways and by freight truck and bus lines. Pop. (1950) 32,378. The city covers 5.9 sq. mi., at an altitude of 4,500 ft., near the foot of the Sierra Nevada range, amid magnificent and varied scenery. It is the financial, educational and professional centre of the state and the commercial centre for the adjacent districts of California as well as for Nevada. The volume of retail business in 1949 was \$77,500,000; wholesale, \$44,000,000; manufacturing, \$30,000,000.

In Sparks, practically adjoining Reno on the east (pop. 1950, 8,170), are extensive shops of the Southern Pacific railroad. Bank debits for the city of Reno totalled \$174,300,000 in 1940 while in 1949 the total was \$276,326,000.

The University of Nevada (opened at Elko in 1873 and moved to Reno in 1885) occupies a 60 ac. campus on a low plateau overlooking the city. Adjoining the campus is the 60 ac. farm of the agricultural experiment station, given by the citizens of Washoe county to the state in 1899.

The Mackay school of mines was founded in 1907 by Mrs. John W. Mackay and Clarence H. Mackay in memory of John W. Mackay, one of the pioneers of the Comstock lode. Affiliated with the university are the Nevada agricultural experiment station (1887), the state analytical laboratory (1895), the state hygienic laboratory (1909), the state laboratory for pure food and drugs and weights and measures (1909), the state veterinary control service (1915), and one of the 12 experiment stations of the United States bureau of mines, handling all the in-

vestigations for the United States on gold, silver, platinum and the rare metals (1919). The state hospital for mental diseases (1882) is located between Reno and Sparks. St. Mary's (Catholic) and Washoe county general (public) hospitals give service covering a wide area. Because of the relative ease with which a divorce may be secured in Nevada (the law recognizing seven grounds for an absolute decree and requiring only six weeks' residence before bringing suit) Reno is the temporary residence of many persons from New York and other states with less liberal laws on the subject. About 25 mi. S.E. of the city are the famous mining camps of Virginia City and Gold Hill, on the Comstock lode. In 1859 (the year the Comstock lode was discovered) a roadhouse was built on the site of Reno for the accommodation of travellers and freight-teams on the Overland Route and to the goldfields. By 1863 the place had become known as Lake's Crossing, and five years later it was chosen for a station on the Central (now the Southern) Pacific railroad, then building through the Truckee valley. It was named after General Jesse Lee Reno (1823-62), a Federal officer in the Civil War. The town was incorporated in 1879, and was chartered as a city in 1890 and again in 1903. In 1875 and in 1879 it suffered from destructive fires.

RENOIR, PIERRE AUGUSTE (1841-1919), French painter, was born at Limoges on Feb. 25, 1841. He was the son of a tailor. At 13 he was apprenticed to a manufacturer of porcelain, and in painting on china he acquired a taste for pure and transparent colour and subtle brushwork. After earning some money in painting fans and blinds he entered the studio of Gleyre, where he became the friend of Sisley and Monet. He was inspired by Courbet to study nature; he was interested in Delacroix's colour technique; and the work of Monet and Corot appealed to him. In his early work he followed, with pronounced modern modifications, certain traditions of the French 18th century school. In the work of a later period colour was made subservient to form under the influence of Ingres, and his search for volume and form induced him at the end of his life to take up modelling. In the '70s he threw himself into the impressionist movement and became one of its leaders. Renoir tried his skill in almost every genre—in portraiture, landscape, flower-painting, scenes of modern life and figure subject; he excelled in painting nude figures of women. His art breathes sensuality, transfigured by lyrical feeling and plastic sense. His finest works rank among the masterpieces of the modern French school. Among these are some of his nude "Bathers," the "Rowers' Luncheon," the "Ball at the Moulin de la Galette," "The Box," "The Terrace," "La Pensive," and the portrait of "Jeanne Samary." He is represented in the Sallebotte room at the Luxembourg, in the collection of M. Durand-Ruel, and in most of the collections of impressionist paintings in France, in the United States, in Germany and in the Tate gallery, London.

Renoir died on Dec. 17, 1919, at Cagnes in Provence, where he had settled in 1900.

See A. Vollard, *La Vie et l'Œuvre de Pierre-Auguste Renoir* (1919) and *Impressionism*; F. Fosca, *Renoir* (Eng. trans., 1924).

RENOUF, SIR PETER LE PAGE (1822-1897), Egyptologist, was born in Guernsey, on Aug. 25, 1822. He was educated at Elizabeth College there, and proceeded to Oxford, which, upon his becoming a Roman Catholic, under the influence of Dr. Newman, he quitted without taking a degree. He took an active part in church controversy, and his treatise (1868) upon the condemnation of Pope Honorius for heresy by the council of Constantinople in A.D. 680 was placed upon the index of prohibited books. After holding various educational posts he became in 1866 Keeper of Oriental Antiquities in the British Museum, in succession to Samuel Birch. He was also elected in 1887 president of the Society of Biblical Archaeology, to whose *Proceedings* he contributed, among other important papers, the translation of *The Book of the Dead*, with a commentary. He retired in 1891, and died in London on Oct. 14, 1897.

RENOUVIER, CHARLES BERNARD (1815-1903), French philosopher, was born at Montpellier on Jan. 1, 1815, and died on Sept. 1, 1903. His two leading ideas are a dislike for the unknowable, and a reliance on the validity of personal experience.

The former accounts for his acceptance of Kant's phenomenalism, combined with rejection of the "thing in itself." It accounts, too, for his polemic on the one hand against a Substantial Soul, a Buddhist Absolute, an Infinite Spiritual Substance; on the other hand against the no less mysterious material or dynamic substratum by which naturalistic Monism explains the world. He holds that nothing exists except presentations, which are not merely sensational, and have an objective aspect no less than a subjective. To explain the formal organization of our experience he adopts a modified version of the Kantian categories. The insistence on the validity of personal experience leads Renouvier to a yet more important divergence from Kant in his treatment of volition. Liberty, he says, in a much wider sense than Kant, is man's fundamental characteristic. Human freedom acts in the phenomenal, not in an imaginary noumenal sphere. Belief is not intellectual merely, but is determined by an act of will affirming what we hold to be morally good. In his religious views Renouvier makes a considerable approximation to Leibnitz. He holds that we are rationally justified in affirming human immortality and the existence of a finite God who is to be a constitutional ruler, but not a despot, over the souls of men. He would, however, regard atheism as preferable to a belief in an infinite Deity. His chief works are: *Essais de critique générale* (1854-64); *Science de la morale* (1869); *Uchronie* (1876); *Esquisse d'une classification systématique des doctrines philosophiques* (1885-86); *Philosophie analytique de l'histoire* (1896-97); *Histoire et solution des problèmes métaphysiques* (1901); *Victor Hugo. Le Poète* (1893); *Le Philosophe* (1900); *Les Dilemmes de la métaphysique pure* (1901); *Le Personnalisme* (1903); *Critique de la doctrine de Kant* (1906, published by L. Prat).

See L. Prat, *Les Derniers entretiens de Charles Renouvier* (1904); M. Ascher, *Renouvier und der französische Neo-Kriticismus* (1900); E. Janssens, *Le Néocriticisme de C. R.* (1904); A. Darlu, *La Morale de Renouvier* (1904); G. Séailles, *La Philosophie de C. R.* (1903); A. Arnauld, *La Philosophie religieuse de C. R.* (1907).

RENSSELAER, a city of Rensselaer county, New York, U.S.A., on the east bank of the Hudson river, opposite Albany. It is on federal highways 9 and 20 and is served by the New York Central railway; it is a part of the deep-water port of Albany (q.v.) and shares in the other transportation facilities of that city.

The population in 1950 was 10,856; in 1940 it was 10,768 by federal census. It has large railroad shops; among the leading manufactures are chemicals, dyes, shirts, woollen products and petroleum.

A settlement called Greenbush was established there in 1631, on the large tract known as Rensselaerwyck. In 1820 a square mile of land within the present city limits was acquired by a speculator, who divided it into lots and offered them for sale, and in 1815 the village was incorporated. In 1897 it was chartered as a city under its present name.

RENT. Various species of rent appear in Roman law (q.v.). In English law rent is a certain and periodical payment or service made or rendered by the tenant of a corporeal hereditament and issuing out of (the property of) such hereditament. Its characteristics, therefore, are (1) certainty in amount; (2) periodicity in payment or rendering; (3) the fact that rent is yielded and is, therefore, said "to lie in render," as distinguished from *profits à prendre* in general, which are taken, and are, therefore, said to lie in *prendre*; (4) that it must issue out of (the profits of) a corporeal hereditament. A rent cannot be reserved out of incorporeal hereditaments. But rent may be reserved out of estates in reversion or remainder (see LAWS RELATIVE TO REAL PROPERTY AND CONVEYANCING) which are not purely incorporeal. It is not essential that rent should consist in a payment of money. Apart from the rendering of services, the delivery of hens, horses, wheat, etc., may constitute a rent. But at the present day, rent is generally a sum of money paid for the occupation of land. It is important to notice that this conception of rent was attained at a comparatively late period in the history of the law. The earliest rent seems to have been a form of personal service, and was fixed by custom. Rent service is the oldest kind of existing rent. It is the only one to which the power of distress

attaches at common law, giving the landlord a preferential right over other creditors exercisable without the intervention of judicial authority (see DISTRESS). The increasing importance of socage tenure, arising in part from the convenience of paying a certain amount, whether in money or kind, rather than comparatively uncertain services, led to the gradual evolution of the modern view of rent as a sum due by contract between two independent persons.

Classes of Rents.—Rents, as they now exist in England, are divided into two great classes—rent service and rent charge. A rent service is so called because by it a tenure by means of service is created between the landlord and the tenant. The service is now represented by fealty, and is nothing more than nominal. Rent service is said to be incident to the reversion—that is, a grant of the reversion carries the rent with it (see REMAINDER). A power of distress is incident at common law to this form of rent. A rent charge is a grant of an annual sum payable out of lands in which the grantor has an estate. It may be in fee, in tail, for life—the most common form—or for years. A rent charge may also be granted out of another rent charge (Law of Property Act, 1925, s. 7, 122 [1]). A rent charge must be created by deed or will, and might be either at common law or under the Statute of Uses (1536). As from Jan. 1, 1926, a rent charge may be created or reserved without the intervention of a use (Law of Property Act, 1925, s. 65, 187). The grantor has no reversion, and the grantee had at common law no power of distress, though such power was given him by the instrument creating the rent charge. Annual sums charged on land by way of rent charge may be recovered (a) if unpaid for 21 days, by distress; (b) if unpaid for 40 days, by entry into possession of the land and appropriation of income, and/or demise. By s. 45 of the Conveyancing Act, 1881, a power of redemption of certain perpetual rents in the nature of rent charges is given to the owner of the land out of which the rent issues. Rent charges granted since April 26, 1855, otherwise than by marriage settlement or will for a life or lives or for any estate determinable on a life or lives were required, in order to bind lands against purchasers, mortgages or creditors, to have been registered in the Land Registry in Lincoln's Inn Fields (Judgments Act, 1855). After 1925, however, rent charges of this character became equitable interests only, and as such are overreached by conveyances to purchasers of a legal estate in lands (Law of Property Act, 1925, s. 2). There was no need, therefore, to provide for the registration of such rent charges, and the Land Charges Act, 1925, enacted that after Jan. 1, 1926, they should not be entered in the register of annuities (s. 4 [1]). Rent charges in possession charged on land perpetually or for a term of years absolute are "legal estates," registrable as such under the Land Registration Act, 1925 (ss. 2, 3, viii, xiv); and certain classes of rent charge may be entered in the register of land charges under the Land Charges Act, 1925 (s. 10). Rent charges are barred by nonpayment or non-acknowledgment for 12 years (Limitation Act, 1874). The period of limitation for arrears of rent is six years. As to the colonies see Burge, *Col. and For. Laws* (by Bewes, iv., pt. 2, 460).

Forms of rent charge of special interest are *tithe rent charge* (see TITHES), and the rent charges formerly used for the purpose of creating "faggot votes." The device was adopted of creating parliamentary voters by splitting up freehold interests into a number of rent charges of the annual value of 40s., so as to satisfy the freeholders' franchise. But such rent charges were rendered ineffective by the Representation of the People Act, 1884, s. 4, which enacted (subject to a saving for existing rights) that an exception in favour of owners of tithe rent charge that a man should not be entitled to be registered as a voter in respect of the ownership of any rent charge.

A rent charge reserved without power of distress is termed a *rent-sock* (*radicus siccus*) or "dry rent," from the absence of the power of distress. But, as power of distress for *rents-sock* was given by the Landlord and Tenant Act, 1730, the legal effect of such rents has been since the act the same as that of a rent charge.

Other Varieties of Rent.—*Rents of assize* or *quit rents* are a

relief of the old customary rents. They are presumed to have been established by usage, and cannot be increased or diminished. Provision was made in 1922 for the extinction after 1925 of quit rents and other manorial incidents (Law of Property Act, 1922, ss. 128, 144).

Fee farm rents are rents reserved on grants in fee. They, like quit rents, now occur only in manors, unless they existed before the statute of *Quia Emptores* was enacted or created by the Crown. A rent which is equivalent or nearly equivalent in amount to the full annual value of the land is a *rack rent*. As to ground rent, see *GROUND RENT*. A *dead rent* is a fixed annual sum paid by a person working a mine or quarry, in addition to royalties varying according to the amount of minerals taken.

The object of a dead rent is twofold—first, to provide a specified income on which the lessor can rely; secondly (and this is the more important reason), as a security that the mine will be worked, and worked with reasonable rapidity. *Rents in kind* still exist to a limited extent. All *peppercorn*, or nominal, rents seem to fall under this head. The object of the peppercorn rent is to secure the acknowledgment by the tenant of the landlord's right. In modern building leases a peppercorn rent is sometimes reserved as the rent for the first few years. *Labour rents* are represented by those cases, not unfrequent in agricultural leases, where the tenant is bound to render the landlord a certain amount of team work or other labour as a part of his rent.

As to the apportionment of rents, see *APPORTIONMENT*, and as to the rent of apartments, etc., see *LOUGER AND LODGINGS*.

Payment of Rent.—Rent is due in the morning of the day appointed for payment, but a tenant is not in arrears until after midnight on that day. Rent made payable in advance by agreement between a landlord and his tenant is called *forehand rent*. It is not uncommon in letting a furnished house, or as to the last quarter of the term of a lease of unfurnished premises, to stipulate that the rent shall be paid in advance. As soon as such rent is payable under the agreement the landlord has the same rights in regard to it as he has in the case of ordinary rent. Where a cheque in payment of rent is lost in the course of transmission through the post, the loss falls on the tenant, unless the landlord has expressly or impliedly authorized it to be forwarded in that way; and the landlord's consent to take the risk of such transmission will not be inferred from the fact that payments were ordinarily made in this manner in the dealings between the parties. A tenant may deduct from his rent (i) the "landlord's property tax" (on the annual value of the premises for income tax purposes), which is paid by the tenant, if the statute imposing the tax authorizes the deduction (which should be made from the rent next due after the payment); (ii) taxes or rates which the landlord had undertaken to pay but had not paid, payment having thereupon been made by the tenant; (iii) payments made by the tenant which ought to have been made by the landlord, e.g., rent due to a superior landlord; (iv) compensation under the Agricultural Holdings Act, 1923 (s. 37), and Landlord and Tenant Act, 1927 (s. 11 [2]).

A landlord's main remedy for non-payment of rent is *distress* (*q.v.*). Besides distress the landlord has his ordinary remedy by action. In addition, special statutory remedies are given in the case of tenants holding over after the expiration of their tenancy (see *EJECTMENT*). Under the Rent Restriction Acts, 1920-25, landlords of dwelling houses to which these statutes apply were prevented during their continuance from effectually raising the rents above specified limits, and except in certain cases from recovering possession on the termination of the tenancy. The act of 1920 expired in England on Dec. 25, 1927, and in Scotland on May 28, 1928. The provisions of Pt. II. of the act of 1923 continue in force for five years from the expiration of the act of 1920. (See further *LANDLORD AND TENANT*.)

Under the Landlord and Tenant Act, 1927, the landlord of trade premises may offer a renewal of the tenancy at such rent as, failing agreement, the statutory tribunal may consider reasonable, as an alternative to compensation for improvements (s. 2 [1] [d]) or goodwill (s. 4 [1]). The tenant of such premises may also apply for a new lease at a rent similarly approved (s. 5).

Scotland.—Rent is properly the payment made by the tenant to the landlord for the use of lands held under lease (see *LANDLORD AND TENANT*). In agricultural tenancies the legal terms for the payment of rent are at Whit Sunday after the crop has been sown, and at Martinmas after it has been reaped. But a landlord and tenant may substitute conventional terms of payment, either anticipating (*fore or forehand rent*) or postponing (*back or backhand rent*) the legal term. The rent paid by vassal to superior is called *feu-duty* (see *FEU*). Its nearest English equivalent is the *fee farm rent*. The remedy of distress does not exist in Scots law. Rents are recovered (i.) by summary diligence, proceeding on a clause, in the lease, of consent to registration for execution; (ii.) by an ordinary petitory action; (iii.) by an action of "mails and duties" (the rents of an estate in money or grain: "mails" was a coin at one time current in Scotland) in the Sheriff Court or the Court of Session; and (iv.) in non-agricultural tenancies by procedure under the right of hypothec, where that still exists; the right of hypothec over land exceeding two acres in extent let for agriculture or pasture was abolished as from Nov. 17, 1881; it was also excluded, by the House-letting and Rating (Scotland) Act, 1911 (s. 10), in lets to which that act applies, from all bedding material and all implements of trade used by the occupier and his family and from furniture selected by him up to £10 value (see *DISTRESS; HYPOTHEC*); (v.) by action of removing (see *EJECTMENT*). Arrears of rent prescribe after the expiration of a period of five years reckoned from the time of the tenant's removal from the land.

Labour or service rents were at one time very frequent in Scotland. The events of 1715 and 1745 showed the vast influence over the tenantry that the great proprietors acquired by such means. Accordingly acts of 1716 and 1746 provided for the commutation of services into money rents. Such services may still be created by agreement, subject to the summary power of commutation by the sheriff given by the Conveyancing Act, 1874 (ss. 20, 21). They will no longer be eligible from and after Jan. 1, 1935 (Conveyancing [Scotland] Act, 1924, s. 12 [7]). The Conveyancing (Scotland) Act, 1924, provides (s. 12) for the abolition or commutation of *feu-duties* payable in grain or other fungibles.

United States.—The law is in general accordance with that of England, apart from statute. The tendency of modern State legislation is unfavourable to the continuance of distress as a remedy. In the New England States, attachment on *mesne process* has, to a large extent, superseded it. Alabama, Colorado, Missouri, Montana, North Carolina and Oklahoma have refused to recognize the right of distress upon the ground that the landlord's rights have been secured by the substitution of other remedies. In the District of Columbia, Indiana, Minnesota, New York and Wisconsin it has been abolished by statute. "In those (states) in which it still exists, it has been modified by statutes, the general tendency of which is more or less to withdraw the control of the proceedings from the landlord and to rest it in public officials, thus assimilating it to the process of attachment." (2 Tiffany, Landlord and Tenant, section 325.)

Other Countries.—Under the French Code Civil (art. 2,102) the landlord is a privileged creditor for his rent. If the lease is by authentic act, or under private signature for a fixed term, he has a right over the year's harvest and produce, the furniture of the house and everything employed to keep it up, and (if a farm) to work it, in order to satisfy all rent due up to the end of the term. If the lease is not by authentic act nor for a specified term, the landlord's claim is limited to the current year and the year next following (see *law* of Feb. 12, 1872). The goods of a sub-lessee are protected; and goods bailed or deposited with the tenant are in general not liable to be seized. The French law is in force in Mauritius, and has been reproduced in substance in the Civil Codes of Quebec (arts. 2,005 *seq.*) and St. Lucia (arts. 1,888 *seq.*). There are analogous provisions in the Spanish Civil Code (art. 1,992). The subject of privileges and hypothecs is regulated in Belgium by a special law of Dec. 16, 1851; and in Germany by ss. 1,113 *seq.* of the Civil Code. The law of British India as to rent (Transfer and Property Act, 1882) and distress

(cf., e.g., Act 15 of 1882) is similar to English law. The British dominions generally tend in the same direction. See, e.g., New South Wales (the consolidating Landlord and Tenant Act, 1899, and Act 66 of 1915); Union of South Africa (Act 30 of 1921); Newfoundland (Act 4 of 1899); Ontario (Act 1 of 1902, s. 22, giving a tenant five days for tender of rent and expenses after distress); Jamaica (Law 17 of 1900, certification of landlord's bailiffs); Queensland (Act 15 of 1904). English rent restriction legislation was followed in British India (e.g., Bombay, No. 3 of 1925; Burma, No. 1 of 1925) and in many of the colonies and dominions (e.g., Hongkong, No. 8 of 1925; Malta, No. 1 of 1925; New Zealand, No. 3 of 1925).

RENT: IN ECONOMICS. In economics, rent is the name given to the income which the owner of a productive instrument gets by using it himself or by exacting a payment from another user. Much of the importance of the general theory of rent in economics comes from its application to the special case of income derived from land ownership. In the case of the incomes yielded by the ownership of reproducible instruments of production the principle of rent is subordinate, in the long run, to the principles which govern the rate of interest on capital, for the supply of such instruments will be maintained and increased if, but only if, the prospective return is sufficient to induce the investment of capital. At any given time, however, the income-yielding power of reproducible instruments of production is determined, not by what they cost, but by the value of their productive uses. That is, it is governed by the laws of rent. The specific hypothesis upon which the significance of the principle of rent depends is that the supply of the productive instruments which yield rent may be assumed to be given or fixed, so that the question remains only of how they may best be used.

Rent is generally held to have two distinguishing characteristics: first, it is a differential or graded return; second it is a surplus above costs. That it is a differential return depends upon the circumstance that productive instruments are described or measured in units (e.g., acres) which are not themselves units of productive efficiency. It is obvious that if one acre of agricultural land is better (more fertile or nearer to the market) than another it will command a larger rent. It is also obvious that the rent which any given piece of land commands may be taken to be a measure of its differential superiority over land which just falls short of being good enough to be worth using. That rent may be regarded as a surplus over costs is a consequence of the circumstance that the supply of rent-yielding instruments is taken as given. Even if they were produced or improved (as land is improved) at a cost in the past, their past costs have no relevance to the practical question of how and for what purposes the instruments shall be used. The only costs which need to be taken into account are the costs of using them.

Rent's Relation to Product.—Why, then, should rent be paid? The reason is that rent-yielding productive instruments, including rent-yielding land, exist in limited quantities, in the sense that if any one unit of them were withdrawn from use the aggregate product would be smaller. The rent of a given piece of land or of a given farm tends to be approximately equal to the value of the amount of product which is dependent upon using it. This amount can be determined by comparing the product which the given piece of land or farm will yield under proper cultivation with the product which could be got by employing the same amount of capital and labour on the best land which is not good enough to yield a rent (i.e., at the "extensive margin of cultivation") or by employing it in cultivating rent-yielding lands more intensively (i.e., at the "intensive margin of cultivation").

When the supply of a particular class of rent-yielding productive agents cannot be increased as rapidly as the demand for the products which they yield increases, they will command higher rents. Furthermore, unless there are compensating improvements in productive technique, production can be increased under such circumstances only by using instruments which had previously been below the level of profitable use or by making more intensive use of the latter instruments, i.e., by increasing the labour and other types of instruments used in conjunction with them. Whichever method is followed, increasing costs are encountered. This circumstance is the basis of the doctrine that with a fixed supply of land an increased agricultural product can be had only at the expense of a more than proportionate outlay of labour and capital—a doctrine to which the name, "law of diminishing returns," has been given.

When economists refer to some other form of income or gain, not derived from the ownership of land or of other productive instruments, as rent, they generally mean either that it may be looked upon as a differential return or that it may be conceived to be a surplus above costs. Thus, "rent of ability" is a name sometimes given to the differential element in personal earnings. "Entrepreneur's rent" denotes the profits of an ably-managed and successful enterprise, conceived of as a differential above the return secured by a marginal undertaking which is barely able to meet its costs. "Consumer's rent" is the difference between the amount which the consumer pays and the value which he attaches to what he buys, as measured by the maximum amount which he would have been willing to pay if required. Similarly, "producer's rent" is the difference between what the state of the market enables the producer to get for his goods and the amount which would have sufficed to induce him to produce them. (See also ECONOMICS and LAND.) (A. Yo.)

RENTON, a manufacturing town in Cardross civil parish, Dumbartonshire, Scotland. Pop. (1931) 4,562. It is on the Leven, 2 mi. N.W. of Dumbarton by the L.M.S. & L.N.E. railways. The leading industry is Turkey red dyeing, and calico-printing and bleaching are also carried on. The town was founded in 1782 by Mrs. Smollett (sister of Tobias Smollett); it was named after Cecilia Renton who became her daughter-in-law.

RENTON, a city in King county, western Washington, U.S., about 12 mi. S.E. of Seattle.

It is on U.S. highway 10 and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Northern Pacific and the Pacific Coast railroads.

The population of Renton was 16,039 in 1950; it was 4,488 in 1940 and 4,062 by the census of 1930.

Renton, which is in a fertile area covering the flats of the Cedar river and on the south shore of Lake Washington, is an important trading centre as well as an industrial and agricultural community. A large plant of the Boeing Airplane company is located there. Lumber, shingles, steel products, railroad freight and refrigerator cars, logging machinery and stokers are also manufactured, and there are clay pits, coal mines and railroad shops.

Truck farming is carried on and there is some poultry farming.

Coal was discovered there in the middle of the 19th century, and in 1873 a coal company began to operate the mines. Prominent in the foundation of the company was William Renton, for whom the city is named. Renton, which is incorporated, is administered by a mayor-council form of government with direct popular election.

RENTSCHLER, HARVEY CLAYTON (1881-1949), U.S. physicist, was born at Hamburg, Pa., on March 26, 1881. He was graduated from Princeton university, Princeton, N.J., in 1903 and took his master's degree there the following year. He received the Ph.D. degree from Johns Hopkins, Baltimore, Md., in 1908. Immediately afterwards, he became an instructor in physics at the University of Missouri, Columbia, Mo., and remained there until 1917, rising to the rank of associate professor.

He then accepted the position of director of research in the lamp division of the Westinghouse Electric and Manufacturing Co. at Bloomfield, N.J. There, out of experimental work in photochemistry on the case hardening of steel came his important contribution to medicine and food preservation, the sterilamp ("Bactericidal Effect of Ultraviolet radiation," *J. Bact.* 41:745-774, 1941). The lamp is a gaseous-conductor tube generating radiant energy, i.e., ultra-violet rays with a wave length of 2,537 angstrom units. Such irradiation prevents spoilage through mould and yeast spores, and after tests proved satisfactory, lamps were installed in the processing and storage places of meat, bakery, dairy and brewing establishments. Although the work, which was done in association with Dr. Robert F. James, a biochemist at Westinghouse, was carried on with food preservation in mind, its medical application was also considered. In surgery, though the staff and material be germfree, the air contains bacteria which may infect the patient. Lamps were installed experimentally in the operating room of the Duke university hospital. Results proved postoperative infection and temperatures to be lower, and the lamps were subsequently installed at the Mayo Clinic, the N.Y. Medical Center and elsewhere. Dr. Rentschler also developed an ultra-violet light meter and conducted researches on the photoelectric emission from metals, the preparation and properties of ductile thorium and uranium, and the resonance and ionization of monatomic gases. He was made honorary D.Sc. by Princeton university in 1941, and the following year the honorary degree of doctor of laws was conferred on him at Ursinus college, Collegeville, Pa. His early researches with the refinement of uranium were credited with Westinghouse Electric's ability to provide the first batches of that element for atom bomb experiments in 1943. He died March 23, 1949, at East Orange, N.J.

RENWICK, EDWARD SABINE (1823-1912), U.S. inventor, was born in New York city on Jan. 3, 1823, the youngest son of James Renwick (q.v.) (1792-1863). He was graduated from Columbia college in 1839 and took his master's degree there in 1842. After several years of employment as an engineer, he went to Washington, D.C., where in 1849 he became associated with Peter H. Watson as patent expert in the U.S. circuit courts. Six years later he returned to New York where he worked independently in the same field. Renwick was also an inventor of some note. Among his accomplishments were a self-binder to improve the McCormick reaper (1851-53), an automatically heated and ventilated incubator for the raising of chicks and a chicken brooder (1877-86). He died at Short Hills, N.J., on March 19, 1912.

RENWICK, JAMES (1662-1688), Scottish covenanting leader, was born at Moniaive in Dumfriesshire, on Feb. 13, 1662, the son of a weaver, Andrew Renwick. Educated at Edinburgh university, he joined the section of the Covenanters known as the Cameronians about 1681 and soon became prominent among them. Afterwards he studied theology at the university of Groningen and was ordained a minister in 1683. Returning to Scotland "full of zeal and breathing forth threats of organized assassination," says Andrew Lang, he became one of the field-preachers and was declared a rebel by the privy council. He was largely responsible for the "apologetical declaration" of 1684 by which he and his followers disowned the authority of Charles II; the privy council replied by ordering every one to abjure this declaration on pain of death. Unlike some of his associates, Renwick refused to join the rising under the earl of Argyll in 1685; and in 1687, when the declarations of indulgence allowed some liberty of worship to the Presbyterians, he and his followers, often called Renwickites, continued to hold meetings in the fields, which were still illegal. A reward was offered for his capture, and early in 1688 he was seized in Edinburgh. Tried and found guilty of disowning the royal authority and other offenses, he refused to apply for a pardon and was hanged on Feb. 17, 1688. Renwick was the last of the covenanting martyrs.

See R. Wedrow, *History of the Sufferings of the Church of Scotland*, vol. iv (Glasgow, 1838); and A. Smolie, *Men of the Covenant* (1904); also Renwick's life by Alexander Shields in the *Biographies Presbyteriana* (1827).

RENWICK, JAMES (1792-1863), educator and engineer,

was born in Liverpool, England on May 30, 1792, of Scottish descent. He emigrated to the United States with his parents in 1794. Two of his sons, Henry Brevoort (1817-1895) and Edward Sabine (q.v.) were also engineers, and his second son, James (q.v.), a distinguished architect. Renwick was graduated from Columbia college in New York city in 1807 and then travelled through Europe with his good friend Washington Irving. Three years later he earned his master's degree from Columbia. In 1812 he taught natural philosophy there during the illness of Prof. John Kemp, serving without pay. He entered government service as topographical engineer with the rank of major and three years later was commissioned colonel of engineers in the state militia. In 1820 he was appointed to the chair of natural philosophy and experimental chemistry at Columbia, which position he held until his retirement in 1853 to become the first emeritus professor of that college. In addition to his regular courses at Columbia, he also lectured on geology, mineralogy, practical mechanics and astronomy. While teaching he was also active in many public engineering projects on which his expert advice was increasingly sought. President Van Buren appointed him in 1838 to the commission of three which tested inventions designed to safeguard steam engine boilers against explosions. Two years later he was a member of the commission appointed to survey the northeast boundary between the United States and New Brunswick; these findings were later incorporated in the Webster-Ashburton treaty. Prof. Renwick was a frequent contributor to the best current periodicals and wrote a number of books on scientific and mechanical problems including *Outlines of Natural Philosophy* (2 vols., 1822-23); *Treatise on the Steam-Engine* (1830); and biographies of David Rittenhouse (1839), Robert Fulton (1845), and Count Rumford (1848) for Sparks's *Library of American Biography*. He also translated from the French, Lallemand's *Treatise on Artillery* (2 vols. 1820) and edited American editions of books on chemistry and mechanics. He died on Jan. 12, 1863.

RENWICK, JAMES (1818-1895), U.S. architect, was born in the section of New York city then known as Bloomingdale, on Nov. 1, 1818, the second son of James Renwick (q.v.) (1792-1863). He was graduated from Columbia college in 1836 at the precocious age of 17, and became an engineer for the Erie railroad. Later, as assistant engineer on the Croton aqueduct, he supervised the construction of a distributing reservoir in what is now the midtown area of Manhattan. His career in architecture began in 1843 when his plans won in the competition for the design and erection of Grace church at Broadway and 10th street. By the time of its completion in 1846, Renwick, still a very young man, had established his reputation as an architect. His early commissions were mainly for churches, including Calvary, St. Stephen's, and St. Bartholomew's. In 1853 the plans he entered in the competition for the designing of the Roman Catholic St. Patrick's cathedral were chosen, and in 1858 the work of more than 20 years was begun. This example of Gothic revival in the heart of the city is now one of its landmarks and occupies the square block bounded by Fifth and Madison avenues, and 50th and 51st streets. In addition to his ecclesiastical designs, Renwick was also architect for many public and private structures, the most outstanding being the Smithsonian Institution and Corcoran gallery in Washington, Vassar college at Poughkeepsie, and numerous hotels, theatres and fashionable residences in New York city and elsewhere. As architect for the Board of Governors of Charities and Correction of New York city, he also built a number of asylums and hospitals. Renwick's early work was mainly Gothic or Romanesque. Later his designs took on a more eclectic character with occasional bad results, but he had imagination and his planning was usually sound. He was a noted connoisseur and acquired a fine collection of paintings and *objets d'art*. He died in New York city on June 23, 1895.

REP, REPP or REPS, cloth made of silk, wool or cotton. The name is said to have been adopted from the French *reps*, a word of unknown origin; it has also been suggested that it is a corruption of "rib." It is woven in fine cords or ribs across the width of the piece. In various forms it is used for dresses, and to some extent for ecclesiastical vestments. In wool and cotton it is also used for upholstery purposes.

REPARATIONS. Reparations are a levy upon defeated nations to compensate the victorious powers in some measure for the costs of war. The word came into general use after 1918 to describe the economic obligations of the Central to the Allied and Associated Powers and was meant to replace the older conception of war indemnities which were exacted as a punitive measure as well as in payment for war losses. The word reparations was used again after World War II to designate part of the payments which the United Nations participating in the war demanded of the defeated countries, mainly Germany, Japan and Italy. The levying and payment of reparations involves ethical and economic considerations of a complex kind, calling for the determination of the exact responsibility of the defeated nations, for appraising their ability to make reparation and estimating the capability of the victorious nations to accept it.

There are two practicable ways in which a defeated country can make reparation. It can pay over in cash or kind a portion of the goods and services it is currently producing; i.e., a part of its national income. Or it can pay over in cash or kind some of its capital in the form of machines, tools, rolling stock, merchant shipping and the like, which is a part of its national wealth. The payment of gold or other universal money is not a practicable method of paying reparations. The supposed consequence of reparations is a decrease in the income, and hence level of living, of the defeated nation, and an increase in the income of the victorious nation, the capitalized value of the increase being equal to its war costs. However, there is no warrant for these suppositions in either the economics of reparations or in historical experience with them. Experience suggests that the smaller the reparations levy the more likely it is to be paid, and conversely that large levies are unlikely to be collected. In both World Wars I and II the failure to obtain desired reparations was unmistakable. Indeed, some of the victorious nations eventually had to make payments to the defeated in the interests of restoring economic and political stability. After both wars the initial policy of the victors was the imposition of severe reparations. Though understandable, this attitude had little justification and gradually changed by force of circumstances to a policy of making the conquered nations self-supporting as quickly as possible.

Magnitude of Reparations.—The size of the defeated nation's liability cannot be determined by the war costs for which it is directly or indirectly responsible. These costs are of two kinds, economic and social. The economic cost of war is the value of civilian goods and services which must be foregone in order that resources can be used for war production, plus the capital destruction resulting from war. The social cost of war is the burden created by loss of life and disorder in social institutions. The loss of life has economic implications, but its cost cannot be measured because the labour value of human life is not capitalized as, say, the income value of equipment can be capitalized. Estimates can be made of the economic costs of war, and they are usually much in excess of the capacity of the defeated nation to make reparation. For example, after World War II the principal belligerents submitted claims of \$320,000,000,000 against Germany. This sum was more than ten times greater than the total prewar national income of Germany (at constant prices) and an even greater multiple of German income at the end of the war.

Since the magnitude of reparations cannot be determined by war costs, it must be determined by the defeated nation's ability to pay, and this is much less than its imputed liability. Its ability to pay is dependent on three factors: (1) its national wealth or alternatively its national income; (2) the ability of either the occupying powers or the government of the defeated nation to organize the economy for the payment of reparations; and (3) the capacity of the victors to organize their economies for the productive use of reparation receipts. The first of these is most important. In the two world wars, the economic resources of all belligerents were destroyed or depleted more rapidly than they could be replaced. Each side destroyed the capital of the other at a great capital cost to itself; and the capital

which escaped destruction was not maintained with the same care devoted to it in peacetime.

The political instability which usually follows a war makes it difficult to organize the defeated economy for the payment of reparations. Authority is diffuse and uncertain; there are conflicts among the victorious nations, and the populace of the defeated country is, to say the least, unco-operative, particularly in the matter of transferring its capital or income to recent enemies. Finally, the payment of reparations depends on the willingness and ability of the victorious countries to accept the new economic structure attendant upon transfers of income or capital. Here occurred the paradoxes of reparations history in the 20th century. Following World War I, some of the Allied Powers were able to conceive of no limit to a justifiable tribute from Germany, but when payments out of income began the Allies found the imports competing with domestically produced goods and services and thereupon took measures which prevented Germany from honouring its obligations. After World War II, the transfers of capital from Germany and Japan so threatened to dislocate the economic structure of Europe and Asia that measures were taken to reduce reparation liabilities; by 1950 payments had virtually ceased.

METHODS OF PAYMENT

The payment of reparations in kind or cash out of income or capital constitutes an export surplus; i.e., the paying nation sends out of the country more goods and services than it imports. Reparations are impossible without this surplus, and it is for practical purposes more dependent on increasing exports than on decreasing imports. The fact that reparations are possible only via an export surplus should not be obscured by the financial mechanics of reparations. The defeated nation usually compensates the private owners of capital for the export of the goods which constitute reparations, and to do this it taxes or borrows from its citizens. But reparations cannot be paid out of revenue raised internally; the revenue must be converted into income or capital for transfer to the victor nation or into the currency of that nation. After World War I, reparations were designed to be paid mainly in cash out of income. After the second war, they were meant to be paid in kind, mainly out of capital.

Payments in Kind.—If payments in kind are made out of capital, the defeated nation pays over to the victors specific assets within the defeated economy and titles to assets held abroad. After 1918, the Allies obtained the largest vessels in the German merchant marine and a small amount of additional capital. After 1945, the United Nations seized merchant vessels and industrial equipment in Germany and Japan, acquired German and Japanese owned assets within the victor countries and sought to obtain axis-owned assets within neutral countries. Most of the owners of this property were compensated by revenue raised within the defeated nations, the effect being to distribute the burden of the loss among enemy nationals whether property owners or not.

Reparations in the form of capital transfers in kind have certain, though limited, advantages. They avoid some of the more complex monetary problems of cash payments. They are adaptable to a general program of economic disarmament whereby victor nations dismantle and remove industrial equipment of actual or potential military value. Some of this equipment may be of immediate peacetime value to the victorious economies, relieving critical shortages and assisting in reconstruction. Against these advantages must be set the complex economic problems created by the transfers. It is difficult if not impossible to distinguish between industrial equipment of military value and that which can be used only to produce peacetime goods. The steel industry may be used for peaceful purposes or it may become the centre of the munitions industry. The war potential of an industry may be reduced by limiting its capacity but this also limits its peaceful uses. An even greater problem is the dislocation of economic structure which capital removals produce. Reducing plant capacity or eliminating it is a complex technical and economic undertaking. A slight error in removing too much

of one kind of equipment can produce a great loss in another industry which in consequence must operate at undercapacity. Even with complete technical consistency in scaling down plant facilities there can be unnecessary losses when the reduced output is measured in monetary (i.e., economic) units. The removal and transportation of capital is expensive, and if any of the labour is done by enemy nationals there is likelihood of additional expense through sabotage. Capital removals require a reallocation of resources in both the defeated and victorious countries. During the process there is a loss of income resulting from installation costs and partial unemployment. Meanwhile the defeated country may become a charge on its conquerors, requiring relief of various kinds until it can become self-supporting. These problems are present in the most ideal circumstances which can be supposed.

In the conditions likely to be present, capital reparations mean a very long-term reduction in income for the victorious nations as well as the defeated. This is probable because capital is removed from an economy where it has been used efficiently with trained labour to one where it must be used less efficiently for a considerable time. The net effect is then a lower income for all countries, victorious as well as defeated. This consequence is avoidable only by the creation of a perfect mechanism for the transfer of capital and by supposing that the recipient nations be able to use it as efficiently as the paying nation. Such conditions are improbable. This being so, reparations are apt to produce quite the opposite of their intended effect. This was the experience after World War II.

Following World War I there was some payment of reparations in kind out of income. There were other instances of this method. Out of its annual production, a paying country exports certain commodities to its creditors or performs certain services for them. It can, for example, ship specified quantities of raw material, fuel or manufactured goods, and it may perform transportation and labour services. It may send numbers of its workers to the victorious nation to restore areas damaged by the war and repatriate them when the work is completed. The difficulties encountered in a scheme of capital reparations are present here also but on a lesser scale. The excessive export of current output may force a reduction in plant operations within the defeated countries. The receipt of these goods and services by the victors disturbs their normal exchange pattern. After World War I, the immigration of German workers into France to restore the devastated areas caused French workers to protest that their wages were being reduced by the increased labour supply. After World War II, some British trade unions resisted the attempt of the Labour government to use German prisoners of war to relieve critical labour shortages. Similarly, some U.S. manufacturers complained that the import of Japanese goods on reparations account was driving down prices in the U.S.

Cash Payments.—Prior to World War II, reparations were more often made as cash payments than as transfers in kind. It was believed that such a method was easier to organize and more productive of a successful settlement (a viewpoint which was reversed after World War II). Cash payments can be made out of accumulated capital, in which case the paying country sells certain of its assets held either at home or abroad, converts the proceeds into the currency of the victorious nation and pays it over to the latter's government. The effect of capital transfers via cash payments need not be quite as disturbing as that of capital transfers in kind, though in practice both may produce much the same result. A conceivable advantage of the former is the greater opportunity given the paying nation to dispose of its capital at a minimum loss; it may sell it on the highest paying market and convert the receipts into the currency of the victor nation, while capital transfers in kind must be made directly to the victor nation and valued realistically at the worth to it.

After World War I, the bulk of reparations levied on Germany were to consist of cash payments out of income over a period of years. The successful execution of this plan called for an export surplus in the paying country and conversion of the surplus into the currency of the receiving nations. The effect was a reduction in the income of the paying nation and an increase

in that of the recipients. Cash payments produce distinctive effects which are not present when reparation is made in kind; they arise because the debtor country must obtain the currency of the creditor nation. The nature and importance of the effects depend on the size of reparations in relation to the national income of the debtor and creditor countries, on the sensitivity of their price levels to expenditures and receipts from imports and exports, on the flexibility of their foreign exchange rates and on the money supply together with the rate at which it is spent. As these factors are highly variable when taken separately or together, it is impossible to generalize precisely about the effect of cash reparations, depending as it does on the magnitude and interrelations of the variables. If any one result is more probable than others, it is a fall in the foreign value of the paying nation's currency and a concomitant rise in that of the receiving country. This in turn increases the real cost of reparations to the debtor and creates a corresponding gain to the creditor. Because its money buys less of the money of the creditor, the debtor must offer a greater quantity of exports in order to obtain a given quantity of the creditor's money. It is to be repeated that this is a probable, not an invariable, consequence.

There are two major conditions for the successful settlement of cash reparations. Payments must be within the defeated nation's ability to pay after full account is taken of their monetary effects, and payments must be acceptable to the receiving country. The latter must either increase its net imports from the paying nation or from a third nation which is in debt to the paying nation. The inherent complexities of a reparations program of any kind usually have been made more troublesome by the imposition of controls over the economies of the defeated and victorious nations. This was significant after World War II when the German and Japanese economies were closely regulated and when there was regulation in every important victorious nation excepting the U.S. Control over prices, the movement of goods and labour represent a comprehensible wish to soften the rigours of reconstruction and of readjustment from war. This, however, does not alter the fact that control removes from the economy the price mechanism whereby gains and losses from alternative lines of action can be compared. This was recognized after 1945 when an effort was made to remove Japanese industrial equipment to nonindustrial nations of Asia and the Pacific. As the Japanese economy was controlled there was no realistic way of appraising the final results of the transfer, nor was there any method of measuring the usefulness of the equipment to the recipient nations because they too controlled their economies. Eventually it was concluded that the transfers had no economic justification.

REPARATIONS AND WORLD WAR I

The history of reparations after 1918 does not disclose any great appreciation of their economic implications, although prior to that reparations were not the complex problem they later became. Indemnities (as the payments were then called) were levied in the Napoleonic, Franco-Prussian and the Russo-Japanese Wars. The amounts were moderate and were paid mainly by the surrender of foreign-held assets and from the proceeds of foreign loans, the transfers being made in a relatively short time.

Germany's Liability.—Following World War I, however, the problem of reparations was never completely solved. Without specifying the exact amount to be paid, the treaty of Versailles held Germany responsible for all damages to civilians and their dependents; for losses caused by the maltreatment of prisoners of war; for pensions to veterans and their dependents; and for the destruction of all nonmilitary property. Following a series of conferences in 1920, Germany's liability was fixed tentatively at a minimum of 3,000,000,000 gold marks annually for 35 yr. with maximum payments not to exceed 269,000,000,000 marks. Germany immediately declared it was unable to pay even the minimum, and there followed successive reductions culminating in the decision of the London conference of 1921, which fixed the liability at 132,000,000,000 (all figures in gold marks) to be

paid in annuities, or annual instalments, of 2,000,000,000 marks plus an amount equal to 26% of Germany's annual exports. Germany's default brought the occupation of the Ruhr in 1923 by French and Belgian troops in order to collect reparations by force. Dispossessed of this important area, Germany was unable to make payments and each attempt to convert marks into foreign currency drove down their value. The result was the disastrous inflation of 1923 when the mark fell to a billionth of its par value.

In 1924 the Allies sponsored the Dawes plan which stabilized the nation's internal finances by a reorganization of the Reichsbank; a transfer committee was created to supervise reparations payments. The total liability was left to later determination, but standard annuities of 2,500,000,000 marks were set subject to increase. The plan was initiated by a loan of 800,000 marks to Germany. The Dawes plan worked so well that by 1929 it was believed that the stringent controls over Germany could be removed and total reparations fixed. This was done by the Young plan, which set reparations at 121,000,000,000 marks to be paid in 59 annuities. But hardly had the Young plan started operation than the world depression of the 1930s began and Germany's ability to pay dwindled to the vanishing point. In 1932 the Lausanne conference proposed to reduce reparations to the token sum of 3,000,000,000 marks, but the proposal was never ratified. Adolf Hitler came to power in 1933, and within a few years all important obligations under the treaty—political as well as economic—were repudiated.

Obstacles to Settlement.—Two circumstances were mainly responsible for the failure of reparations. One was the political instability of Germany and its refusal to accept responsibility for the war. A more fundamental circumstance was the unwillingness of the creditor nations to accept repayment payments in the only practicable way they could be made—by the transfer of goods and services. The attitude of the creditors had its origin in the notion that a nation is injured by importing more than it exports. Through the 1920s the creditor nations tried to exclude Germany from world trade and simultaneously to increase their exports to Germany (on credit, of course). By the logic of its position Germany was committed to failure.

Germany's Actual Payments.—The total of reparations paid is not exactly known because of uncertainty over payments between 1918 and 1924, their probable value being, however, 25,000,000,000 marks. From 1924 to 1931 Germany paid 11,100,000,000 marks, making total payments about 36,100,000,000 marks. During the postwar period, however, Germany borrowed 33,000,000,000 marks from abroad; its net payments to the rest of the world were therefore 3,100,000,000 marks. The reparations program was most successful during the period of greatest borrowing, between 1924-31, when Germany paid 11,100,000,000 marks on reparations account and borrowed 18,000,000,000 marks, the net transfer being 6,000,000,000 marks to Germany. Although reparations often were called the cause of Germany's postwar difficulties, their direct effects were actually negligible. The following table shows that reparations were never a sizable portion of any important economic magnitude.

German Reparations, 1924-30
(in millions of marks)

	1924	1925	1926	1927	1928	1929	1930
Reparations payments	1,000	1,720	1,500	1,584	1,990	2,501	1,253
National income . . .	40,000	55,000	50,000	67,500	65,000	65,050	54,600
Governmental expenditures . . .	3,725	4,450	4,828	5,917	6,300	7,475	7,753
Exports	6,552	9,300	10,414	10,801	12,276	13,483	12,300
Reparations as a percentage of national income	2.5	3.1	3.0	2.3	3.1	3.8	2.3
Reparations as a percentage of governmental expenditures . . .	26.8	39.1	31.1	26.9	31.6	32.1	17.5
Reparations as a percentage of exports . . .	15.4	18.5	14.4	14.6	16.3	18.3	10.1

REPARATIONS AND WORLD WAR II

Reparations for the second war were viewed in two distinct ways. In one they were made incidental to a program of economic

disarmament and were to be paid out of capital of: (1) actual or potential military value; and (2) that in excess of the amount permitted the defeated nations by the victorious powers. In the other view, reparations were regarded in the conventional way as payments in compensation for the costs of war and were to be made in kind out of capital and income. These two views were both enunciated in the policy laid down by the major Allies in conferences at Yalta and Potsdam in 1945.

The two conceptions are not wholly consistent, and the attempt to apply both of them created confusion and conflict. Removals of capital reduce the economic power of the defeated nation but they do not necessarily increase the power of the recipient nation correspondingly, so that the loss of income by the defeated nation may be (and usually is) greater than the gain to the victors. With each removal of capital, the ability to pay and receive reparations is lessened. If, on the other hand, maximum reparations are wanted by the victorious nations they cannot disarm the defeated nation of its economic power. These difficulties of the Allied reparations program were later complicated by two additional factors: the disagreement between the U.S.S.R. and U.S., which prevented the conclusion of peace treaties with the major defeated nations; and the establishment by the U.S. of the Economic Cooperation Administration (ECA) for the purpose of capital reconstruction and development in Europe and Asia.

German Reparations.—The express policy was formulated at Potsdam in 1945. Uniform control was to be established over the entire German economy and administered jointly by four powers in their zones of occupation. The purpose was to dismantle German industry in order that the nation never again could engage in war. Dismantlement was to be limited by two considerations: the German level of living was not to be less than the average living level of other European countries excepting Britain and Russia; and Germany was to be left with sufficient capital in order to pay for its essential imports and so be self-supporting. Reparations were to be paid out of the difference between total German capital and the permissible amount. The distribution of reparations was to be made by the Inter-Allied Reparations Agency established in 1945. A "level of industry" plan was formulated to specify the kind and amount of reparations available to claimant nations. It soon was recognized that the initial claims of \$320,000,000,000 could not be satisfied, and the Allies announced their satisfaction with reparations which would "compensate in some measure for the loss and suffering caused by Germany."

Shortly after the end of the war, the political disagreement between eastern and western Allies made unified control impossible over the German economy. Its division into eastern and western areas curtailed the useful exchange of agricultural for industrial products and removed the possibility of Germany's supporting itself. The division also increased the difficulties of capital removals since there was no way of appraising their effect on the total economy. The western powers sought to unify control over their zones in order to advance the reparations program, but here too there was disagreement over the amount of capital to be removed, France insisting on maximum removals in order to disarm Germany completely and Britain and the United States maintaining that Germany should be allowed enough industrial power to assist in the recovery of the entire economy of western Europe. In 1947 the U.S. offered large loans to European countries if they in turn would co-operate by increasing their output and by reducing trade barriers. The conditions were accepted and the ECA (originally called the Marshall plan) was begun. It was quickly discovered that European reconstruction would be assisted by allowing the Germans to retain the capital in their western areas (no assistance was given to the eastern area). There was then a conflict between the program for reparations and that for reconstruction. This was resolved by reducing reparations to a token amount, and by 1950 payments had virtually ceased. Moreover, the economy of western Germany had so increased in importance that the Allies by this time were extending loans to Germany for reconstruction. In the eastern zone, the Russians found that capital removals did

not yield the expected value. They were halted, and reparations in kind were collected out of income.

The net effect of German reparations could not be determined because reliable information was lacking. It was known that the value of capital removals was much less than expected and the costs of occupation (not including ECA loans) higher than anticipated. The U.S.S.R. and Poland together obtained approximately 25% of the arable land of Germany by transfers of territory; the former in 1945-46 took approximately \$500,000,000 of German income, a part of which was to go to Poland. It is probable that after World War II the total of reparations paid by Germany was negative, that payments to Germany by victor nations exceeded receipts from Germany. Reparation payments from other European nations could not be estimated, again because reliable information was wanting. Italy was required to pay the U.S.S.R. \$100,000,000 in kind out of capital and income; against this must be set a considerably larger though unknown sum representing relief payments to Italy by western powers.

Japanese Reparations.—The initial policy was identical with that for Germany and the consequences quite similar. Japan was to be disarmed of its economic power but left with enough capital to become self-supporting and to maintain a living level equal to that of other Asiatic countries. Reparations were to consist of capital in excess of the permissible amount. To this end an inventory of surplus capital was taken in 1945 and large-scale removals were planned. The Pauley report embodying the program was challenged and its conclusions were later modified, reducing Japan's liability. The major recipients were to be Asiatic countries which Japan had occupied during the war.

As in Germany, the collection of reparations was more expensive than expected and their value to the recipients less than expected. The claimant nations were unable to agree on their proper shares, which delayed execution of the program. Meanwhile, reparations capital in Japan was allowed to deteriorate, and Japan continued as a deficit economy supported mainly by the U.S. as the major occupying power. The continued deficit caused the U.S. to suspend all reparations deliveries in May 1949. To that date, total reparations paid out of assets held within Japan were 153,000,000 yen or \$39,000,000 (at 1939 values). In addition, an unspecified sum was paid out of Japanese assets held in foreign countries. Offsetting total receipts from reparations was a considerably larger sum representing relief and occupation costs of the victor nations. As in Germany, occupation costs in Japan were not allocated as reparations receipts were. Some nations therefore obtained net reparations. Taken together, however, Allied reparations from Japan were also negative; net payments were made to Japan as well as to Germany. That these payments might have been still larger had no reparations whatever been collected is a moot question; it is to be noted that some of the payments were necessitated by the reparations program itself.

REPEAL, the abrogation, revocation or annulling of a law. The word is particularly used in English history of the movement led by Daniel O'Connell (q.v.) for the repeal of the act of Union and in the United States for the repeal of the 18th (Prohibition) amendment of the constitution.

REPERTORY THEATRE: see **DRAMA**.

REPHAIM (Heb. shades, ghosts), a race of reputed giants mentioned in the Bible as the prehistoric inhabitants of Canaan before the land was conquered by the Israelites. Rephaim are often held to be inclusive of the other Biblical giants, namely the Emim, Zuzim, Anakim and Horim. The giant legend, as well as that of longevity, is common in ethnic myths which tend to ascribe extraordinary powers and qualities to extinct forbears. The concept of larger than human proportions is also held to

have arisen from the sight of ancient ruins and tombs. For example, the sarcophagus of Og, the king of "Bashan which was called the land of the giants" (Deut. 3:11) is described as being giant sized. In the later books of the Bible (Psalms 88:11; Job 26:5, etc.) Rephaim is the Hebrew word used to denote the shades of the dead which dwell in Sheol, similar to the ghosts (*gigim, gidim*) of Sumerian mythology. The valley of the Rephaim was a plain in Judah where David twice conquered the Philistines (II Sam. 5:17-25).

REPIN, ILYA YEFIMOVICH (1844-1930), Russian painter, was born in 1844 at Chuguyev in the department of Kharkov, the son of parents in straitened circumstances. He learned the rudiments of art under a painter of saints named Bunakov, for three years gaining his living at this humble craft. In 1863 he obtained a studentship at the Academy of Fine Arts of St. Petersburg (Leningrad), where he remained for six years, winning the gold medal and a travelling scholarship which enabled him to visit France and Italy. He returned to Russia after a short absence, and devoted himself exclusively to subjects having strong national characteristics. In 1894 he became professor of historical painting at the St. Petersburg academy. Repin's paintings are powerfully drawn, with not a little imagination and with strong dramatic force and characterization. He died at Kuokkala in Finland on Sept. 29, 1930.

His chief pictures are "Procession in the Government of Kiev," "The Arrest," "Ivan the Terrible's murder of his Son," and, best known, "The Reply of the Cossacks to Sultan Mahmoud IV."

REPPINGTON, CHARLES A'COURT (1858-1925), British military critic, was born on Jan. 29, 1858, and commissioned in the Rifle Brigade in 1878. After serving with distinction in the Afghan War, the Sudan and South Africa, he was appointed military attaché at Brussels and The Hague in 1900, being then a lieutenant colonel. Two years later his military career ended abruptly through domestic causes, and he took up journalism, becoming military correspondent of the *Times* in 1904. In 1915, after staying with the British commander-in-chief in France, he came home to call attention to the shell shortage. In Jan. 1918 a divergence of views caused him to leave the *Times* for the *Morning Post*, and after World War I he became military correspondent of the *Daily Telegraph*, a post which he held till his death at Hove, Sussex, on May 25, 1925.

His works include *Vestigia* (1919); *The First World War, 1914-18: Personal Experiences* (1920); *After the War: A Diary* (1922); *Policy and Arms* (1924).

REPPINGTON (or **REPPYNGTON**), **PHILIP** (d. 1424), English bishop and cardinal, was educated at Oxford and became an Augustinian canon at Leicester before 1382. A man of some learning, he came to the front as a defender of the doctrines taught by John Wycliffe; for this he was suspended and afterwards excommunicated, but in a short time he was pardoned and restored by Archbishop William Courtenay, and he appears to have completely abandoned his unorthodox opinions. In 1394 he was made abbot of St. Mary de Pré at Leicester, and after the accession of Henry IV to the throne in 1399 he became chaplain and confessor to this king, being described as "clericus specialissimus domini regis Henrici." In 1404 he was chosen bishop of Lincoln, and in 1408 Pope Gregory XII made him a cardinal. He resigned his bishopric in 1419. Some of Repington's sermons are in manuscript at Oxford and at Cambridge.

REPLEVIN, a term in English law signifying the recovery by a person of goods unlawfully taken out of his possession by means of a special form of legal process; this falls into two divisions—(1) the "replevy," the steps which the owner takes to secure the physical possession of the goods, by giving security for prosecuting the action and for the return of the goods if the case goes against him, and (2) the "action of replevin" itself. The jurisdiction in the first case is in the county court (q.v.); in the second case the supreme court has also jurisdiction in certain circumstances. At common law, the ordinary action for the recovery of goods wrongfully taken would be one of detinue (q.v.); but no means of immediate recovery was possible till the action was tried, and until the Common Law Procedure Act 1854 the defendant

might exercise an option of paying damages instead of restoring the actual goods.

United States.—In the United States the action of replevin is almost entirely regulated by statute in each jurisdiction, and is materially different from the use and construction of the common law action of replevin in England. The action is laid upon a wrongful taking and a wrongful detaining or a wrongful detaining alone. It is a proceeding *in rem* to recover goods and chattels, *i.e.*, every kind of personal property to which the plaintiff has the right to present possession, and also, by statute, a proceeding *in personam*, to recover damages for either the detention or both the caption and detention, according to the wording of the statute. It is a possessory action, the gist of which is the right of possession in the plaintiff, but in nearly all cases the title is determined since the owner is entitled to possession, and possession by verdict where the title is in question awards title. It will not lie to recover real property or fixtures attached to the freehold, nor can it be maintained in any case in which the object sought is the determination of title to land. In some jurisdictions all damages growing out of the wrongful taking and detention may be assessed in the replevin action; in others, where the statute limits the recovery of damages to detention only, a separate subsequent action may be brought to recover compensatory and punitive damages sustained by a malicious wrongful taking (*Crockett v. Miller*, 112 Federal 729; *Perrie v. Warden-Justice Motors*, Sup. Ct. D. C. No. 71,338). This is a rule peculiar to replevin, where so regulated by statute, and is at variance with the general rule of law requiring the adjudication in one cause of action of all claims and demands growing out of a single tort.

REPININ, ANIKITA IVANOVICH, PRINCE (1668-1726), Russian general, and one of the collaborators of Peter the Great. He took part in all the principal engagements of the Great Northern War. Defeated by Charles XII. at Holowczyn, he was degraded to the ranks, but was pardoned as a reward for his valour at Lysena and recovered all his lost dignities. At Poltava he commanded the centre. From the Ukraine he was transferred to the Baltic Provinces and was made the first governor-general of Riga after its capture in 1710. In 1724 he succeeded the temporarily disgraced favourite, Menshikov, as war minister. Catherine I. created him a field-marshal.

See A. Bauman, *Russian Statesmen of the Olden Time* (Rus.), vol. I. (St. Petersburg, 1877).

REPININ, NIKOLAI VASILIEVICH, PRINCE (1734-1801), Russian statesman and general, grandson of the preceding, served during the Rhenish campaign of 1748 and subsequently studied in Germany. Peter III. sent him as ambassador in 1763 to Berlin. The same year Catherine transferred him to Warsaw, with instructions to form a Russian party in Poland from among the dissidents, who were to receive equal rights with the Catholics. Repinin convinced himself that the dissidents were too poor and insignificant to be of any real support to Russia, and that the whole agitation in their favour was factitious. At last, indeed, the dissidents themselves even petitioned the empress to leave them alone. The attempt had failed, and Repinin went to fight the Turks. At the head of an independent command in Moldavia and Wallachia, he prevented a large Turkish army from crossing the Pruth (1770); distinguished himself at the actions of Larga and Kagula; and captured Izmajil and Kilia. In 1771 he received the supreme command in Wallachia and routed the Turks at Bucharest. A quarrel with the commander-in-chief, Rumyantsev, then induced him to send in his resignation, but in 1774 he participated in the capture of Silistria and in the negotiations which led to the peace of Kuchuk-Kainarji. In 1775-76 he was ambassador at the Porte. On the outbreak of the war of the Bavarian Succession he led 30,000 men to Breslau, and at the subsequent congress of Teschen, where he was Russian plenipotentiary, opposed Austria to make peace with Prussia. During the second Turkish war (1787-92) Repinin was, after Suvarov, the most successful of the Russian commanders. He defeated the Turks at Salcha, captured the whole camp of the *seraskier*, Hassan Pasha, shut him up in Izmajil, and was preparing to reduce the place when he was forbidden to do so by Potemkin (1789).

On the retirement of Potemkin (*q.v.*) in 1791, Repinin succeeded him as commander-in-chief, and immediately routed the grand vizier at Machin, a victory which compelled the Turks to accept the truce of Galatz (July 31, 1791). In 1794 he was made governor-general of the newly acquired Lithuanian provinces. The emperor Paul raised him to the rank of field-marshal (1796), and, in 1798, sent him on a diplomatic mission to Berlin and Vienna in order to detach Prussia from France and unite both Austria and Prussia against the Jacobins. He was unsuccessful, and on his return was dismissed from the service.

See A. Kraushar, *Prince Repinin in Poland, 1764-8* (Pol.) (Warsaw, 1900); "Correspondence with Frederick the Great and others" (Rus. and Fr.), in *Russky Arkhiv* (1865, 1869, 1874, Petersburg); M. Longinov, *True Anecdotes of Prince Repinin* (Rus.) (St. Petersburg, 1865).

REPORTING, the business of reproducing, mainly for newspapers, but also for such publications as the *Parliamentary or Law Reports*, the words of speeches, or of describing the events in contemporary history by means of the notes made by persons known generally as reporters. There was no systematic reporting until the beginning of the 19th century, though there was parliamentary reporting of a kind almost from the time when parliaments began, just as law reporting (which goes back to 1292) began in the form of notes taken by lawyers of discussions in court. The first attempts at parliamentary reporting, in the sense of seeking to make known to the public what was done and said in parliament, were made by the *Gentleman's Magazine* in 1736. Access to the houses of parliament was obtained by Edward Cave (*q.v.*), the publisher of this magazine, and some of his friends, and they took surreptitiously what notes they could. These were subsequently put into shape for publication by another hand. Such reporting was a violation of the standing order of the House, passed in 1718, declaring the publication of any of its proceedings to be a breach of privilege, and on the attention of the House being called in 1738 to the reports in the *Gentleman's Magazine* it threatened to proceed with the utmost severity against the offenders. Thereupon Cave published his reports as "Debates in the Senate of Lilliput," and instead of giving the first and last letters of each speaker's name, employed such barbaric terms as "Wingul Pulnub" for William Pulteney. Dr. Johnson composed the speeches for the *Gentleman's Magazine* from 1740 to 1743, the names of the speakers being given in full. Though he said he took care not to let the "Whig dogs" get the best of it, he really dealt out argument and eloquence with equal hand to both political parties.

In the latter half of the century the newspapers began to report parliamentary debates more fully, with the result that, in 1771, several printers, including those of the *Morning Chronicle* and the *London Evening Post*, were ordered into custody for publishing debates of the House of Commons. A long and bitter struggle between the House and the public ensued. John Wilkes took part in it. The lord mayor of London and an alderman were sent to the Tower for refusing to recognize the Speaker's warrant for the arrest of certain printers of parliamentary reports. But the House of Commons was beaten. In 1772 the newspapers published the reports as usual, and their right to do so has never since been really questioned. Early in the 19th century, greater freedom of access to both Houses was given to newspaper reporters. By the middle of the century special galleries for their accommodation were provided in the legislative chambers of the new palace of Westminster erected in place of the old which was burned down in 1834. The press gallery of the House of Lords was first used in 1847, and the press gallery of the House of Commons in 1852. At this time the London newspapers had a monopoly of parliamentary reporting. Only their representatives were admitted to the galleries, which secured them this virtual monopoly.

The *Times* established a supremacy for the best parliamentary report, which has never been shaken. The other London papers, however, gave less and less attention to the debates while at the same time the public throughout the country wanted to know more fully what their representatives were saying in parliament. Gradually the leading provincial newspapers adopted the

practice of employing reporters in the service of the London journals to report debates on subjects of special interest in localities; and these reports, forwarded by train or by post, were printed in full, but of course a day late. The London papers paid little attention to debates of local interest, and thus the provincial papers had parliamentary reporting which was not to be found elsewhere. Bit by bit this feature was developed. It was greatly accelerated by the arrangement of placing telegraphic wires from London at the disposal of provincial newspapers—of course on payment of a large subscription—from six o'clock at night till three o'clock in the morning. This was the beginning of the "special wire" which now plays so important a part in the production of almost all newspapers. The arrangement was first made by the *Scotsman* and by other newspapers in Scotland in the 'sixties. The special wires were used to their utmost capacity to convey reports of the speeches of leading statesmen and politicians; and, instead of bare summaries of what had been done, the newspapers contained pretty full reports. When the telegraphs were taken over by the State in 1870 the facilities for reporting were increased in every direction. News agencies undertook to supply the provincial papers. These agencies were admitted to the reporters' galleries in the houses of parliament, but the reports which any agency supplied were identical; that is to say, all the newspapers taking a particular class of report had exactly the same material supplied to them—the reporter producing the number of copies required by means of manifold copying paper. Accordingly attempts were made by leading provincial newspapers to get separate reports by engaging the services of some of the reporters employed by the London papers. The "gallery" continued to be shut to all save the London papers and the news agencies. The *Scotsman* sought in vain to break through this exclusiveness. The line, it was said, must be drawn somewhere, and the proper place to draw it was at the London press. But in 1880 a select committee of the House of Commons was appointed to consider the question. It took evidence, and it reported in favour of the extension of the gallery and of the admission of provincial papers. The press gallery of the House of Commons was accordingly enlarged and representatives of the leading provincial newspapers were admitted at the opening of the session of 1881.

What is commonly called "descriptive reporting" has in some cases nearly shouldered the reporting of speeches out of newspapers. The special correspondent or the war correspondent is a "descriptive reporter." The "interviewer" came into great prominence during the 'eighties and 'nineties. The variety of work open to reporting causes considerable difference, of course, in the professional status of the journalists who do such work. This subject generally is discussed in the article *NEWSPAPERS*, but one instance of the recognition of the modern reporter's responsibility is worth special mention. In the year 1900, in the English case of *Walter v. Lane* it was decided, on the final appeal to the House of Lords, that the reporter of a speech, printed verbatim in a newspaper, was under the Copyright Act of 1842 to be considered the "author." Absurd as it might seem to call the reporter the author of another man's speech, the decision gave effect to the fact that it is his labour and skill which bring into existence the "copy" to which alone can right of property attach. Strictly speaking, he is the author of the *report* of the speech; but for literary purposes the report is the speech. It must, however, be borne in mind that there may be more than one verbatim report, and therefore more than one "author." See also *COPYRIGHT; NEWSPAPERS; SHORTHAND; PRESS LAWS; TELEGRAPH.*

(X.; M. MACD.)

UNITED STATES

The system of newspaper reporting developed in America responds to a code of ethics which, although unwritten and without centralized machinery to enforce it, is, nevertheless, a potent influence throughout journalism. These governing rules naturally arise from newspaper experience and legends, and increasingly take concrete form, somewhat by reason of the fact that by 1939 there were 32 "class A" schools of journalism in the United States, and more than 700 other schools or departments, mostly in estab-

lished colleges or universities. It may in general be said that the reporter, whether instructed as a "cub" in the newspaper office or as a student in a professional school, learns that the newspaper, while privately owned and published for profit, is in fact quasi-public in that it possesses a constitutional guarantee of freedom and owes to society commensurate responsibility to ventilate news which concerns public welfare. News is variously described, but it is generally held to be written record of any event of public interest, reported either on evidential authority of the writer or authenticated by a credited witness. It is assumed that the newspaper may freely publish any news which may be discussed in decent society, which is true, which is not forbidden by law and which serves the public interest. This, of course, means that the reporter must use his powers to ascertain the truth and state it fairly in his report, guard against injustice or harm to individuals or institutions written about, avoid promotion of any private interest, keep confidences that are imparted to him, refuse to serve partisanship by exaggerating the favourable and suppressing the unfavourable factors in news columns and in every way write as considerately and fairly of strangers or antagonists as of protagonists and acquaintances. The reporter is called upon to keep faith both with those concerning whom he writes and those who buy and read his accounts. The publication of the news writers' opinion should be prohibited, the editorial page and personalized columns expressing views, as distinguished from news. The aim is to avoid trespass upon private rights or feelings, except when such course is dictated by certain knowledge that the ends of justice or the welfare of the social order demand such action. A newspaper may not publish advertising in its news columns, without designation. The reporter and his newspaper are called upon by custom to make proper, full and free correction of errors previously made in print. These, sketchily, are the canons of American journalism. The nearest approach to a written code which has general acceptance is that of the American Society of Newspaper Editors, composed of the editors of many of the country's leading newspapers.

Organization.—The organization of the average American newspaper's editorial department is as follows: editor-in-chief, directing policy; managing editor, in control of the writing staff and the composing room; chief editorial writer, conducting the editorial page; city editor, controlling the local staff of reporters, photographers and, perhaps, artists; head of copy-desk, directing the actual preparation of the news as it will appear in print; rewriters, graduate reporters held in the office to write the news that reporters transmit by telephone or rewrite their reports to meet the exigencies of the edition; foreman of the composing-room, responsible to the managing editor or editor-in-chief for the setting of type and delivery of forms of type to the stereotype and press rooms; telegraph editor, responsible for the editing of news which comes by wire, product of the press associations and services and the newspaper's special out-of-town correspondents. Such departments as sports, financial, commodity markets, woman's page, religion, humour and the Sunday edition, if any, are conducted by editors appointed by the managing editor or the editor-in-chief. The three great sources of information are (1) material written by the local staff; (2) news coming by wire; (3) feature material from syndicates, of which in 1939 there were approximately 340 in the United States competing for newspaper patronage. In New York and Chicago local newspapers have established co-operative news organizations through which the routine reports of courts, police headquarters, city hall and such public offices are supplied by a single reporter for all newspapers, although all important events are covered by staff reporters assigned by city editors.

The rank and file of reporters are young men, or occasionally women, who have received public school and college education, perhaps 15 or 20% of them having matriculated in journalism. Those who are talented as fact-finders and as writers usually receive quick promotion, such recognition giving them higher salaries than is usually paid to young people in the professions or the fields of finance, commerce or education. Reporting, in the matter of compensation, ranks with the arts and while true genius

reaps a quick and ample reward mediocre talent is only fairly paid and the mere drudgery of reporting is as poorly paid as clerkships or common labour.

(M. E. P.; X.)

REPOUSSE (Fr. "driven back"), the art of raising designs upon metal by hammering from the back, while the "ground" is left relatively untouched. The term is often loosely used, being applied indifferently to "embossing." Embossing is also called *repoussé sur coquille* and *estampage*, but the latter consists of embossing by mechanical means and is therefore not to be considered as an art process. Moreover, it reverses the method of repoussé, the work being done from the front, and by driving down the ground leaving the design in relief.

Repoussé—a term of relatively recent adoption, employed to differentiate the process from embossing—has been known from remote antiquity. Nothing has ever excelled, and little has ever approached, the perfection of the bronzes of Siris (4th century B.C., in the British Museum), of which the armour-plate—especially the shoulder-pieces—presents heroic figure-groups beaten up from behind with punches from the flat plate until the heads and other portions are wholly detached—that is to say, in high relief from the ground of which they form a part. Yet the metal, almost as thin as paper, is practically of constant thickness, and nowhere is there any sign of puncture.

The art was not only Greek and Graeco-Roman in its early practice; it was pursued also by the Assyrians, the Phoenicians, and other oriental peoples, as well as in Cyprus and elsewhere, and was carried forward, almost without a break, although with much depreciation of style and execution, into mediæval times. In the 11th century the emperor Henry II, presented as a thank-offering to the Basilic cathedral the altar-piece, in the Byzantine style, decorated with fine repoussé panels of gold (representing Jesus Christ with two angels and two saints), which is now in the Cluny Museum in Paris. Up to this time, also, repoussé instead of casting in metal was practised for large work, and Limoges became a centre for the manufacture and exportation of sepulchral figures in repoussé bronze. These were affixed to wooden cores. By the time of Benvenuto Cellini the art was confined almost entirely to goldsmiths and silversmiths (who, except Cellini himself, rarely cast their work); and to them the sculptors and artists of to-day are still content to relegate it.

The elementary principle of the method, after the due preparation and annealing of the plate, was to trace on the back of it the design to be beaten up, and to place it face downwards upon a stiff yet not entirely unresisting ground (in the primitive stage of development this was wood), and then with hammers and punches to beat up the design into relief. According to Cellini, his master Caradosso da Milano would beat up his plate on a metal casting obtained from a pattern he had previously modelled in wax; but he is not sufficiently explicit to enable us to judge whether this casting was a hollow mould, which would result in true repoussé, or in the round, which is tantamount to *repoussé sur coquille*, or embossing.

Nowadays the plate is laid upon and affixed to a "pitchblock," a resinous ground docile to heat, usually composed of pitch mixed with pounded fire-brick, or for coarser work such as brass, with white sand, with a little tallow and resin. This compound, while being sufficiently hard, is elastic, solid, adhesive and easy to apply and remove. Gold and silver are not only the densest and most workable but the most ductile metals, admitting of great expansion without cracking if properly annealed. The tools include hammers, punches (in numerous shapes for tracing, raising, grounding, chasing and texturing the surfaces), together with a special anvil called in French a *recingle* or *ressing*, in English "snarl." The *recingle*, or small anvil with projecting upturned point, was known in the 16th century. This point is introduced into the hollow of the vase or other vessel such as punch and hammer cannot freely enter, which it is desired to ornament with reliefs. A blow of a hammer on that part of the anvil where the prolongation first projects from it, produces, by the return spring, a corresponding blow at the point which the operator desires to apply within the vase. The same effect is produced by the modern "snarl" or "snarl-iron"—a bar of steel, with an inch or two of

the smaller end upturned and ending in a knob—held firmly in a tightly screwed-up vice, whereby the blow is similarly repeated or echoed by vibration. The repoussé work, when complete, is afterwards finished at the front and chased up. (See also EMBOSSEING; BRONZE AND BRASS ORNAMENTAL WORK; SILVERSMITHS' AND GOLDSMITHS' WORK.) (M. H. S.)

REPRESENTATION, a concept with the broad general connotation of making present something or somebody that is not present; but more especially the term is used in a political meaning and pertains to modern government as a method of solving the problem of how to enable a very large number of people to participate in the shaping of legislation and governmental policy.

Representation in the broadest sense has roots which link it with the world of beliefs called magic, a world in which mysterious connections were regularly assumed to prevail between distinct persons and beings, both natural and supernatural. Without going into the historical evolution of the various meanings of "represent," "representation" and "representative," it is worth noting that the modern governmental meaning was not attached to these expressions until the 16th century, when the modern parliamentary development began. Sir Thomas Smith, in his *De Republica Anglorum* (1583), uses the expression freely in describing parliamentary institutions.

It must be admitted, however, that a magical element remained in spite of the continuous effort to rationalize the relationship spoken of as representation. Some writers, like Jean Jacques Rousseau, simply denied that representation of the will of the people is possible. While few would be willing to follow Rousseau, it is generally agreed that representation of the electorate in modern representative assemblies poses very real problems, because the views both of the representative and of those represented are likely to undergo change as the situation changes.

Theoretical Problems of Representation.—In large modern countries the people cannot, of course, assemble in the market place as they did in Athens or Rome. If, therefore, the people are to participate in government, they must select and elect a small number from among themselves to represent them and act for them. Through the course of a long historical evolution, the methods for such elections have been rationalized. The extended struggle over electoral reform in England was fought over this issue; rotten boroughs, patrons and other features of aristocratic nepotism were eliminated. In these reforms, Jeremy Bentham's rational principle of utility prevailed against Edmund Burke's earlier defense of traditional practices. Direct general elections are accepted as the most rational method for choosing representatives, whether they be legislative or executive. For executives are also representatives of the people. The view that this is not so is a survival of attitudes developed during the monarchical age, when progressive forces fought the crown as unrepresentative. It is important that executives be included among the people's representatives because of the paramount role the executive establishment plays in modern government. Public policy in most modern democratic governments is shaped as much by the executive as by the legislature. Some of the most important decisions are made by the executive. The reason for this is that all representation involves ideas; for only through an idea can the making present of one thing or person by another be conceived.

The deepest and most obscure aspect of representation is its ideological foundation. It has always been in controversy between those who would have the representatives of the people act as delegates carrying out instructions and those who would have them be free agents acting in accordance with their best ability and

understanding. The latter alternative was stated by Edmund Burke in his celebrated speech to the electors at Bristol:

My worthy colleague [Burke's opponent for the seat] says his will ought to be subservient to yours. If that be all, the thing is innocent. If government were a matter of will upon any side, yours, without question, ought to be superior. But government and legislation are matters of reason and judgment, and not of inclination; and what sort of reason is that, in which the determination precedes the discussion; in which one set of men deliberate and another decide . . . ? To deliver an opinion is the right of all men; that of constituents is a weighty and respectable opinion, which a representative ought always to rejoice to hear; and which he ought always most seriously to consider. But *authoritative* instructions; *mandates* issued, which the member is bound blindly and explicitly to obey, to vote and to argue for, though contrary to the clearest conviction of his judgment and conscience; these are things utterly unknown to the laws of this land, and which arise from a fundamental mistake of the whole order and tenor of our constitution. Parliament is not a congress of ambassadors from different and hostile interests, which interests each must maintain, as an agent and advocate, against other agents and advocates; but, Parliament is a *deliberative* assembly of *one nation*, with *one interest*, that of the whole; where not local purposes, not local prejudices ought to guide, but the general good . . .

Pushing the matter one step farther, Burke also stated:

Certainly, gentlemen, it ought to be the happiness and glory of a representative to live in the strictest union, the closest correspondence, and the most unreserved communication with his constituents. Their wishes ought to have great weight with him; their opinion high respect; their business unremitting attention . . . But his unbiased opinion, his mature judgment, his enlightened conscience, he ought not to sacrifice to you, to any man, or to any set of men living. These he does not derive from your pleasure; no, nor from the law and the constitution. They are a trust from Providence, for the abuse of which he is deeply answerable.

Burke's idealistic conception accords neither with the reality of popular politics nor yet with the democratic ideal that the will of the people should prevail. The issue as to whose will is to prevail and is therefore to be taken as the will of the whole cannot be sidestepped by asserting, as Burke does, that parliament represents *one nation*, with *one interest*. While this is true in the abstract, the issue at hand is who is to say what that general interest is at a given time. For the conflict of various interests and their possible relation to a more comprehensive public interest is the real issue. Abstractly considered, a special mandate cannot be admitted, since it would make the members of representative assemblies into mandataries for special interests. But there is a great difference between a special mandate and a broad indication as to the general line of policy to be pursued.

It is possible to study the representativeness of representative assemblies in terms of the votes as they correlate with the known desires and views of the electorate. In 1928 Stuart Rice made an interesting investigation along these lines in the United States. He correlated the progressiveness of Minnesota legislators with the progressiveness of their districts. The result of his study showed, as might be expected, that there was a correlation, although "the coefficient of correlation was no higher than could be reasonably expected." Similar results were obtained when Rice inquired into the common assumption that men elect as representatives men "of their own kind." Using nationality as a factor, Rice found that Minnesota and Wisconsin legislators, more than two of whom were foreign-born, were favoured by those of their own nationality and that there existed "a well-marked disposition on the part of foreign-born voters to elect men of their own nationality." (Stuart Rice, *Quantitative Methods in Politics*, Appleton-Century-Crofts, Inc., 1928.) As a result of opinion polls, rich materials exist for further detailed correlation between the opinions and behaviour of representatives and those they represent. Perhaps further study will show that the preoccupations and prejudices of the voters themselves convert the representative into a delegate.

The reason that the elected representatives of a party can be said to represent their electorate is basically that these representatives and those whom they represent are bound together by a world of ideas and beliefs which they share. Consequently, it can be assumed that any conclusion the representatives come to with regard to a new issue is likely to be the same as the conclusion the electorate would have come to had it been able to consider the new facts. But we get lost in metaphysics of a rather shady sort when

we claim that the majority represents the minority in any concrete sense. It is the majority and the minority together who represent the people as a whole and their general interest. But what about the single chief executive? All attempts to lift a chief executive above parties have proved abortive. A disastrous example is provided by the institution of the presidency under the German republican (Weimar) constitution, where the superpartisan president eventually betrayed the republic. The third (French) republic narrowly averted a similar fate. Such insistence upon the nonpartisan character of the chief executive is a result of the persistence of ideas prevalent during the monarchical age, when the king or the crown was supposed to be the preordained representative of all.

Dual Nature of Representation.—Historically speaking, representative assemblies developed in most European countries in the course of the later middle ages as an important part of the mediaeval constitutional order. Though great variations existed, the three estates were usually composed of nobility, clergy and the merchants of the cities (the burghes). In the English parliament the higher nobility was joined with the higher clergy in "the lords spiritual and temporal," while the lower squires and the burghes together constituted the commons. This system of two estates proved more viable than the commoner continental system of three. The representatives of the lower estate were originally called by the crown in order to secure additional financial support over and above the feudal dues. (See *FEUDALISM*.) Quite naturally, these representatives when gathered together proceeded to present complaints and petitions in an effort to strike a bargain. Such bargains were in favour of their own class. They represented their class as agents of the local powers and acted under instructions or mandates. But when, after the deal was struck, the king and the two houses of parliament acted together as "the king in parliament," they were taken to represent the whole realm. This historical background shows clearly that we are not justified in drawing the sharp distinction Burke had in mind between agents with definite instructions and representatives speaking for one nation. An elected body is both: a deliberative assembly from *one nation* with *one interest*, that of the whole, and a congress of ambassadors from different and hostile interests. We cannot escape from this dualism in political representation. Many political philosophers have tried to do it, but with unsatisfactory results. Thomas Hobbes's monistic conception, like that of fascists and Communists, is forced into seeking some kind of religious or inspirational sanction, deifying the state, or the proletariat, or the folk and their respective leaders. The dualism of representing both the whole and one or another of its parts lies deeply embedded in representative schemes.

Representation Defined.—In the light of the foregoing, it is possible to suggest a definition of political representation: Representation is the process through which the attitudes, preferences, viewpoints and desires of the entire citizenry or a part of them are, with their expressed approval, shaped into governmental action on their behalf by a smaller number among them, with binding effect upon those represented.

Some features of this difficult definition require further comment. We speak advisedly of attitudes, preferences, viewpoints and desires, rather than of will, influence or control, because the large citizen bodies of modern times do not possess a clearly defined will in most matters of public policy, because of lack of knowledge. We use the general expression "governmental action," rather than legislation or policy, because all kinds of governmental activity are expressive of popular reactions. Perhaps the most important part of this definition is the phrase "with their expressed approval." Since such approval can be secured only periodically, it must be in a form covering a specified period of time. No setting such as that of the German National Socialist regime can be called truly representative; for although the original grant of power was secured for four years, Adolf Hitler set this limitation aside and no one was able to challenge him. Hence, nothing done after 1937 can be called representative of the German people at large. Finally, it is essential for genuinely representative action that it be accepted by those represented as theirs

and hence binding upon them in all its consequences—a result which flows from their expressed approval. But while periodic elections are the commonest method for demonstrating expressed approval, there are exceptions, such as courts, where the expressed approval may be found in a constitution adopted by common consent, or in a special interest represented, as in so-called economic councils.

SOME HISTORICAL AND CONSTITUTIONAL ASPECTS OF REPRESENTATION

Representative systems of the rationalized type are a modern growth. They certainly were not found, as Montesquieu implied, in the forests of ancient Germany. We have seen that political representation arose as part of the mediaeval constitutional order. Like so many mediaeval institutions, this political representation drew its inspiration from the church, whose vast body of the faithful was presumably represented by the great councils in which all Christian people were believed to be present.

Reasons for the Late Appearance of Representation.—But why did representation appear so late in the history of mankind? Essentially, the answer must be that it was not needed before modern times. The great empires of Asia had been animated by religious beliefs in which the individual human being counted for little and his personal preferences for less. In classical antiquity, with its city-states in which the personalist sense of man's dignity first crystallized, the small number of citizens permitted personal participation. Aristotle deemed this participation so vital that he opposed altogether a political framework larger than the average city-state. This necessity for personal participation became impossible of fulfilment whenever such a city-state expanded beyond the local unit. Attempts to solve the problem through federal organization foundered because of the lack of an ideological base upon which a representative scheme might have been evolved. The Romans undertook to embody the citizenry of each city of their Latin federation in the Roman citizenry by using various fictions, but the system broke down when Rome expanded and the Romans adopted the Asiatic technique of deifying the emperor. Still, the Roman constitution unquestionably contained elements of genuine representation. These elements were crippled, however, by the ascendancy of the unrepresentative senate. By contrast, the spirit of corporate solidarity in the mediaeval towns, shires, monasteries and cathedrals was sufficiently developed to render the group willing to exercise its participation in the larger community through representatives. Unless such solidarity provides a common base of ideas, true representation cannot take place.

Representation and Constitutional Government.—Except in small communities, constitutional government is impossible without a system of representation. Constitutional government is government in which the use of power is restrained by a constitution which defines the functions of various authorities. Restraint is indissolubly connected with dividing governmental power. Undivided power is unlimited power.

From a historical standpoint, the need for securing responsibility in government is the central objective in all the various schemes of representation. This is true even of completely supernatural and irrational schemes, such as that by which a king is supposed to represent God on earth. For this notion may be the most powerful restraint upon him and provide an impulse for him and his officials to act justly and avoid abuse of power. Examples abound not only in the experience of Europe but in such systems as the sultanate of Turkey or the empire of China. But this scheme works only as long as the faith lasts. If the ruler becomes an unbeliever, the most arbitrary tyranny easily develops.

The division of power may take many different forms. Perhaps the two most important modern forms are the so-called separation of powers, and federalism. For both, representation is of vital importance. Distinct federal divisions of the electorate, created and maintained under a constitution, require the selection of distinct groups of representatives among whom the several functions of government may be divided. The same is true under

representatives for different constituencies. Looked at from this angle, these schemes for dividing "power" really amount to dividing the people in a number of different ways and then giving these several subdivisions a voice in shaping governmental action through different representatives who are kept from abusing their power by holding each other in check. Such a plan could, of course, have no practical effect unless the community were actually divided into a number of groups, parties and classes.

Not only does constitutional government depend upon representation, but representation in turn depends upon constitutionalism. For unless the community is ready to agree upon and live by a basic charter in accordance with which authority is exercised, plans for representation are liable to break down, as they did in Italy and Germany. The representative quality rests upon a belief in common ground as far as doing things is concerned, and while there is no need for agreement on fundamentals other than the constitutional mores themselves, the latter, which have sometimes been called constitutional morality, are indeed of paramount importance. Representation, we might say, is a game in which the rules are prescribed by the constitution as approved by the people.

Representation and Legislation.—Ever since the 16th century, legislation has been considered the most important phase of governmental action. Legislation involves the making of rules binding upon the whole community. Such general rules, it was felt, should bear the closest possible relation to the community's general beliefs. The higher law which Sir Edward Coke and others expounded as the yardstick for evaluating parliamentary statutes was believed immutable, a precious heritage of principles upon which all legislation should be based. At this point, the Protestant idea that one cannot force men in matters of belief, now generally accepted by all Christians as well as by many other faiths, suggested the necessity of consent in matters of general legislation. A specific act of government may be justified in terms of a specific emergency, but no general rule can be considered valid unless assented to by those to whom it is to apply. Since the citizenry is too large, representation becomes essential. "No taxation without representation" is a vivid expression of this general view.

There is another aspect which suggests the use of representative assemblies as the natural agents for the purpose of making laws. A general rule presupposes that there is a series of events which have certain aspects in common. There must be a normal situation. If an event is recurrent, time elapses. Time is available, therefore, for deliberation to determine what is right and proper. Deliberative processes are therefore well suited to the relatively slow procedure of representative bodies. Nevertheless, the procedure of a well-organized representative assembly is so arranged as to result in action; namely, the adoption of a general rule. The enactment of such a general rule requires careful co-ordination of conflicting viewpoints; really workable compromises need to be reached. Through argument and discussion the area of agreement is determined in the representative legislature. It symbolizes the consent which legislation presupposes, if it is to be compatible with the dignity of man's autonomy in matters of basic conviction and belief.

ELECTORAL SYSTEMS AND REPRESENTATION

In our discussion so far we have spoken of electing representatives as if an election were as simple a thing as throwing a stone. Actually, some of the most difficult problems of representation cluster around elections. Should elections be secret or public? Should limiting qualifications be required of those participating in the elections? How should the country be divided so as to make it possible for people to vote? These and similar issues have all been sharply debated at one time or another, with a view to their bearing upon the central issue of making the results representative.

To the ancients, democracy meant that the whole citizenry met in the market place and decided all matters of common concern. To the modern world, democracy means that the whole citizenry

their platforms in the newspapers or listened to them in a meeting or over the radio or television. But there is a great difference between those elections in which the citizen is confronted by a clear-cut alternative between electing either A or B, and thereby supporting either party X or party Y, and elections in which he must choose among A, B, C, D, E, F and so forth and thus align himself with one of at least half a dozen parties, none of which has any chance of securing a majority.

The English and U.S. System.—The so-called two-party system has long been traditional in the United States and Great Britain. British parliamentary government rested for a long time upon a strictly traditional system of elections. It abounded with abuses of all kinds, such as rotten boroughs. Through a series of reforms Britain eventually arrived, in 1884-85, at the single-member constituency, though the constituencies continued to lack uniformity of size and structure. Elections thereafter were decided in England by relative majority or plurality. This means that the candidate who secures the largest number of votes wins the seat. The elections are secret, though before 1885 they were public, with much brawling and rioting. The British electoral system is thus clearly directed toward the goal of dividing each constituency, and thereby all of the United Kingdom, into two parts: the majority which is to govern and the minority which is to criticize. This may mean permanent minority status for a man who belongs to the wrong party in a particular constituency. As the English economist Walter Bagehot (1826-77) once wrote (in *The English Constitution* [1893]), "I have myself had a vote for an agricultural county twenty years, and I am a Liberal; but two Tories have always been returned, and all my life will be returned." A Democrat in Vermont or a Republican in Alabama is in the same situation.

The main criticism brought against this system of single-member constituencies is that the number of representatives elected is usually not proportional to the ratio of votes cast. This is virtually certain to be the case, because in many constituencies one of the parties may predominate, as Democrats do in the southern states of the United States or Tories do in many rural constituencies in England. It may even happen that a minority of votes secures a majority of representatives.

Gerrymandering ("Electoral Geometry").—If the desirability of a majority (plurality) system of elections be conceded, the issue of how to divide the electorate appropriately is of great importance. As long as the population shifts, periodic readjustments of the boundaries of electoral districts are necessary, if gross injustices such as rotten boroughs are to be avoided. In the United States and elsewhere this issue is a familiar one; there is a recurrent political fight over reapportionment. Even with skilful and competent handling, there are bound to be lags. Under adverse conditions, reapportionment becomes a football of party politics. Since in order to gain a seat all a party needs is a small majority of votes, it is very tempting for the party in power to redraw the political map, that is, the boundaries of districts, wards and other subdivisions, so as to distribute its voting power most effectively. The resulting shapes of electoral subdivisions are often fantastic and not even always contiguous. Because a salamanderlike sprawling district was first constructed under a governor of Massachusetts, Elbridge Gerry, in 1812, this practice is known as gerrymandering. It is easy to construct cases which illustrate how the same electorate may give a majority to opposing parties as a result of adroit electoral geometry.

The Issue of Proportional Representation.—The nonproportionality of single-member constituencies electing representatives by pluralities as well as gerrymandering has given rise to a series of proposals for proportional representation which seek to remedy these defects. The idea first appeared in the French national convention in 1793, without practical results. It was further elaborated by the mathematician Joseph Diez Gergonne (1830) and developed independently by an English schoolmaster, Thomas Wright Hill, whose son took the idea to Australia (1839). At about the same time, in 1842, Victor Prosper Considérant proposed to the council of Geneva a proportional-representation scheme entitled *De la sincérité du gouvernement, lettre à M.M. les*

membres du grand conseil... de Genève. Two years later Thomas Gilpin published a pamphlet *On the Representation of Minorities of Electors to Act with the Majority in Elected Assemblies* (1844). About 12 years later the Danish minister of finance, Carl Andrae, worked out a system resembling the Australian plan, but using ballots. Finally, in 1857, Thomas Hare expounded the plan definitively in *The Machinery of Representation*, which he developed more fully in 1859 in his *Treatise on the Election of Representatives, Parliamentary and Municipal*.

From this rapid survey it is clear that proportional representation responded to a widely felt need. The underlying idea of all the various proposals was to secure a representative assembly reflecting with more or less mathematical exactness the various divisions in the electorate. Why should such divisions be reflected? "The voice of minorities should be heard," is the answer.

The most penetrating philosophical argument in support of this general idea was set forth by John Stuart Mill in his *Considerations on Representative Government* (first published in 1861), in which he called it "one of the very greatest improvements yet made in the theory and practice of government." After briefly outlining Hare's scheme of proportional representation, Mill set forth its "transcendent advantages." "In the first place, it secures a representation, in proportion to numbers, of every division of the electoral body: not two great parties alone... but every minority in the nation... Secondly, no elector would be nominally represented by someone whom he had not chosen. Every member of the House would be the representative of an unanimous constituency." Mill stresses the strong tie, the complete identification, the weakening of localism, the higher intellectual qualification of the representatives and the avoidance of collective mediocrity. Finally, Mill sees it as a check on "the ascendancy of the numerical majority" by offering "a social support for individual resistance... a rallying point for opinions and interests which the ascendant public opinion views with disfavour." In his enthusiasm, Mill calls proportional representation "personal representation" which offers a refuge to the "instructed elite." No objections of real weight could be seen by Mill, though in his usual deliberate manner he examines a few which he finds wanting. Yet it is obvious that his whole argumentation rests upon certain unexplained major premises. His is an extreme individualist argument which he reinforces by the undemocratic preoccupation with the enlightened few who might be lost in the shuffle of the ignorant mass.

But the key assumption is that there can be no representation of the whole without a representation of each of the whole's parts. What actually is the primary function of a representative assembly? Is it to represent or is it to do something else? To put the question is to answer it. The primary function is to participate in governing. In order to be able to do that, a representative assembly needs a measure of cohesion. It cannot be, as we have seen, solely a congress of ambassadors from different and hostile interests. It must be able to reach decisions.

The elusive quality of Mill's approach is made evident by the opposing view of Walter Bagehot, another eminent writer on government and a liberal like Mill, albeit more to the right. Bagehot, in reflecting proportional representation, put the following question: What will proportional representation do to the *functioning* of a parliament as we know it? Bagehot was a practical man, a banker, and his great achievement in this debate was to spell out what everyone knew in practice, namely, that the function of a parliament was twofold: (1) for the majority to support the cabinet in its conduct of the government, and (2) for the minority to criticize the actions of the government. This combination of action and criticism enables a parliament to represent the people as a whole.

Bagehot considers the basic difference between election by majority and proportional representation the fact that proportional representation makes the constituency voluntary—each voter individually is able to choose his own constituency. He votes as a voluntary member of a group which has no other tie. A constituency being the group or segment of voters which is entitled to send a member to parliament or congress, this is indeed the

basic point, although the language of proportional-representation advocates often obscures it. To put Bagehot's point another way, all proportional schemes suggest saying to the electorate: If a certain number among you, say 10,000, can agree upon a candidate, that candidate shall be elected. The majority system implies this approach: A certain number among you shall constitute an electoral district, and the one for whom the largest number among you vote shall be considered elected. "Under the compulsory form of constituency the votes of the minorities are thrown away. . . . Again this plan gets rid of all our difficulties as to the size of constituencies. . . . Again the admirers of a great man could make a worthy constituency for him." But central party organizations would acquire an overweening influence. "The crisis of politics would be not the election of members, but the making of the constituency. . . . The result of this would be the return of party men mainly. . . . Upon this plan, in theory voluntary, you would get together a set of members bound hard and fast with party bands and fetters infinitely tighter than any members now. . . ." These are brief bits from a memorable passage in Bagehot's *The English Constitution* which anticipated with remarkable clairvoyance some of the troubles that arose when proportional-representation schemes were actually tried. These arguments do not, of course, exhaust the problem. They are focused upon the issues which arise when the cabinet governs with the support of the majority of a parliament. They also fail to take into account the problems which arise when the divisions or cleavages among the electorate have gone so far that failure to represent them adequately would undermine the belief of the people in the justice of the constitution.

Theory and practice suggest that the truth lies somewhere between the lines of argument taken by Bagehot and Mill. There are situations, such as in multinational Switzerland, where proportional representation is probably to be preferred, but then parliamentary government should be discarded or at any rate considered very difficult of operation. There are others, such as in Great Britain, where the later evolution of parliamentary government, with its increasing emphasis on executive leadership, would seem to make a majority system advisable. In the United States the trend is in the same direction.

The Problem of Justice.—A broader philosophical issue which deserves special consideration is the justice of a representative system. Mill, in his plea for proportional representation, laid considerable stress upon this aspect. "There is a part," he wrote in *Considerations on Representative Government*, "whose fair and equal share of influence in the representation is withheld from them; contrary to all just government. . . . The injustice and violation of principle are not less flagrant because those who suffer by them are a minority. . . ." Mill considers this matter of justice to the minority so obvious that he proclaims representation in proportion to numbers the first principle of democracy. What kind of justice and democracy is this? Discarding for the sake of argument the extreme and atomistic individualism of Mill's approach, let us assume for the moment that representation should be that of individuals and that it is unjust to a minority not to be "represented," or "represented adequately." If there were only one such minority, perhaps it would not be too bad, although the number of representatives who would criticize rather than help to decide would be increased. It would mean less action, rather than different action. If there were many such minorities, so that no group any longer had a majority, it might mean complete inaction for long periods. This situation arose toward the end of the German republic and spelled its doom. It arose in France in the 1930s with disastrous effects, and again in the early 1950s. What then about justice for the majority? Is it not a question of competing claims? Why should the question of what is just to the minorities be given precedence over what is just to the majority? Admittedly, the majority wants some action. If such action is, through proportional representation, delayed or altogether prevented, what is the justice of that? Problems of justice are problems of adjustment between conflicting claims.

The election of representatives, therefore, always involves the parring down of some claims; justice can be achieved only through

a careful balancing of these. Presumably the majority's claims are heavier than those of any minority. Representation is a broad thing. The majority participates through acting, the minority through discussion and criticism. Proportionalists fail to consider the possibility that there might not be any majority at all, in spite of the fact that the need for action, and hence the existence of a majority, may be paramount. A just government is above all a government which governs. No government which fails to do that can possibly be just.

Experience with Proportional Representation.—As contrasted with the time when Mill and Bagehot wrote, we possess today a substantial body of experience with the workings of proportional representation. But the conclusions to be drawn from this experience divide the experts. On the one hand we have the enthusiasts for the

single-member constituencies with proportional representation by way of a transferable vote is employed. Switzerland makes use of a list system which gives the voter extreme freedom in making up his list and an almost mathematical representation of views in the community is achieved; yet the resulting complex party structure in the representative assembly permits effective action, because the Swiss do not use a parliamentary system of government. Finally, Ireland adopted the single transferable vote system long advocated by the British Proportional Representation Society, with virtually every county an electoral district. A critical evaluation of the different systems must be looked for in the special works suggested in the bibliography below. Suffice it to say that these countries found proportional representation compatible with their governmental tasks and settled down to a general acceptance of it. The same may be said of quite a few U.S. municipalities.

The conclusion regarding proportional representation is not simple. It all depends upon the group and class structure of the community, the constitution and pattern of the government at large, the extent to which foreign policy is vital and imposes its requirements of integration and consistency. The fact that Switzerland does well under proportional representation does not prove that the United States would do well also. Newton D. Baker, referring to the experiment with proportional representation in Cleveland, wrote as follows: "We have groups of all sorts and kinds, formed around religious, racial, language, social and other contentious distinctions. Proportional representation invites these groups to seek to harden and intensify their differences by bringing them into political action where they are irrelevant, if not disturbing. A wise election system would invite them to forget these distracting principles." (*Cleveland Plain Dealer*, July 25, 1935.)

This is one side of the medal. The other side is that proportional representation does provide an opportunity for political self-expression to minorities which are already crystallized as politically self-conscious groups. If the representative assembly is capable of integrating these conflicting groups, either by foregoing the task of "supporting" the government, as in Switzerland, or by renouncing content to co-operate with a monarchical head, as in the Scandinavian countries and the Netherlands, proportional representation may work better than a majority system. In many U.S. cities the city manager has provided a neutral balance wheel which enables a city council proportionally elected to function effectively.

In the last analysis, the problem of representation under modern conditions should be seen functionally in relation to the task assigned to the representatives. Legislation is one function, executive direction and leadership another, judicial and administrative determination something else again. Any system of representation, electoral or other, which works will be acceptable to the people at large and considered just; any system which fails to do so will be rejected or, as in Germany, will become a fatal flaw which may bring on the collapse of the entire governmental system. For technical as the problems of representation may seem, they relate to the very core of modern popular government: Unless the people can be made present in their thought, their opinions and their will, democratic government becomes

impossible.

BIBLIOGRAPHY.—Beside the broad philosophical discussions and some continental legal studies, there are only rather partisan analyses. The broad treatments of comparative government contain general analyses. Here might be mentioned Carl J. Friedrich, *Constitutional Government and Democracy*, chs. XIV, XV and XX (1950), and Herman Finer, *Theory and Practice of Modern Government* (1932). Special treatments are to be found in G. H. Hallett and C. G. Hoag, *Proportional Representation—The Key to Democracy* (1937), and F. A. Hermens, *Europe Between Democracy and Anarchy* (1931). An important source is still the *Report of the Royal Commission Appointed to Enquire into Electoral Systems*, Cd. 5163, and its *Minutes of Evidence*, Cd. 5162 (1910). For the U.S. system, see C. E. Merriam and H. F. Gosnell, *The American Party System* (1940). (C. J. FIN.)

REPRESENTATIVE GOVERNMENT: see REPRESENTATION.

REPRISALS, acts of retaliation by one belligerent to compel the other belligerent to refrain from committing unlawful acts of war, and to comply with the recognized laws and customs of war. Reprisals should only be taken in the last resource. They should not be excessive and in no case be of a barbarous character. They should consist of a repetition of the same or similar acts, and, so far as possible, should be inflicted, not vicariously, but on the actual wrongdoer. The only authoritative rule is to be found in the *Oxford Manual of the Laws and Customs of War on Land* (1880) of the Institute of International Law. For the extent to which neutrals may be involved, see NEUTRALITY.

Certain measures of redress, short of war, are also termed reprisals. At the present time they usually take the form of the occupation of a port or some part of the territory of the offending state, or the seizure of its customs duties, or the detention of its vessels lying in the territorial waters of the injured state, or the institution of a pacific blockade (*q.v.*).

See P. Cobbett, *Leading Cases on International Law* (1886); A. D. McNair, *The Legal Meaning of War and the Relation of War to Reprisals*, *Grotius Transactions* vol. II (1926).

REPRODUCTION, the process by which a living thing, whether plant or animal, gives rise to another of its kind, is commonly cited as one of the outstanding characteristics of living matter. In so far as biologists have ever been able to discover, all life comes from pre-existing life. No living thing has ever been found to arise directly from nonliving matter. The only possible exception may be the filterable viruses, so-called because, being particles too minute to be visible under the highest powers of the microscope, they have their size estimated by the smallness of the pores through which they will filter. Such viruses apparently possess most of the characteristics of living matter including that of reproduction. The reproduction may be, however, merely the capacity for duplication from the products of their own chemical activities, or for reorganization of the several ingredients of the nutritive matrix in which they are located. In other words, they may be operating merely as centres of crystallization, as it were, of the various constituents of the surrounding medium into an organization similar to their own. This power is seemingly possessed by various nonliving fermentlike substances. How such synthetic duplication differs from ordinary protoplasmic reproduction—if it does—is by no means clear, since they still know so little about the chemical basis of the latter.

By Division and Growth.—At some point in their life cycle living things give rise to other living things like themselves or which will come like them through a process of development. In one-celled animals and in the simpler many-celled types, reproduction commonly consists in a division of a parent form into two or sometimes into several descendants. True protoplasmic growth is increase of living substance, and inasmuch as reproduction is a continuation of such substance in the form of new individuals, it may be looked upon as a process of overgrowth.

For purposes of emphasis and discussion it is common practice to state the two great aims or ends of all living organisms as: (1) preservation of the individual, and (2) perpetuation of the race, but since these are both based fundamentally on nutrition they do not stand wholly apart. Growth is the outcome of nutrition, and reproduction may be regarded as a form of discontinuous growth. Constructive metabolism proceeds to a certain

limit, and then the organism divides, or part of it is detached and continues life activities as a separate individual. Or to state it another way, reproduction is a means by which metabolic activities established in a given individual are passed on to be continued in the form of new individuals.

By Germ Cells.—In more complex creatures reproduction is manifested by the giving off of special cells termed germ cells, or gametes, which either alone, or more commonly after pairing, give rise to new individuals. Germ cells which pair (fig. 6) are usually differentiated into macrogametes and microgametes, and commonly, particularly in animals, come to be borne by different parents which are then designated as male and female.

The Multicellular Body.—In unicellular organisms the new individuals may continue to live apart as independent cells, but in the more complex plants and animals the division products remain associated, growing and functioning as components of a more highly specialized order (fig. 11). The advantage in this is evident, since each unit cell, although in a large measure retaining its identity, can, together with certain of its fellows, specialize in the perfection of some particular function, while depending on neighbouring groups of cells for the more effective carrying-out of other functions necessary to the organism as a whole. Just as in human society it is advantageous to have such specialists as carpenters, electricians, shoemakers, bakers, merchants, teachers, doctors and others, so in cell aggregates specialization in different directions, as for motion, digestion, sensation and the like, permits of the development of a more complex and efficient organism.

Although certain unicellular forms and certain nutritive cells, such as egg cells, may be visible to the unaided eye, cells for the most part are of microscopic dimensions. The clue to their small size, and possibly to the reproduction of organisms by division in the first place, lies apparently in the physical necessity of maintaining a certain ratio between surface and mass in a functioning body. It is a physical law that surface increases as the square, and mass as the cube. Or to put it more concretely, when a cell doubles in diameter the mass to be nourished increases eightfold but the surface through which nourishment is to be absorbed and wastes discharged increases only fourfold. It is evident, therefore, that with any considerable increase in size, the supply of foodstuffs and oxygen from without and the elimination of wastes from within must fall below the needs of the cell since the surface becomes insufficient to provide for the exchange. The cell solves this problem by dividing, thus reducing mass and increasing surface. This necessity of maintaining a certain balance between mass and surface, indeed, is probably back of the first protoplasmic reproduction. As already noted, it is essentially a matter of overgrowth and division, or, in other words, discontinuous growth.

The Rise of Sex.—Superimposed upon this original method of direct reproduction, however, we find, even in the firstlings of life, the foreshadowing of sex. Beginning with the simplest organisms, temporary or permanent pairing of two individuals may occur before initiation of reproduction. Out of this has grown sex, and as a result unquestionably much of the complexity and diversity of all higher organisms, whether plant or animal.

To understand the significance of reproduction and the intricacies imposed upon it through sex, it is well to begin with its initial expressions in the unicellular organisms, most of which are too small to be seen without the aid of a microscope. Probably the simplest living things are the blue-green algae. Examining the one-celled body of the most primitive of these, one sees a homogeneous granular-looking material which is really of jellylike consistency. This is the essential living substance or protoplasm (*q.v.*). In these simple algae it is suffused by two pigments, a blue and a green, and is encased within a protecting and supportive wall—a lifeless product of the protoplasm itself termed cellulose. The green component, chlorophyll, is a pigment which is present in all green plants. Chlorophyll has the remarkable capacity of enabling plant protoplasm to utilize in the synthesis of food the energy supplied by sunlight. Out of the two simple raw materials, carbon dioxide (CO₂) and water (H₂O), which

when alone are devoid of available energy and possess no food value, chlorophyll enables the plant to build the simple sugar glucose, rich in usable energy. Part of the food thus manufactured is combined with nitrogenous ingredients of the cell to make new protoplasm, which serves for replacement and growth; some is stored as starch, or otherwise, and serves as food for future use.

Such cells as those of the blue-green algae are exceptionally simple in that apparently all parts of the protoplasm engage equally in the life activities; there are no specialized regions (fig. 1). Most cells, whether of single- or many-celled plants or animals, are differentiated into at least two distinct regions termed the nucleus and the cytoplasm or cell body. There is no clearly defined nucleus in the blue-green algae. In the nucleated cell the nucleus is usually discernible within the cytoplasm as a denser, more or less spherical body, sharply delimited by its own membrane. The cytoplasm, depending upon the kind of cell involved, may also contain other formed bodies, notably in all green plants beyond the blue-green algae, one or more bodies known as chloroplasts (fig. 2), within which the chlorophyll is confined and thus no longer diffused throughout the entire cell.

When the cell of a simple blue-green alga reaches a certain size, it solves the surface-mass relation by simply pinching in two in the middle to form two smaller cells. These in turn, wholly independently of each other, grow and repeat the process; and thus growth and reproduction are carried on indefinitely. This is perhaps the simplest conceivable type of reproduction. Commonly in various species of the blue-green algae the newly formed cells—two, four or more—may remain for a time side by side within a mucilaginous sheath (fig. 3). However, they continue to be mutually independent and eventually the "colony" breaks up and each individual goes its separate way.

There is also a group known as the green algae, so distinguished because they possess only the green pigment. Like the blue-green algae they may exist as one-celled individuals or in colonial form. A far greater complexity of structure is evident, however, in that the protoplasm is differentiated into three distinct parts or organelles: a central denser body or nucleus, which seems in the main to control the activities of the rest of the cell and bear the essential features of heredity; an irregularly shaped body, the chloroplast, within which the chlorophyll is confined and which is therefore endowed with the power to manufacture food, and the surrounding matrix in which they lie, the cytoplasm (fig. 2). The cytoplasm serves primarily to use the food manufactured by the chloroplast in the maintenance and growth of the cell and to regulate the interchange of materials through the cell wall.

Mitosis and the Genes.—Although the size and shape of the cell varies greatly among the different species of the green algae, each species retains this characteristic protoplasmic differentiation. To maintain the life activities and permit of growth, these cells like all others must divide from time to time in order to preserve the essential ratios of surface and mass. When the cell reaches a certain size-limit division occurs, but the operation is of more intricate nature than that seen in the blue-green algae. The process, termed mitosis, characterizing the cell divisions of all higher organisms, involves a series of changes that bring about a precise division of the nuclear contents. How accurate this is can be appreciated only after a careful study of the operation in progress. In mitosis special bodies known as chromosomes appear as the result of a rearrangement of the nuclear contents (fig. 4). These are of characteristic number and appearance in each particular kind of plant or animal. In man the number is 48. Ordinarily, when cell division occurs, each individual chromosome divides and thereby passes samples of all its contents on to the new cells. Pioneering studies by means of the highest powers of the microscope have revealed that each chromosome carries, chainlike, a series of still smaller units, the chromomeres, representatives of each of which are contributed to the new generation of cells. Evidence from various sources establishes that the fundamental units of heredity, the genes, reside in these individual particles or chromomeres, and that thus with their division and regrowth each newly formed cell gets a full contribution of the inheritance mechanism. All characteristics of living organisms

are primarily because of the influence of these genes, although in their expression, of course, environmental influences also play an important part. All hereditary differences involve differences in the genes of the individuals concerned.

Maintaining Numerical Constancy of Chromosomes.—Careful study has revealed that, in organisms characterized by biparental origin, the chromosomes are really in pairs, coming in single sets from each parent. In the cells of human tissues, therefore, there are 24 pairs, one of each kind from each parent. In mature germ cells this dual number is reduced to a single set in the finished germ—ovum or spermatozoon—and thus the numerical constancy is maintained. The separation is of such a nature that each definitive germ cell, while receiving only half of the original number of chromosomes, gets one of each pair (fig. 5); that is, one of each kind. If, for example, the original number of chromosomes is six—that is, three pairs—and we designate those which come from the father as ABC and those from the mother as abc, then the line-up for reduction-division may be any of those indicated in fig. 6. The individual chromosomes do not divide as in ordinary mitosis of body cells, but corresponding chromosomes merely lie side by side (paternal by maternal) and separate when the cell divides. Thus, whether a given chromosome of the reduced set is of maternal or of paternal origin is merely a matter of chance. The only necessity is that each final germ cell (gamete), whether of maternal or paternal origin, have one of each kind of chromosome, since each carries special hereditary determiners and has its own particular role to play in development of the new individual. That this is true is evident from the fact that the ova of certain animals can be stimulated by chemical or mechanical means to develop without being supplied with the second set of chromosomes, yet the new individual is complete in all its parts, though typically possessing only a single set of chromosomes in each of its various cells. If, however, one of each kind of chromosome is not represented, the developing form shows characteristic deficiencies, depending on which one of the single (haploid) set is missing.

Advantages of Biparental Inheritance.—The obvious advantage in biparental inheritance lies in the fact that young produced by the mingling of hereditary materials from two lines of ancestry will be, to some extent, unlike either parent. They will represent various combinations of ancestral traits and will, therefore, show considerable variety. Of the many new combinations some will be better fitted to survive than others under the prevailing conditions of existence. As many different paths of life present themselves, depending upon the survival value of their commingled ancestral traits, the combinations in certain individuals prove to be better fitted now to this, now to that niche in surrounding nature than do those of others. The weak, the ill-adapted are weeded out generation after generation; those most in harmony with their environment survive. Inasmuch as environment is never constant, and in the course of years may change profoundly, a perpetual premium is placed upon capacity for modification and adjustment. Thus, apparently, primarily through sexual reproduction, much of the bewildering variety of structure and pattern in living things which confronts us has been built up.

Variants in Reproductive Devices.—As one scans either the plant or the animal kingdom from the simplest to the most complex types, many variants in sexual reproductive devices may be observed. But all serve one final end; namely, the bringing together of two germ cells—commonly termed microgamete and macrogamete or, in animals, spermatozoon and ovum. These enter into a permanent union which constitutes the initial cell from which, through a succession of cell divisions, the new organism will arise. It is important to remember that no matter how discrepant these pairing gametes may be in size, they each carry the same number of chromosomes and therefore contribute the same number of genes.

In the simplest plants or animals the cells which unite may be of similar size; but, as forms rise higher in the scale of life, discrepancy in size becomes apparent until in the most complex organisms it may be extreme. The human ovum, for instance,

although itself only about $1/125$ of an inch in diameter, has a volume about 35,000 times that of the sperm (fig. 9), yet each contributes 24 chromosomes to the zygote.

Advantages of Dimorphic Gametes.—Apparently it has been found advantageous in organisms of biparental origin to have one of the gametes conserve stores of food for consumption of the newly developing form. But, since such increased bulk diminishes activity, a compensatory reduction in size commonly accompanied by motility develops in the opposite or male gamete. Moreover, inasmuch as the burden of effecting union has fallen largely to the microgametes, they have come to be produced in prodigious numbers, thus ensuring that one will reach and fertilize the more inactive macrogamete. In witness of this one has only to recall the countless millions of pollen grains, each bearing a microgamete, produced by a flowering plant, or the equally great numbers of spermatozoa carried in a single milligram of semen.

The occurrence of sex throughout the whole range of life, from all but the simplest organisms to man, is self-evident expression of its importance. It so pervades the make-up of the higher animals and plants that the significance of much of their structure and behaviour is interpretable only in terms of it. The reciprocal sexual structures and activities between the two forms we designate as male and female, whether in plants or animals, have come to their present state of mutual adaptation through millions of years of selection, and either set of such differences would be wholly meaningless without the other. Not only have special structures arisen which are connected with the reproductive system, but innumerable secondary characters such as devices to ensure pollination in plants, or ornaments which serve for allurements or sex-identification in animals, have appeared. There was much less intricacy in the make-up of living organisms during the millions of years of their existence before the coming of sex, but from that time on increasing complexities appeared in many groups and in many directions so that diversity of form and structure multiplied rapidly. It seems improbable, indeed, that living things could have become so remarkably complex without the establishment of sex.

Although the fundamental factors involved in reproduction, whether asexual or sexual, are readily discernible, the secondary differences in structures, activities and mutually adaptive relations which appear in both the plant and the animal kingdom become bewildering in their diversity. While most of these are interpretable in terms of special environing conditions, the paths of procedure are often very circuitous and the processes understandable only in terms of the distant ancestry from which modern forms have been derived.

In Unicellular Organisms.—Among one-celled organisms, whether plant (Protophyta) or animal (Protozoa), some form of division—equal fission as in the amoeba (fig. 3), budding or spore formation—is the dominant procedure even though it may be alternated, especially in the higher types, with occasional pairing analogous to the sexual unions of multicellular forms (Metazoa). In some members of the most primitive of the main groups of Protozoa (Rhizopoda, forms which can acquire large surface by the flowing out of pseudopodia) sex is possibly in a way foreshadowed in some in the coalescence of amoebulae into plasmodia as in the slime molds (Mycetozoa) from time to time. And the multiple conjugation seen in some Heliozoa and other protozoa, as well as in certain algae, may be a still further advance of the same nature. Such multicellular formations, through confluence of a number of individual cells, however, seem early to have given place to the union of only two cells, as seen in all higher organisms, and therewith the development of the bisexual form of reproduction characterized by the appearance of male and female types. In such protozoa as the colonial flagellate *Stephanosphaera*, the total fusion (conjugation) of two indistinguishable units (isogamy) occurs (fig. 8a); in others, such as *Vorticella*, the conjugating units differ in size (anisogamy, fig. 8b). In many different kinds of protozoa (for example, the radiolarians), special reproductive units (gametes) arise by division of the ordinary vegetative units. Such gametes are commonly dimorphic, and they unite in pairs to form a zygote, which may either grow into

the original form or subdivide into many smaller individuals.

In any discussion of the evolution of sexual reproduction the situation seen in paramonium, a member of the most complex class of protozoa, the Infusoria, is interesting and instructive. Paramonium (fig. 7) possesses a large oval nucleus (macronucleus) and, in a small depression in its side, a tiny, spherical micronucleus. The macronucleus seems to be wholly nutritive; the micronucleus, reproductive in function. Commonly the elongate animal reproduces by a simple transverse fission into two. After a number of such divisions—usually several hundred—the process is interrupted ordinarily by a temporary union of two individuals during which, after disintegration of the macronucleus and elaborate preparations of the micronucleus, micronuclear material is exchanged. The animals then separate and resume reproduction by division. Regrowth is rapid and, under favourable conditions, 4 divisions in 24 hr. may occur. Calculations show that a single paramonium could thus produce 268,000,000 offspring in one month.

Investigations have shown that although the individuals of a particular species of paramonium may look alike, nevertheless they are divided into mating types. Individuals of the one type, commonly the progeny of a single individual (clone), ordinarily will not unite with each other but will conjugate actively with members of other strains. In some species such as *Paramecium bursaria*, as many as eight distinct mating types have been identified, members of any one of which, though not conjugating together, would conjugate readily with members of any of the other seven types. Variants are known, however, in which members of one mating type will conjugate with only one or a few of the other mating types.

In nonconjugating strains of paramonium, however, a process of internal nuclear reorganization, known as endomitosis, occurs from time to time which apparently effects a physiological readjustment similar to that following conjugation. This suggests that some form of occasional constitutional reorganization is necessary. Although usually secured through nuclear exchange, under unusual conditions it may thus by endomitosis be otherwise accomplished.

The exhaustive studies of Prof. H. S. Jennings and his associates, made to determine in what respect conjugating and non-conjugating members of the same stock differ, are enlightening. One of the fundamental experiments was to divide a given strain into two parts and keep them under identical conditions, except that conjugation was permitted in one line and prevented in the other. The nonconjugating strains maintained about the same even rate of division, with no evidence of decline. In the conjugating strains, however, marked differences in division rate appeared in different families. Thus, hereditarily diverse families arose even though the conjugating strains were all derived from the same parental stock. Evidently great variety resulted from the new combinations of hereditary characters incident to the interchange of nuclear materials between the two conjugants. Some of the new strains thus secured were vigorous, others weak. Obviously, such combinations as possessed survival value under the conditions prevailing would result in the perpetuation of the fortunate strains. It is significant, furthermore, that unfavourable changes of the conditions under which these infusoria live usually induce conjugation.

Such facts among the protozoa bear out the inference already reached regarding the relation between sex and heredity in the higher animals, namely, that there is enormous insurance value in the constitutional diversity brought about by biparental inheritance—insurance that, in a changing environment, at least some of the variants will probably prove fit.

Rejuvenescence.—It is believed by some biologists that sexual reproduction not only results in a diversified progeny but that the fusion of the two germ cells, or the exchange of reproductive nuclei in protozoa, also commonly induces an actual rejuvenescence—a restoration of youth, as it were—to the protoplasm of the newly formed zygote. Professor G. N. Calkins has shown, for example, that in the protozoan *Uroleptus mobilis* actual rejuvenescence follows conjugation. In this species, after about

zoo or more divisions, in the absence of conjugation, the division rate slows down and the individuals pass into a decline followed by structural degeneration and death. Conjugation, however, renews the waning activities of the protozoan and initiates a new cycle of active growth and division.

Asexual Reproduction in Multicellular Organisms.—In the lower levels of many-celled animals and extensively throughout the plant kingdom, it is common for more or less of the parent body to separate off as a new individual which may or may not become wholly free. In some instances, as in the sea anemone, the entire body may split longitudinally into two. The fresh-water *Hydra* buds off new individuals when food is abundant. On the other hand, a starving *hydra* may reabsorb its own buds. Certain species of starfish multiply by separating off their arms (see REGENERATION). And various wormlike forms, especially among the flatworms and the nemertine worms, may divide into several pieces, each of which develops into a completely functioning individual. In certain cases the asexual multiplication leads to the formation of colonies in which the individuals remain attached, as in the zoophytes and corals, the polyzoa and the compound tunicates.

Among plants an endless variety of asexual reproduction is evident, ranging from the innumerable forms of bulbs or bulblike structures to the new individuals produced through the sending out of runners, as in the strawberry, which root at intervals.

Hermaphroditism.—Many common animals, such as hydras, flatworms, earthworms, leeches and snails may have both ovary and testis present in the same individual (hermaphroditism), though not uncommonly the ova and the spermatozoa mature at different times, so that in spite of their double sex there is cross-fertilization. In such forms as the earthworm, for example, when two individuals enter into sexual union, they pair in such a way that the sperm receptacles of each conjugant are stocked with spermatozoa from the other, and when the eggs are shed they are thus fertilized by spermatozoa from the other individual. In various of the internal parasites, such as the liver flukes and tapeworms, there is self-fertilization (autogamy).

Alternation of Generations.—Although the asexual mode of reproduction is common in all except the highest metazoa and in the great majority of the metaphyta, these all, for the most part, also exhibit sexual reproduction. The latter becomes of increasing importance in the ascending scale of structural complexity. The highest animals which show asexual reproduction in the adult stage are the Tunicata. Here, in the salps, a solitary, so-called nurse buds off a chain of sexual individuals which eventually separate. The alternation of a nonsexual polyp form with a sexual medusa form, seen in the Coelenterata, is one of the most commonly cited examples of alternation of generations (metagenesis). Hydroid colonies are formed in such small branching colonial animals as Obelia, for example, by growth and budding from an original free-swimming planula larva which has become attached. To the human eye such colonies look like minute branching plants attached to submerged objects in the shallow water along the seashore. At the end of each branch is a nutritive polyp. From time to time cylindrical individuals (gonangia) arise which come to bear small lateral medusa buds. These eventually mature and are set free as minute medusae or jellyfish. The free-swimming medusae produce ova and sperm and thus reproduce sexually. Each fertilized ovum grows into a polyp, which again by budding produces the original nonsexual colonial type.

A classical example of metagenesis also frequently pictured in textbooks is that of a much larger kind of jellyfish known as *Aurelia*. A free-swimming embryo becomes attached and develops into a polyp which, through a system of transverse budding (asexual reproduction), eventually becomes subdivided into a stack or column of saucer-shaped young medusae (ephyrae). These become free and swim away as individual jellyfish that produce ova and sperm and thus reproduce sexually. From the fertilized ova the new generation of polyps is produced. Not all coelenterates, however, exhibit such alternations of polyp and medusa generations. Many medusae are known in the life cycle of which there is no polyp form and the entire great group of

anemones and corals, though for the most part reproducing by division as well as by eggs, have no medusa stage.

In the early developmental stages of even the highest vertebrates, however, twins or even quadruplets may arise by division of a single egg or embryo. Identical twins in man, for example, are believed by some embryologists to arise in this way. And in such simpler mammals as the armadillo the quadruplets which constitute the usual litter are definitely known to have been derived from a single ovum. The same is true of the multiple embryos which spring from a common source (polyembryony) in such parasitic insect forms as *Encyrtus*. In such vertebrates as the amphibia it is a relatively simple laboratory experiment to separate the first two cleavage cells of the dividing ovum and demonstrate that each will then develop into a complete and normal larva instead of the half of one it would have been without the operation.

In plants alternation of sexual with asexual generations is conspicuous in mosses and ferns. In such plants one phase in the life history (sporophyte) has to do with the production of spores—special reproductive cells which develop without fertilization. The second phase (gametophyte) is characterized by the production of macrogametes and microgametes, corresponding to the ova and spermatozoa of animals. Such gametophytes, therefore, constitute the sexual generation. In ferns, for example, spores are discharged from spore cases located on the fronds. Such as land on moist soil or sometimes on the fern frond itself, develop into small sexual plants termed prothallia (gametophytes). These eventually develop the usual two types of sex cells, the macrospores and the microspores (fig. 10). When the egg cell of such a prothallus is fertilized by a sperm cell (antherozoid) it grows into the familiar fern plant (sporophyte). In flowerless plants, and in the primitive flowering plants known as cycads and ginkgos, the male cell (antherozoid) is locomotor as in most animals.

In flowering plants such alternate occurrence in one life history of two or more distinctive forms is not so obvious as in ferns and mosses, but close inspection shows that the male and female gametophytes exist in much reduced form as minute structures dependent on the sporophyte. The pollen grain, for example, is not itself a male germ cell but is really a minute gametophyte or bearer of the functional sperm cell. Likewise, the functional egg cell is borne by a female gametophyte or embryo sac which is a part of the flower itself (fig. 13). Looked at from the standpoint of alternation of generations the plant body which bears the flowers is the sporophyte, while special parts of the flower represent the gametophytes. Usually, an eight-celled structure, one cell of which is the egg cell, constitutes the female gametophyte (macrogametophyte); and (2) an even more reduced structure consisting of two sperm nuclei and a pollen tube nucleus constitutes the male gametophyte (microgametophyte).

The microspores form within the anthers (fig. 12) and upon nuclear division become pollen grains. The dehiscence of the pollen sacs frees the pollen. Shortly before or after being shed, a tube nucleus and two sperm nuclei arise from an earlier nucleus. One sperm nucleus eventually unites with the egg to form the fertilized egg or zygote; the other unites with the so-called fusion nucleus (see centre of embryo sac, fig. 13) to form a triple-fusion nucleus made up of three haploid sets of chromosomes. The zygote germinates to form the young sporophyte. The triple-fusion nucleus, in some seeds, gives rise to a nutritive endosperm around the embryo.

Where alternation of asexual with sexual generation occurs in either the plant or the animal world, it is usually associated with some advantageous hastening of productivity in favourable seasons of the year or under other special environmental conditions. In the competitions of living things the struggle is severe, and great numbers must be produced in order that a select few, adapted to the prevailing conditions, may survive and maintain the race. Commonly, the quickest and easiest way to get numbers is through asexual reduplication, leaving it to the slower and more intricate methods of sexual reproduction to establish from time to time that variability which is necessary as the basis for adap-

tive selection.

Dual Hosts.—Some of the most complicated life cycles are found under specially hazardous conditions of existence, where the chances against successful propagation are meagre. Numerous examples occur among the internal animal parasites. If parasites increased in too great numbers within a given host, not only would the host be destroyed but with it often the parasites themselves. This is avoided commonly by the utilization of two hosts, part of the life cycle being passed in one, part in the other. Thus, in such human parasites as malaria, for example, female mosquitoes from any of the several species of *Anopheles* are the sources of infection in man. Spindle-shaped cells (sporozoites), which invade the human red blood corpuscles, are injected from the saliva of the mosquito when she bites. These multiply by division within the red blood cells. Liberated through destruction of the corpuscles they enter new red cells, and the process is repeated until a large number of red blood corpuscles have thus been destroyed and the number of parasites enormously increased. Such reproduction in the blood cells of man (primary host) are asexual. Eventually male and female gametocytes are formed, but these undergo their final transformations and conjugation only if withdrawn from the blood of man into the stomach of the anopheles mosquito (secondary host). The resulting zygotes penetrate to the outer wall of the mosquito's stomach where, in saccule pockets, they undergo repeated nuclear divisions with the eventual formation of numerous spindle-shaped sporozoites. With the rupture of the surrounding sac, the sporozoites make their way through the body spaces to the salivary glands of the mosquito whence they are injected with the saliva into the human host.

Many similar examples of alternate hosts might be cited among both vertebrates and invertebrates, and the various devices hit upon for securing transmission from one host to another afford some of the most complex and perplexing chapters in the study of animal relations. In the common pork tapeworm (*Taenia solium*), for example, man, the primary host, becomes parasitized by eating underdone pork (secondary host) which contains the encysted larvae. When taken into the human alimentary canal, the small head, bearing suckers and a cirlet of hooks, attaches to the intestinal wall and the worm begins to grow rapidly in length by the formation of segments. These increase in size from the anterior toward the posterior end, new segments arising in the narrow neck region. The whole chain is regarded by zoologists as a colony of individuals. Without mouth or alimentary canal of its own, the parasite is wholly dependent upon the digested food in the intestine of its host. The terminal segments, filled with embryos, are shed from time to time and pass from the body of the host. When the embryos are swallowed by a pig, they become freed as six-hooked larvae which bore their way out of the intestinal tract and encyst as so-called "bladder-worms" in the muscles or other structures of the pig. They attain their adult form only when such infected flesh is eaten and they are released into the human intestinal tract. The chances against the perpetuation of such forms are obviously great, yet there is an abundance of both pork and beef tapeworms.

The Life Span.—In unicellular organisms there seems to be no death from old age. When an alga or an amoeba reaches a certain size and nutritional state, it simply divides and what was one living individual now is two (fig. 3). If death occurs, it is because of some harmful condition in the environment such as lack of food, existence of enemies or the like. The protozoan we view through our microscope has no dead ancestors; it is the direct descendant of the original of its kind. With the establishment of a body as distinct from the germ, natural death enters the scene. The cells which jointly constitute what we might call the vegetative individual eventually perish; only the reproductive individuals known as germ cells maintain continuity between successive generations.

Although, if we may judge from what we see in nature, the penalty paid for a body is death, the higher realizations of living matter could not have been attained without that combination of diversity and unity made possible through the association of spe-

cialized cells which make up the bodies of the more complex organisms. Under these circumstances, from the standpoint of survival value of the species, it is desirable for the individuals of today to give place eventually to those of tomorrow, because environmental conditions are never constant for extensive periods, and it is only by giving the reproductive variants a chance that new fitnesses may be established and prolonged survival be made possible. Insurance of the welfare of the species is the all-important accomplishment.

What determines the life span of any one particular species is not always evident, but it may be safely said that in general organisms live only long enough to ensure their continuance as a race or stock (see *Longevity*). Duration of life is, within generous limits, automatically adjusted to survival of the species. Where the hazards of existence are numerous or outstanding, the rate of reproduction is high and the number of offspring produced is great; where the risks are fewer and the individual is better prepared to cope with them, the rate is low (fig. 14). In general there is an automatic adjustment between length of life of the individual and the chances of the young for survival. Any extraordinary increase in numbers, as may happen with unusual abundance of food, favourable weather conditions or removal of natural checks, is eventually offset by such factors as competition within the group itself for food, disease incident to promiscuity and by the multiplication of enemies which feed upon its members. Either sudden increase or decrease in numbers is likely to prove disastrous. Slight fluctuations which do not upset the so-called "balance of nature" are more likely to prove safe.

PHYSIOLOGY OF REPRODUCTION

It is common knowledge that the majority of animals and plants have more or less definite times at which they breed, though the ova (estimated at 200,000 in man) are possibly preformed at birth. These depend often upon seasonal or environmental conditions and it is well known that spring and summer are the times for reproductive activity among birds, insects and a host of other animals. Unusual warmth or cold may hasten or check the periodic development of sexual activity and the accompanying internal and external changes which take place in the body. The connection between breeding and food supply is also generally realized. Moreover, where climatic and nutritive conditions are approximately uniform throughout the year, periodicity in the breeding habits of animals is often obliterated. Thus, Semper states that sexual periodicity is absent among molluscs, insects and other land animals in the Philippine Islands. On the other hand, the regularity of the migratory movements, which directly relate to changes in the reproductive organs and the instincts for breeding, occurs to a great extent independently of temporary climatic conditions, though not wholly so. (See *BRIMS, MIGRATION OF*.) It is clear, however, that, broadly speaking, the factors which control the periodic changes in the generative system in association with breeding are of two kinds, the external ones referred to above, and internal factors inherent in the animals themselves, and particularly in the essential reproductive organs. Before attempting to describe these changes and the manner in which they occur it will be well, briefly, to describe the reproductive organs, referring more particularly to the higher animals.

The Generative System.—Among vertebrates the sexes are nearly always separate, although a few species are hermaphrodite. The usual arrangement, however, is for each individual to have its own characteristic sexual organs, those of the other sex, it is represented at all, failing to develop or undergoing early degeneration. In the male of all lower vertebrates (including birds) the

testes lie dorsally inside the body cavity and discharge their products, the spermatozoa, along with fluid secretions, into ducts communicating with the exterior by a passage (the *cloaca*) common to the urogenital and alimentary systems. In most mammals, on the other hand, the testes lie outside the main body cavity in a double sac (the *scrotum*) between the anus (or opening of the gut) and the penis. The testes are largely composed of tubules whose walls give rise to the spermatozoa and these latter are budded off into the interior as in other animals. Between the seminiferous tubules are *interstitial cells*. These give rise to chemical substances (hormones, *g.v.*) which pass internally into the blood. (See *ENDOCRINOLOGY*.) There is strong evidence that these internal secretions by their power of stimulation are responsible for the growth and development of the distinctively male characters and instincts. Thus, the presence of the testes is commonly regarded as the test for maleness.

In all mammals the spermatozoa pass out from the testis by a number of short ducts (the *ejaculatory ducts*) into a coiled tube lying alongside it (the *epididymis*). This acts as a storehouse for the spermatozoa until they are ejaculated. Spermatozoa may remain alive within the epididymis and still be capable of fertilizing ova for 30 days (rabbit). The epididymis is a long coiled tube with muscular walls and the coils lie in juxtaposition so that the whole forms one discrete body closely applied to the testis. From each epididymis a duct (the *ductus deferens*) passes back through the *inguinal canal* (a passage connecting the scrotum with the body cavity). The two *vasa deferentia* open close together in the common channel with which the urinary bladder also communicates. This passage (the *urethra*) is continued within the erectile copulatory organ or *penis*, at the end of which it opens to the exterior. In addition to these organs there are several accessory glands communicating with the common urogenital passage. These are the *seminal vesicles*, the *prostate gland* and *Cowper's glands*, all of which contribute fluid substances to the semen in which the spermatozoa swim; the secretions are believed also to cleanse the urethra of urine prior to the ejaculation of semen. The above description applies more especially to man, but in the majority of the lower mammals the organs are similarly arranged.

The ovaries, the essential reproductive organs of the female, likewise serve a double function. They produce the ova and also elaborate internal secretions comparable to those of the testes; these secretions are responsible for initiating the development of the female characters, as well as being a necessary factor in the sexual and reproductive processes. In the lower vertebrates the ova are large because of the amount of food substances (yolk) contained in them (as with the egg of the fowl), but in mammals they are microscopic, each being about $\frac{1}{16}$ in. in diameter (this, however, is considerably bigger than a spermatozoon, which is about $\frac{1}{1000}$ in. in length). The ova are contained within little sacs (Graafian follicles). These begin by being very small, but as they approach maturity their cavities enlarge until they protrude from the surface of the ovary; eventually (unless, as often happens with many of them, they have degenerated) they discharge their ova to the exterior in *ovulation*.

The ovaries are attached, one on either side, to the dorsal wall of the abdominal cavity by the *broad ligament*. The tubes which convey the ova to the exterior are also suspended by this ligament, a double fold of tissue arising from the wall of the body cavity. In the lower vertebrates the oviducts are provided with glands secreting albumen or egg white which coats the ovum as it passes down the tube. The egg shell in those animals in which it is formed is also secreted by a gland; in birds this is at the posterior end of the oviduct just in front of where it opens into the common urogenital passage. At the anterior end each oviduct has a fibrillated trumpet-shaped aperture which expands at ovulation and receives the eggs as they pass into the body cavity. The interior of the expanded end is provided with cilia which direct the passage of the ova into and down the tubes. The oviducts are usually paired to correspond with the ovaries, but in birds only the left ovary and oviduct are present. In mammals and birds the ova are usually fertilized by the spermatozoa in the passage of the oviduct, but in the lower vertebrates (*e.g.*, most

fish) this often occurs outside the body. In mammals, the oviducts (small, somewhat-coiled tubes) swell out posteriorly to form the *cornua uteri*, or womb. These may continue double throughout their entire length and open separately into the vagina (rabbit) or after continuing separate for a considerable distance may unite together to form the *corpus uteri* or body of the uterus (cow, sheep, mare, bitch, etc.) or they may extend for only a short distance before opening into the corpus uteri, which is a sac or bag (man). At the hind end the corpus uteri narrows down to form a neck (*cervix*) and this opens into the vagina by the *os uteri*. The uterus is the organ which contains the developing young during pregnancy. It has thick muscular walls on the outside and a mucous membrane with numerous glands lining the cavity inside. These secrete a fluid which helps to nourish the developing embryo during pregnancy and supplies a medium in which the spermatozoa swim after copulation. The vagina is the broad urogenital passage which extends backward through the pelvis and opens to the exterior at the *vulva*. The latter is constituted by all the female generative organs visible externally. The lateral boundaries are the *labia*, or lips. The *clitoris* is a small rod-like erectile structure and corresponds to the penis of the male but is solid.

The mammary glands, although not directly concerned with the reproductive processes, are dependent upon the ovaries for growth. They consist of milk-secreting tissue and are provided with ducts which convey the milk to the nipple, whence it can be drawn off.

The Reproductive Cycle.—At the approach of the breeding season in most animals the gonads (testes and ovaries) undergo marked growth. This is very pronounced in fishes and is hardly less marked in birds. Thus, in the sparrow in winter the testis is no larger than a grain of mustard seed but at the breeding season it reaches the size of a small cherry.

The male breeding season, when it occurs, is called the season of *rut*. The increase in the size of the testes which occurs prior to rut is accompanied by activity not only of the cells which give rise to the spermatozoa (the spermatogenic tissue of the seminiferous tubules) but also of the interstitial cells. In some mammals the testes are not permanently retained in the scrotum but descend thither at the beginning of rut and are withdrawn into the abdomen again after the rutting season is over (*e.g.*, many rodents). In insectivores (*e.g.*, mole and hedgehog) the testes descend periodically into temporary receptacles. In the mole it is estimated that the testes increase in size 64 times, and the seminal vesicles, prostate and other 'accessory glands' likewise show enormous growth. The time for sexual intercourse is continuous throughout rut, there being no short periods of quiescence within the breeding season as in the females of many species. Among domestic animals generally there is no special season of rut, the male being capable of service throughout the year, the semen evacuated normally containing an abundance of spermatozoa. In this respect these species differ from their wild ancestors, for in the undomesticated state the male usually experiences a rutting season at the same time as the breeding season in the female.

In the female mammal the times for sexual intercourse, instead of extending continuously over a season of considerable duration, as with the male, are restricted to periods of "heat" or oestrus. These may recur at rhythmical intervals within one breeding season (mare, cow, ewe, sow) or there may be only one oestrus to the season (bitch). The former condition has been described by Walter Heape as polyoestrus, the latter as monoestrus. The whole cycle of changes is known as the oestrous cycle. In the case of a typical monoestrus mammal, such as the dog, the oestrous cycle is divided as follows: anoestrus (period of rest); pro-oestrus (period of growth and preparation); oestrus (period of desire); pregnancy or (alternatively) pseudopregnancy.

During the anoestrus the reproductive system is, relatively speaking, quiescent. The Graafian follicles which contain the ova probably undergo slow growth and ripening, but they do not become conspicuous upon the ovarian surface until near the end of the anoestrus. The uterus is relatively anaemic and the

glands inactive. The mammary glands are also inactive unless lactation is in progress after recent pregnancy. The entire anoestrus in the bitch lasts about three months.

The pro-oestrus is marked by increased activity of the generative system generally. It is the time of coming on heat. The follicles come to protrude visibly from the surface of the ovaries. The uterus also undergoes growth, the blood vessels increase in size and number and the glands in the mucous membrane elaborate more secretion. At a slightly later stage a definite haemorrhage occurs in the uterus and blood is passed out to the exterior at the vulva. The mammary glands may also become slightly congested. The entire pro-oestrus lasts from one to two weeks and external bleeding may go on for ten days, but it is usually slight, consisting of no more than a sanguineo-mucous flow.

Oestrus or heat is the period at which (and, ordinarily, only at which) sexual intercourse takes place. It is marked internally by ovulation, that is, the rupture of the Graafian follicles and the discharge of the ova, which then become mature and ready for fertilization by spermatozoa. The wall of the uterus undergoes repair at this time but the glandular secretion is abundant and more liquid in character, to provide a suitable medium for the spermatozoa. In the bitch oestrus lasts about a week.

Oestrus is succeeded by either pregnancy or pseudopregnancy. Each of these periods in the bitch lasts about two months. At their termination the uterus and the generative organs pass back to a condition of rest, and so the oestrous cycle is repeated. The complete cycle takes about six months in the bitch, there being typically two cycles and two oestrous periods in the year but there is a good deal of individual and racial variation.

If pregnancy takes place as a result of fertilization of the ova, discharged during oestrus, these segment and become attached to the inside wall (mucous membrane) of the uterus, which grows around each of them. The structure formed in this way is highly vascular and serves as the organ of nourishment for the developing embryos to which the ova give rise. (See VERTEBRATE EMBRYOLOGY.) This organ is the *placenta* and is characteristic of nearly all mammals. The embryos are attached to the placenta of the mother by the outer of a number of membranes, and vascular processes (*villi*) grow out from this membrane (the *chorion*) into the hypertrophied uterine mucous membrane now forming the maternal placenta. Thus, a close connection is formed between the embryo and the mother and the placenta acts as an organ of respiration, supplying the developing young with oxygen brought thither in the maternal blood, and an organ of excretion, getting rid of carbon dioxide and the waste nitrogenous products, besides supplying the necessary nutriment. During pregnancy also the uterine muscles undergo a great hypertrophy, and are responsible for a great part of the increased weight which occurs in that organ. Thus, in the human subject, the virgin uterus weighs about 30 grams, whereas the same organ at the close of pregnancy, apart from the contained young, weighs 1,000 grams. It is through the rhythmical contraction of the uterine muscles that the young are expelled in parturition (the act of giving birth). The mammary glands undergo great development during pregnancy in preparation for the secretion of milk at its close.

If the ova discharged at ovulation are not fertilized during oestrus (as when coition does not occur) they die in the uterus and disintegrate. Nevertheless, in the bitch and many other mammals the uterus and mammary glands pass through growth-changes which, though not so pronounced, are similar in character to those during pregnancy. Thus, the mucous membrane becomes highly vascular and the glands greatly enlarge. The mammary glands also undergo marked development and toward the end of the period secrete milk. Even virgin bitches secrete milk freely about two months after the cessation of oestrus. At the end of this pseudopregnancy the generative system as a whole subsides into a condition of rest.

The ovarian changes (at any rate in the bitch) are also similar in both pregnancy and pseudopregnancy. The Graafian follicle, after parting with its ovum, becomes converted into the *corpus luteum*, or yellow body, so called because of a pigmented fat (*lutein*) formed inside it. The yellow body is formed by the

rapid hypertrophy of the cells surrounding the cavity of the follicle; this is so great that the individual cells increase in size 16 or 20 times. This structure, which plays an important part during pregnancy, lasts throughout that period (and correspondingly during pseudopregnancy) and then undergoes degeneration.

In polyoestrous animals there is a succession of oestrous periods within a single breeding season, that is to say, that if coition does not take place at the first oestrus, or if for some other reason the ova discharged at ovulation are not fertilized, the animal, instead of experiencing a prolonged pseudopregnancy followed by an anoestrus (as with the bitch), undergoes a short period of apparent quiescence, called by Hense the *dioestrus*, and then comes on heat again. Thus, with the sheep, the ewe, if she fails to become pregnant at her first oestrus, comes back to the ram (as the shepherds say) after about 15 days, and if she again fails, may experience a third oestrus after another 15 days, and so on for a succession of cycles until the breeding season is over or the ewe succeeds in becoming in-lamb. This short (or *dioestrous*) cycle in the sheep is therefore 15 days. The number of dioestrous cycles which the animal is capable of experiencing depends partly on the breed and partly on the environment, whether favourable or otherwise. Among sheep of all breeds there is a complete gradation between the monoestrous condition of certain wild varieties and the extreme of polyoestrous exhibited by certain merinos, in which there may be no anoestrus (even in the nonconception of pregnancy) but (in the absence of the ram) an unbroken succession of dioestrous cycles which last the whole year. Many wild animals (e.g., rodents) are polyoestrous and the dioestrous cycle may last for only a few days.

In polyoestrous animals ovulation typically occurs during oestrus and is followed by the formation of the corpus luteum. The time of persistence of this structure varies according to whether or not pregnancy occurs. In the absence of pregnancy the corpus luteum persists for the duration of the dioestrus and then begins to degenerate as if to make way for the ripening of a fresh batch of follicles in the ovary and a new oestrous period. If, however, pregnancy takes place the corpus luteum continues in the ovary until parturition as in monoestrous animals. In reality, the dioestrus, instead of being a period of complete rest, is of the nature of a very abbreviated pseudopregnancy, and the uterus undergoes some growth changes in association with the presence of the corpus luteum in the ovary.

In man there is typically no anoestrus (except among the Eskimos in winter) and the menstrual cycles, each lasting about a month, correspond to the dioestrous cycles of the polyoestrous lower mammal. The actual menstrual phenomena probably represent the degenerative changes at the end of an abbreviated pseudopregnancy (or dioestrus) telescoped into the pro-oestrus of a new cycle. Ovulation takes place most commonly about the 14th day after the beginning of the menstrual flow but it may occur at other times, though rarely, in the week or ten days before the beginning of menstruation.

In some animals (rabbit, ferret) ovulation takes place only after coition. The actual process can be demonstrated in an anaesthetized rabbit whose ovaries have been exposed to view (J. Hammond). It is possible that in man also ovulation may sometimes require the additional stimulus set up by coition. In most domestic animals (bitch, sow, ewe, cow, mare) ovulation takes place spontaneously at or about the time of oestrus.

The Testis and Ovary as Organs of Internal Secretion.—It has been mentioned that the testis, besides producing the spermatozoa, is also an organ elaborating an internal secretion which is discharged into the blood. A similar statement may be made about the ovary. The evidence for these conclusions falls under three heads: (1) the effects of removing these organs (castration and spaying); (2) the effects of transplanting the testis or ovary into animals whose own gonads have previously been removed and (3) the result of injecting tissue extracts prepared from testes or ovaries.

The general effect of castration in all vertebrate animals is to prevent the development of the secondary characters of sex, that is, of those characters which, while correlated with the sex in

question, are not directly concerned with reproduction. This statement applies to ovariectomy or the extirpation of the ovaries in the female as well as to castration in the male. It is essential, however, that this operation should be performed early in life to have its full effect. It not only ensures permanent sterility (whenever it is done) but if performed on the young stops the development of superficial sexual characters as well as the accessory reproductive organs (prostate gland, etc.). Thus, in man, castration prevents the growth of hair on the face and various parts of the body and arrests the enlargement of the larynx and the consequent deepening of the voice normally characteristic of puberty in the male. In stags castration inhibits the growth of the antlers and in those breeds of sheep which are horned in the male and hornless in the female it prevents development of the horns; moreover, the horn growth is arrested at any stage of development at which castration is performed. With fowls, castration is followed by an arrest of the development of the erectile structures about the head (comb, wattles, etc.). Castration has been practised on the domestic animals from the earliest times, for it improves the quality of the flesh and favours fattening in meat-producing animals and is conducive to a greater tractability in working animals since the disturbing effects of sexual desire no longer occur.

If the testes are removed from the normal position and grafted to an abnormal one (or if the testes of another male are transplanted immediately after castration), the organs exert their usual influence on the secondary sexual characters and accessory sexual glands, although their normal nerve connections have been severed. Since, then, the influence of transplanted organs can not be through intermediation of the nervous system it would seem that it must operate through chemical substances passed into the blood and so into the general circulation. Thus, in experiments upon fowls the testes have been removed and broken up into pieces, which have attached themselves to different parts of the alimentary canal or the wall of the body cavity, and the birds have developed into typical cocks with comb, wattle, etc., male voice and sexual and combative instincts. Furthermore, the experiments of Eugen Steinach and others have shown that the grafting of testes into females whose ovaries had been removed may cause the development of secondary male characters and bring about a partial or complete reversal of sex. For the successful implantation of testis tissue, as with most other organs in higher vertebrates, the material to be transplanted must come from an animal of the same species; in salamanders and frogs sometimes grafts may become incorporated and persist in the host organism when the living transplant has come from a donor of different species. Mammalian testis grafts will secrete hormone when they are incorporated into any locality in the host organism, but the grafts will produce spermatozoa only when transplanted into the scrotum or in the anterior chamber of the eye. In these two localities the body temperature is sufficiently low to permit formation of completed spermatozoa. The scrotum functions as a test regulator effectively reducing the temperature

cavity or into a kidney the oestrous cycle is continued and the uterus remains normal. Since the ovary in such a position is without its normal nerve supply it is presumed that its influence on the organism is because of internal secretions passed into the circulation. The corpus luteum is also known to be an organ of internal secretion serving the special function of secreting into the blood substances essential for maintaining the raised nutrition of the uterus during pregnancy and for the development of the mammary glands, for if this structure be removed surgically pregnancy can not continue, the uterus lapses and the mammary glands fail to develop. The corpus luteum also plays some part in controlling the short or dioestrous cycle, for so long as it is present in its integrity heat can not occur; but if it is extirpated some days before a new oestrous period is normally due, the period occurs shortly after the operation of removal. Thus, Hammond, by squeezing out the corpus luteum of a cow, has induced oestrus after 9 days instead of the usual 19 to 21.

Internal Secretions and the Control of Reproductive Processes.—An understanding of the role exercised by internal secretions in the first establishment of a functional reproductive system at the age of puberty, and in the control of the rhythmical processes occurring during reproductive life, is largely a development of the 20th century. Internal secretions from the sex glands, while immediately responsible for the principal functional changes, are themselves regulated by the secretory activity of other endocrine glands, especially those from the pituitary gland.

Analyses of the oestrous cycles in the guinea pig, repeated approximately every 17th day, were made by C. R. Stockard and G. N. Papanicolaou in 1917, and five-day cycles in the rat were carefully described by J. A. Long and H. M. Evans in 1922. The inactive period of the cycle, or dioestrus, gradually changes to the pro-oestrus as renewed growth of follicles occurs in the ovary. The entire female reproductive tract—oviducts, uterus and vagina—become more vascular, increase in size and show active changes in their glands; the vaginal epithelium exhibits renewed cellular activity under the old epithelial wall, which is rather precipitously cast off into the cavity of the vagina. The period of oestrus, or acceptance of the male, in these small rodents is restricted to a few hours in comparison with several days for larger mammals; it occurs as follicular size approaches the maximum and as samples of the castoff vaginal cell wall show nucleated epithelial cells mixed with the old cornified cells of the vaginal epithelium. Ovulation occurs approximately 10 hr. after the first mating is permitted. The growth, or estrogenic, phase of the cycle is followed by the luteal or regressive phase and this involution period is indicated by the character of cells appearing in a smear taken from the vagina. The cornified cell stage of the smear is gradually superseded by one in which scattered leucocytes appear and the final quiescent stage of the dioestrus is characterized by a scanty smear composed of cells almost exclusively made up of leucocytes.

Thus, the state of the reproductive cycle can be diagnosed rapidly from the living female by means of examining a smear made from the open vagina. The known correlations between the character of the smear and the ovarian condition makes it possible to determine the condition of the ovary simply from microscopic examinations of the vaginal smear. Since removal of the ovaries abolishes all cyclical phenomena as well as recurrent phases of pregnancy on the part of the uterus and vagina, the vaginal smear technique provides a rapid test for the estrogenic hormones introduced in these changes in the reproductive tract, and thereby has been tremendously in efforts to identify the source and to follow the procedures of isolation of these hormones.

The fundamental activities of the sex glands (testes and ovaries) are not self-regulating phenomena, but were shown clearly to be dependent upon secretions from the anterior lobe of the pituitary gland by Philip E. Smith and Earl T. Engle in 1927. This sex-gland activity involves both the formation of mature germ cells and the hormone secretion by the respective sex gland. Removal of the pituitary gland (hypophysectomy) in the adult animal leads to immediate involution of the sex glands, with loss of capacity to mature sex cells and inability to secrete hormones. Conversely, the introduction under the skin of a normal animal

characters. It done before puberty the uterus and mammary glands do not develop and the general bodily form tends toward a neutral condition not dissimilar to that of the castrated male. If performed after puberty ovariectomy is followed by cessation of the oestrous or menstrual cycles and the uterus undergoes atrophy in much the same way as occurs normally at the menopause (climacteric) or time of permanent cessation of reproductive activity (in women at from 45 to 50). If, however, the ovaries (or one of them) instead of being removed are grafted to an abnormal position such as the ventral wall of the body

of finely ground fresh pituitary substance, or extracts made from fresh or dried pituitary tissue, rapidly stimulates excessive activity on the part of the gonads. Defective secretion of pituitary hormones introduces defective activity on the part of the testis or ovary.

Some notion of the delicacy of interaction between the gonads and pituitary body can be appreciated from a knowledge of the regularity in the short recurrent oestrous cycles, and such phenomena as menstruation in the human females, as well as from the regularity in the strictly annual breeding cycles. In many wild mammals the gonads are active for but a short span of the year. During the periods of low gonadal, or reproductive, activity the pituitary gland is far less potent in stimulating sex-gland activity when introduced into a test animal than it is at the approach of the breeding season. Also, since the sex glands of the sexually inactive seasonal breeding animal can be stimulated rapidly into intense activity it becomes evident that the problem of the control of the seasonal sexual activity is essentially the problem of seasonal pituitary activity. What, then, is responsible for the secretory activity of the pituitary gland that regulates the seasonal sexual cycle?

The external environment as well as internal conditions both play a role in these reproductive processes and in the secretory activity of the pituitary body. Different elements in the external environment are involved in the regulatory mechanism of different species of animals and probably in the same one. The relative lengths of day and night have marked influences on the reproductive state of birds especially, as well as of some mammals, whereas other animals, particularly hibernating ones, appear to be less responsive to light changes. The experiments of William Rowan (1926) on the small migrant bird, the Junco, in the Canadian northwest pointed to light as a factor of greater significance than food or temperature in the control of seasonal sexual activity. Males of this small bird show high testicular activity in the month of May, and after the mating season they experience severe involution of the testes. When captive birds in outdoor aviaries were maintained over winter, testes were small and inactive until the month of February or March, but with a gradual daily increase in the length of the light period, provided by electric bulbs for periods of 10 min., beginning in fall the testes became fully active and produced spermatozoa in November and December in temperatures as low as -40°F . From this sexually active condition the sex glands underwent regression as the days were gradually shortened. Jacques Benoit (1937) demonstrated clearly that the effect of added light was indirect in that it incited the pituitary gland of light-treated ducks to greatly increased secretory activity.

In similar manner the breeding season of several wild game birds (wild turkey, pheasant, quail), some mammals and fish have been tremendously modified. Other animals respond apparently to temperature changes as one factor in the environment that regulates the breeding season and still other unknown elements probably play a part.

The secretion of substances (hormones) by the pituitary gland in the adult animal, that so markedly affect the reproductive system, is modified by factors other than light. The nutritive state of the animal is important. Simple inanition or starvation affects the secretory activity of the gland; lack of vitamin B₂ (lactoflavin or riboflavin) in the diet has a similar effect. The concentration of sex hormones in the circulation tends to inhibit secretion of the substances acting upon the gonads, hence a reciprocal gonadal-hypophyseal interaction constitutes at least one contributory element to the intimate control of the reproductive cycles.

The initiation of sexual activity, or the condition commonly known as puberty, depends upon the secretory activity of the pituitary gland. Prepubertal animals can be thrown into reproductive activity long before it normally occurs if pituitary secretions are merely introduced under the skin. Young hatched male chicks receiving pituitary extract for the first 12 days after hatching develop enormously enlarged combs and wattles, utter squeaky crowing sounds and attempt to tread their young pen mates.

Other organs of internal secretion than the pituitary gland

probably play a definite role in the control of breeding cycles. This appears to be true for the thyroid secretions in some animals and less definitely for other products of internal secretion.

Fertility and Sterility.—The number of spermatozoa discharged in a normal ejaculation of human semen is estimated at 226,000,000, whereas the number of ova ejected at one ovulation is usually only 1. For mammals generally the number of ova discharged is on an average only slightly more than the average number of young in a litter. It follows that the female rather than the male controls the size of the litter. (On the other hand, Sanders has shown for horses that a reduction in the number of spermatozoa may reduce the chances of the ovum being fertilized.) The sheep discharges one or two (sometimes three and rarely more) ova at estrus, but by flushing the ewes, that is supplying them with extra or stimulating food before and during breeding, the number may be increased and consequently a higher proportion of lambs obtained. This is an example of the influence of favourable nutrition upon fertility. Too high feeding (resulting in adiposity), however, promotes atrophy of the ova in the ovary and so is conducive to sterility. There is evidence also that sterility may be caused by the absence of certain essential accessory food substances or vitamins (*v. s.*) and that one such vitamin is present in green food (Herbert Evans). Degeneration of ova in the ovary may therefore be caused by faulty nutrition of various kinds, but some degeneration is normal.

Sterility may result from coition at an inappropriate time, that is, at too long an interval before or after ovulation, for Hammond has shown in the rabbit that the ova are not capable of being fertilized for longer than four hours after their release from the ovary, and that the spermatozoa in the female passages do not retain their power of fertilization for more than two days. (In the male passage, where they are quiescent, they retain this power for 30 days.) It is probable that in many other mammals the duration of viability of the spermatozoa and ova is not widely different. In animals such as the mare, which has a prolonged oestrus (a week or more), sterile unions may well be the result of this cause (Hammond).

Artificial insemination is sometimes successfully resorted to in cases where sterility has been because of an abnormal constriction of the *os uteri* or to the presence of an acid secretion in the vagina. The practice is to inject the semen directly into the *os uteri*, thus avoiding the constriction or escaping the action of the abnormal secretion. Walton has found that the semen of rabbits may be kept in a fertile condition in tubes outside the body at a medium temperature for more than five days and that after a journey by post from Cambridge to Edinburgh the spermatozoa contained therein could still successfully fertilize ova with normal pregnancy as a result.

Fertility, like other characters, is capable of being transmitted from one generation to another. Thus, rams which were twin lambs stay hand on the tendency to produce twins to the next generation of ewes, and by breeding from rams which were twins the fertility of a flock may be increased.

REPRODUCTIVE SYSTEM. The reproductive system in some parts of its course shares structures with the urinary system (*q.v.*).

MALE REPRODUCTIVE SYSTEM

The scrotum is a pouch of integument which is divided into two compartments by a median septum. Each compartment contains a testis, an epididymis and a portion of the spermatic cord. The left half of the scrotum reaches a somewhat lower level than the right half in conformity with the comparative positions of the two testes. The integument contains coarse scattered hairs and well-developed sudoriparous and sebaceous glands. The deeper layers contain smooth muscle fibres, the dartos; contraction of these fibres draws the scrotum up and produces a corrugated appearance. Internal to the dartos there is a layer of laminated connective tissue, the intercolumnar (external spermatic) fascia, which is continuous at the abdominal inguinal ring with the intercolumnar fibres. The next layer, the cremasteric fascia, contains bundles of muscle fibres, the abdominal cremasteric muscle; these fibres are

derived from the internal abdominal oblique muscle; contraction of the cremasteric muscle tends to draw the testis toward the abdominal cavity. The subsequent layer of fascia, tunica vaginalis communis, is relatively thin and is derived from the transversalis fascia of the abdomen. The innermost layer, the tunica vaginalis propria, is a double layer forming the serous investment of the testis; it is derived from the peritoneum. The outer layer (parietal) is closely adherent to the tunica vaginalis communis, the inner layer (serous) completely invests the testis and a portion of the epididymis, when it dips between the testis and epididymis it forms a pocket, the sinus epididymidis.

During the development of the foetus an outpouching of the lower part of the abdominal wall occurs on each side to form the genital swellings; these later become the scrotum in the male and the labia majora in the female. With the descent of the testes into the outpouching, the ductus (vas) deferens and vessels and nerves of the testes are carried through the abdominal wall as the spermatic cord. The passage way thus formed is referred to as the inguinal canal; it is at first widely open but eventually forms only a flat-sided passage in the abdominal wall and is somewhat more than 3 cm. (1½ in.) in length. The entrance to the canal, the abdominal inguinal ring, is formed by the funnel-shaped expansion of the transversalis fascia as it envelops the spermatic cord; the exit from the canal, the subcutaneous inguinal ring, is surrounded by the aponeurosis of the external abdominal oblique muscle. The layers of the anterior abdominal wall are carried into the scrotum as coverings of the testes and spermatic cord.

The testes or testicles, the essential male organs of reproduction, are contained within the scrotum. Each is oval, about 4-5 cm. (1½-2 in.) in length and 2-3 cm. (¾ in.) in width, and has a strong fibrous coat (tunica albuginea), from which septa penetrate into the substance, dividing it into lobules in which the seminiferous tubules are coiled. The tubules of each lobule form a single duct (tubuli recti) which extends toward the mediastinum and there forms a plexus of tubules (rete testis). In this way the secretion of the gland is carried to its upper and back part, where from 15 to 20 small tubules (ductuli efferentia) pass to the epididymis. Each of these is convoluted before opening (conus vasculosus). Microscopically the seminiferous tubules consist of a basement membrane surrounding several layers of epithelial cells, some of which are constantly being transformed into spermatozoa or male sexual cells.

The epididymis is a soft body covering the entire posterior margin and the adjacent part of the outer surface of the testis. It is enlarged above to form the head (caput) and below is a lesser swelling the tail (cauda). The entire epididymis is made up of a convoluted tube about 6-7 m. (18-21 ft.) long. Between the head and the testis two small vesicles are often found (appendix testis and appendix epididymidis).

The ductus deferens is the continuation of the tube of the epididymis and extends from the tail of the epididymis to its termination on the posterior surface of the prostate, where it joins the seminal vesicle to form the ejaculatory duct. The ductus deferens ascends on the inner (medial) side of the epididymis to the subcutaneous inguinal ring, being joined in this part of its course by testicular arteries, veins, lymphatics and nerves to form the spermatic cord. After entering the subcutaneous inguinal ring, these structures pass obliquely through the abdominal wall, lying in the inguinal canal, until the abdominal inguinal ring is reached. There they separate and the ductus deferens passes down the side of the pelvis and turns inward along the posterior wall of the bladder to the prostate, at which point it meets its fellow of the opposite side. It is remarkable for the thickness of its muscular walls. The ductus deferens presents a uniform diameter of 2 to 3 mm. until it reaches the seminal vesicle; there it broadens out and forms the ampulla ductus deferentis, the lumen of which presents numerous sacculations (diverticula ampullae). Immediately before joining the excretory duct of the seminal vesicle the ductus deferens again becomes rounded and slender.

The seminal vesicles (vesiculæ seminales) are two saclike appendages of the ductus deferens that lie upon the posterior surface of the bladder, parallel and lateral to the corresponding ductus

deferens. The vesicle is a tubular structure, 10 to 12 cm. long, which is folded back and forth on itself to be contained within a fibromuscular capsule. Arising from the main tube are a varying number of blind pockets or diverticula. The excretory duct of the seminal vesicle joins the ductus deferens to form the ejaculatory duct; these are narrow and thin-walled, and run side by side through the prostate to open into the floor of the prostatic urethra.

The prostate is situated just below the bladder and is traversed by the urethra and the ejaculatory ducts; it is somewhat conical with the base upward in contact with the bladder. The vertical dimension is from 2.15-3.0 cm. (1-1½ in.), the transverse diameter from 3.5-4.0 cm. (1½-1½ in.), and a thickness from 2-2.5 cm. (¾-1 in.); the size is liable to great variation with marked increase in elderly individuals. The prostate is composed of both glandular and muscular tissue and is enclosed by a fibrous capsule from which it is separated by the prostatic plexus of veins anteriorly. Microscopically it consists of masses of long, slender, slightly branching glands, embedded in unstriated muscle and fibrous tissue; these glands open by delicate ducts (about 20 in number) into the prostatic urethra.

The urethra is the canal which begins at the bladder and runs through the prostate and perineum to the penis, which it traverses

as far as the tip. It serves for the passage of both urine and seminal fluid. The urethra is divided into a prostatic, a membranous and a cavernous part. The prostatic urethra is about 3-3 cm. (1½-1 in.) in length; there is a longitudinal ridge (urethral crest) on its posterior wall, on each side of which the numerous ducts of the prostate open. Near the lower part of the urethral crest is a little pouch, the prostatic utricle, which is regarded as the morphological equivalent of the vagina and uterus. Close to the opening of the utricle the ejaculatory ducts have very small openings. The part of the urethra above the openings of these ducts really belongs to the urinary system only, though it is convenient to describe it here. After leaving the prostate the urethra

runs forward for about 1 cm., lying between the two layers of the urogenital diaphragm, both of which it pierces. This is known as the membranous urethra; it is the shortest, narrowest and least distensible of the segments and is surrounded by the fibres of the sphincter urethrae muscle. The cavernous urethra is that part which is enclosed within the penis after piercing the inferior layer of the urogenital diaphragm. Its length varies, but averages about 14 cm. (5½ in.). At first it lies in the substance of the bulb and, later, in the body of the corpus cavernosum, while finally it passes through the glans. In the greater part of its course it is a transverse slit, but in traversing the glans it enlarges considerably to form the fossa navicularis and there, in transverse section, it looks like an inverted T, then an inverted Y, and finally at its opening (external meatus) a vertical slit. Into the whole length of the urethra, mucous glands (urethral glands of Littre) open. As a rule the meatus is the narrowest part of the whole canal.

Opening into the cavernous urethra, where it passes through the bulb, are the ducts of two small glands known as Cowper's glands (bulbourethral glands), which lie on each side of the membranous urethra.

The penis, the male organ of copulation, is made up of three cylinders of erectile tissue, covered by skin and subcutaneous tissue without fat. In a transverse section two of these cylinders (the corpora cavernosa penis) are above, side by side, while the third (the corpus cavernosum urethrae) is below. At the root of the penis the two corpora cavernosa penis diverge, become more and more fibrous in structure, and are attached on each side to the inner border of the pubic arch, while the corpus cavernosum urethrae enlarges to form the bulb. The whole length of the latter corpus is traversed by the urethra. The anterior part of the penis is formed by the glans, a bell-shaped structure, continuous with the corpus cavernosum urethrae and having the conical ends of the corpora cavernosa penis fitted into depressions on its proximal surface. On the dorsum of the penis the rim of the glans projects beyond the level of the corpora cavernosa penis (corona glandis). The skin of the penis forms a fold which covers the glans (prepuce or foreskin); when this is drawn back a median fold, the frenulum praeputii, is seen running to just below the meatus. After forming the prepuce the skin is reflected over the glans and there looks like mucous membrane. The structure of the corpora cavernosa penis consists of a strong fibrous coat, the tunica albuginea, from the deep surface of which trabeculae penetrate the interior and divide it into a number of spaces which are lined by endothelium and communicate with the veins. Between the two corpora cavernosa penis the sheath is incomplete and, having a comblike appearance, is known as the septum pectiniforme. The structure of the corpora cavernosa urethrae and glans resembles that of the corpora cavernosa penis, but the trabeculae are finer and the network closer.

Blood Supply.—The superficial layers of the scrotum are supplied partly by the perineal branches of the internal pudendal artery and partly by the external pudendal branches of the femoral artery. The deep layers are supplied by the spermatic branches of the femoral artery. The veins accompany the arteries.

The testis and epididymis receive blood by way of the internal spermatic, a direct branch of the abdominal aorta and also from the deferential artery, a branch of the superior vesicle. The veins accompany the arteries.

The deferential artery supplies the ductus deferens; the deferential vein accompanies the ductus deferens to the base of the bladder, where it breaks up into a plexus and communicates with the pudendal plexus.

The seminal vesicle receives its blood supply from branches of the inferior vesicle and deferential arteries. The veins drain into the seminal vesicle plexus.

The penis is supplied blood chiefly by branches of the internal pudendal artery; however, the proximal part of the integument is supplied by the external pudendal arteries. The veins of the integument collect to form the superficial dorsal vein which later bifurcates to drain into the great saphenous vein of each side. The deep veins from the corpora cavernosa drain into a median deep dorsal vein which terminates in the pudendal plexus but

communicate with the internal pudendal veins.

The prostate receives its arterial blood supply from branches of the inferior vesical and middle haemorrhoidal, both of which are direct branches of the hypogastric artery. The veins form a rich prostatic plexus which communicates with both the hemorrhoidal plexus and vesical plexus, the blood eventually reaching the hypogastric vein.

Lymphatics.—The lymphatics of the scrotum terminate in the inguinal nodes. Those from the testis and epididymis unite to form several large stems that pass upward in the spermatic cord and terminate in the lower lumbar nodes. The lymphatics from the ductus deferens pass to the external iliac and hypogastric nodes. The hypogastric nodes also receive the lymphatics from the seminal vesicle. The superficial and deep lymphatics of the penis terminate in the superficial inguinal nodes with the exception of those from the glands and urethra which drain into the deep inguinal and external iliac nodes. The lymphatics of the prostate are very abundant and pass into the hypogastric nodes.

Nerve Supply.—The male reproductive system receives sympathetic fibres from the hypogastric plexus; those with fibres from the third and fourth sacral plexus constitute the nervus erigens, so called since stimulation of it produces erection of the organ. The following nerves supply ordinary sensation to the scrotum and penis: the external spermatic branch of the genitofemoral, the dorsal nerve of the penis and perineal branches of the pudendal, scrotal branches of the ilioinguinal, and perineal branches of the posterior femoral cutaneous. (C. M. Cs.)

FEMALE REPRODUCTIVE SYSTEM

Functional Anatomy.—In the human species as in most other vertebrates, the female reproductive system consists of a pair of ovaries within the body cavity and a tubular canal or duct which leads to the exterior. The ovary produces egg cells (ova) and sex hormones. The canal receives the egg cell and harbours the product of conception (embryo and its surrounding membranes) during the prenatal period of life. Different parts of the canal are specialized for particular functions. Its chief divisions (fig. 2) are: (1) right and left oviducts (uterine or Fallopian tubes) each associated with the corresponding ovary. They serve to conduct eggs directly into (2) the womb (uterus) where the embryonic contents become attached and where the embryo is nourished until birth. The uterus lies in the midline and consists of a body

(corpus uteri) and neck (cervix uteri) which opens into (3) the vagina, an organ of copulation.

The attachments of ovary, oviduct and uterus are such as to permit free and independent movements. All three are bound together by the sheetlike broad ligament which suspends them

from the walls of the pelvis; through it blood vessels, lymphatics and nerves reach them from below. The ovary has another ligament which supports blood vessels that enter from above. The two sets of vessels communicate so that blood may reach the organs by either route. The ligaments are so disposed that ovary and oviduct are screened off from the intestines and other pelvic organs. A muscular band (round ligament) passes from the uterus out of the body cavity and is attached to the outer skin. It corresponds to the gubernaculum testis of the male.

The mature ovary is a firm organ, about the size of a large almond shell, with a scarred or wrinkled surface. It lies within the body cavity and is suspended from the body wall so as to be freely movable. Near the surface there are many minute egg cells which have remained dormant since birth. Each is surrounded by a layer of flattened follicle cells; together they constitute a primordial follicle. More than 200,000 such microscopic follicles were counted in each ovary of a 22-yr.-old girl. From time to time, even before birth, certain primordial follicles begin to grow. As the egg cell enlarges slowly the follicle cells multiply rapidly, forming a thick wall about it. Fluid soon appears between the follicle cells and as this accumulates a small blisterlike sac is formed, the ovarian or Graafian follicle (figs. 2B and 3). The egg cell lies in its wall, the cells which immediately surround it forming a domed projection into the fluid which fills the follicular cavity. There may be several hundred such follicles in an adult ovary. The great majority degenerate but they are not useless since they are concerned in the production of ovarian hormones. Less than 400 follicles of the available thousands are likely to produce mature egg cells during a woman's reproductive period.

The oviduct is a tube of involuntary muscle with a cavity about 6 in. long, lined by a folded mucous membrane. The end toward the ovary is open, with a thin wall flared out like a funnel (infundibulum tubae uterinae). Its edges are frilled and folded; only one of the frills is anchored, being attached to the ovary. The rest of the tube has thick walls and like the funnel it can change its shape and position. It narrows near the uterus and where it passes through the thick muscular wall of the uterus its cavity is very small. Ciliated cells in the lining of the oviduct maintain a constant current of fluid from the body cavity toward the uterus.

The uterus, when not pregnant, resembles a flattened pear in size and shape, with the stem directed toward the vagina (fig. 2). This end is called the cervix; the rest is the corpus. Most of its thick wall consists of involuntary muscle. It has a slitlike cavity which extends laterally to the openings of the oviducts and is flattened from before backward. The cavity is triangular in form with the lower angle at the cervix (fig. 2). The lining of the corpus (endometrium) is a mucous membrane which is specially adapted for the reception and development of the fertilized egg. It has remarkable powers of regeneration, and it is constantly changing in structure and appearance during the reproductive period. In the nonpregnant state it may increase 10 times in thickness in the space of a month, i.e., during a menstrual cycle. It is covered by a single layer of secreting and ciliated cells which are continuous with tubelike glands that extend to the muscular layer. The glands are embedded in an embryonic type of connective tissue richly supplied with blood vessels. The superficial zone where the fertilized egg develops has a distinct set of arteries (fig. 3) which alternately dilate and contract so that the supply of blood varies rhythmically. The corpus is usually bent forward so that it lies upon the urinary bladder and is thus at an angle with the cervix, which is firmer than the corpus and less movable. It is cylindrical in shape and has many glands which secrete mucus. Its cavity is narrowed by interlocking folds of mucous membrane. At its lower end it protrudes into the vagina with which it communicates by a narrow slit (orificium externum uteri).

The vagina is a flattened muscular tube, its folded lining resembling the outer skin (epidermis) in structure. There are no glands but the surface is moistened by secretions from the uterus. At its lower end a thin fold of mucous membrane, the hymen, narrows the external opening in virgins. The external genitalia

(puddendum) consist of (1) a pair of skin folds, the lesser labia, which lie on either side of (2) a shallow trough, the vestibule, into which the vagina, the urethra (from the urinary bladder) and various small glands open. At the upper end of the vestibule is the clitoris, a small erectile organ, counterpart of the penis. These organs are usually completely covered by a pair of thick folds of hair-covered skin, the greater labia, which correspond to the scrotum of the male.

Development of Reproductive Function in Woman.—Before birth the infant's genital organs are stimulated by hormones which reach it from the placenta (q.v.). Such influences necessarily cease at birth and there is a regression which is particularly obvious in the cervix. During childhood there are no signs of activity but at the beginning of adolescence (8 to 12 years) the ovaries are activated by the hypophysis to the production of large follicles and hormones. The latter stimulate all parts of the reproductive tract and in addition the bony pelvis, breasts, hair (crines) and fat depots begin their progress toward maturity. There is a rhythmic alternation in the dominance of the hormones of the hypophysis and ovary. Eventually the hormonal tides attain a height which results in bleeding from the endometrium (menstruation), and the first menstrual period (menarche) appears.

Menstrual Cycles.—During the child-bearing period the sequence of events in the cycle is usually as follows: Under stimulation from the hypophysis at intervals of about a month, an ovarian follicle outstrips its fellows in growth and in a few days attains a diameter of about half an inch. Usually only one follicle enters upon this final growth period but rarely more may ripen. The enlarged follicle soon protrudes from the ovary like a clear blister. The ripened egg cell has become loosened from the follicle wall, and soon the outer wall of the follicle bulges, breaks, and the viscous follicular fluid wells out, carrying the egg along with it. This event is called ovulation. At about this time the hormone estrin reaches a peak in the blood stream and the oviducts, uterus and vagina are stimulated to great activity. It has been possible to peer into the body cavity of monkeys at such a time and see the thin-walled folds at the end of the oviduct wrapped closely about the ovary while both organs moved rhythmically. If spermatozoa are present the egg may be fertilized as soon as it is liberated. In any case it is swept into the oviduct where it is slowly moved along, reaching the uterus by the fourth day. The endometrium in the interim has been growing thick through cell division and the accumulation of fluid in the tissue. The glands have been secreting a watery mucus which moistens the surface. At about the time of ovulation the vessels are so dilated that the surface appears bright red and some blood corpuscles often leak out. The glands of the cervix have produced a quantity of mucus

FIG. 3.—A DIAGRAM TO INDICATE THE CHANGES IN OVARY AND ENDOMETRIUM DURING THE SUCCESSIVE DAYS OF THE MENSTRUAL CYCLE.

IN THE UPPER ROW THE FIRST TWO FIGURES SHOW A GROWING FOLLICLE, THE NEXT ITS RUPTURE WITH THE LIBERATION OF THE EGG (OVULATION). THE TWO FOLLOWING REPRESENT THE FORMATION OF THE CORPUS LUTEUM FROM THE COLLAPSED FOLLICLE, AND THE LAST THREE SHOW THE DEGENERATION OF THE CORPUS LUTEUM WITH THE CONCOMITANT GROWTH OF A NEW FOLLICLE WHICH MARKS THE BEGINNING OF THE NEW CYCLE. BELOW THE CHANGES IN THE GLANDS AND ARTERIES OF THE ENDOMETRIUM ARE SHOWN, ASSOCIATED AT FIRST WITH THE HORMONES OF THE FOLLICLE AND CORPUS LUTEUM AND THEN WITH THEIR REDUCTION WHICH RESULTS IN SHRINKING OF THE ENDOMETRIUM FOLLOWED BY BLEEDING FROM ITS DEGENERATING SURFACE

which plays a role in the survival of spermatozoa. The lining of the vagina has thickened by rapid cell division. This period is called the follicular phase of the cycle because it is dominated by the hormones of the ovarian follicle and is associated with its growth and rupture. Ovulation may occur as early as 7 days after the beginning of a menstrual period or it may be delayed for 18 days or even more.

The next phase of the cycle is called the luteal (or pro gravid) phase because it is dominated by an organ of internal secretion which arises from the walls of the ruptured follicle. It is called the corpus luteum, because in the human species it soon becomes yellow in colour. While the egg is in the oviduct, the thin walls of the collapsed follicle thicken rapidly. The cells enlarge and a meshwork of thin-walled vessels develops between them. The healing of the rupture point permits some fluid to accumulate in the cavity. The distinctive hormone of the corpus luteum, progesterone, produces changes in the uterus which make it a most favourable site for the reception and development of an embryo. The same changes occur whether the egg has been fertilized or not. During this time the contractions of the uterus are slowed down, the endometrium becomes more succulent, its glands become contorted and swell up with a secretion rich in nutrient substances. The arteries continue to grow and become more closely coiled. They play an important role in the subsequent events as was demonstrated by observations on the living endometrium in monkeys which have menstrual cycles very similar to the human cycle. If conception has not occurred the corpus luteum remains active for only 10 to 14 days. With the decline in its hormone output the blood flow to the uterus is reduced and the endometrium begins to shrink. Its superficial zone suffers particularly, for it is supplied by the coiled arteries which constrict for minutes at a time. This was observed in pieces of endometrium which had been transplanted to the eye where they could be watched continuously for hours at a time. In this location they may continue to show the cyclic changes for years. The reduced circulation and shrinkage were seen to persist for days in some instances, for shorter periods in others. This is called the ischaemic phase. Sooner or later superficial weakened vessels break and blood pours out into the tissue. Blood blisters may form which soon drain into the cavity of the uterus. This marks the beginning of menstruation (menstrual phase). The blood-soaked tissue soon loosens and sloughs off, leaving a raw wound surface. These observations illuminate many conditions that are found in microscopic preparations of human menstruating endometrium removed surgically. The endometrium continues to shrink during menstruation, and the processes of repair are rapid. Sometimes there is a period of relative inactivity before a new ovarian follicle enters on its final growth and initiates the changes of the next cycle.

Menstrual cycles continue more or less regularly unless interrupted by pregnancy. They are accompanied by various general bodily changes. A sudden fall followed by a rise in the basal temperature, for example, and a sense of exhilaration may be noted about the middle of the cycle when ovulation is most apt to occur. Rarely is abdominal pain experienced at this time. The relations between hypophysis and ovary may be affected by other hormones and by the nervous system as well. Changes in climate, living conditions, infections or psychic disturbances may consequently affect the rhythm. When the responses of the ovaries begin to wane at the age of 45 to 50 years, marked changes appear in the economy of the body as a whole and the hormonal balance is upset. (See also MENSTRUATION.)

EMBRYOLOGY

The development of the reproductive organs is closely interwoven with that of the urinary system (*q.v.*). It will here be convenient to take up the development at the stage in which the

FIG. 4.—DIAGRAM OF THE FORMATION OF THE GENITO-URINARY APPARATUS (SUPPRESSED PARTS ARE DOTTED)

genital ridge is seen on each side of the attachment of the mesentery; external to this, and forming another slight ridge of its own, is the Wolffian duct, while a little later the Müllerian duct is formed and lies ventral to the Wolffian. Until the fifth or sixth week the development of the genital ridge is very much the same in the two sexes, and consists of cords of cells growing from the epithelium-covered surface into the mesenchyme, which forms the interior of the ridge. In these cords are some large germ cells which are distinguishable at a very early stage of development. It must, of course, be understood that the germinal epithelium covering the ridge, and the mesenchyme inside it, are both derived from the mesoderm or middle layer of the embryo. About the fifth week of human embryonic life the tunica albuginea appears in the male, from which septa grow to divide the testis into lobules, while the epithelial cords form the seminiferous tubes, though these do not gain a lumen until just before puberty. From the adjacent mesonephros, or perhaps, coelomic epithelium, cords of cells grow into the attached part of the genital ridge, or testis, as it now is, and from these the rete testis is developed.

In the female the same growth of epithelial cords into the mesenchyme of the genital ridge takes place, but each one is distinguished by a bulging toward its middle, in which alone the large germ cells are found. Eventually this bulging part is broken up into a series of small portions, each of which contains one germ cell or ovum and gives rise to a Graafian follicle. Mesonephric cords appear as in the male; they do not enter the ovary, however, but form a transitory network (rete ovarii) in the mesovarium. As each genital gland enlarges it remains attached to the rest of the intermediate cell mass by a constricted fold of the coelomic membrane, known as the mesorchium in the male, and the mesovarium in the female. Lying dorsal to the genital ridge in the intermediate cell mass is the mesonephros, consisting of numerous tubules which open into the Wolffian duct. This at first is an important excretory organ, but during development becomes used for other purposes. In the male, as has been shown, it may form the rete testis, and certainly forms the vasa efferentia and globus major of the epididymis; in addition to these, some of its separate tubes probably account for the ductus aberrans and the organ of Giralde (see fig. 4). In the female the tubules of the epoöphoron represent the main part, while the paroöphoron, like the organ of Giralde in the male, is probably formed from some separate tubes (see fig. 4).

The Wolffian duct, which, in the early embryo, carries the excretion of the mesonephros to the cloaca, forms eventually the body and tail of the epididymis, the ductus (vas) deferens, and ejaculatory duct in the male, the vesicula seminalis being developed as a pouch in its course. In the female this duct is largely done away with, but remains as the collecting tube of the epoöphoron, and in some mammals as the duct of Gärtner, which runs

down the side of the vagina to open into the vestibule.

The Müllerian duct, as it approaches the cloaca, joins its fellow of the opposite side, so that there is only one opening into the ventral cloacal wall. In the male the lower part only of it remains as the uterus masculinus, but in the female the Fallopian tubes, uterus, and probably the vagina, are all formed from it (fig. 4). In both sexes a small hydatid or vesicle is liable to be formed at the beginning of both the Wolffian and Müllerian duct, in the male these are close together in front of the globus major of the epididymis and are known as the sessile and pedunculated hydatids of Morgagni. In the female there is a hydatid among the fimbriae of the Fallopian tube which of course is Müllerian and corresponds to the sessile hydatid in the male, while another is often found at the beginning of the collecting tube of the epiofferon and is probably formed by a blocked mesonephric tubule. This is the pedunculated hydatid of the male. The development of the vagina, as Berry Hart (*Journ. Anat. and Phys.*, xxxv, 330) pointed out, is peculiar. Instead of the two Müllerian ducts joining to form the lumen of its lower third, as they do in the case of the uterus and its upper two-thirds, they become obliterated, and their place is taken by two solid cords of cells, which later become canalized and the septum between them is obliterated.

The common chamber, or cloaca, into which the alimentary, urinary and reproductive tubes open in the foetus, has the urinary bladder (the remains of the allantois) opening from its ventral wall (see PLACENTA; URINARY SYSTEM).

During development the alimentary or anal part of the cloaca is separated from the urogenital. According to F. Wood Jones, the anal part is completely shut off from the urogenital and ends in a blind pouch which grows toward the surface and meets a new ectodermal depression, the permanent anus, not being part of the original cloacal aperture, but a new perforation. This description is in harmony with the malformations occurring in this region.

The external generative organs have at first the same appearance in the two sexes and consist of a swelling, the genital eminence, in the ventral wall of the cloaca. This in the male becomes the penis and in the female the clitoris. Throughout the generative system the male organs depart most from the undifferentiated type and in the case of the genital eminence two folds grow together and enclose the urogenital passage, thus making the urethra perforate the penis, while in the female the clitoris is a small, fleshy, rounded eminence, the labium minoren, which is a part of the genital ridge. A fibromuscular cord is formed which stretches from the lower part of the testis to the bottom of the scrotum; it is known as the gubernaculum testis, and by its means the testis is directed into the scrotum. Before the testis descends, a pouch of peritoneum called the processus vaginalis passes down in front of the gubernaculum through the opening in the abdominal wall, which afterward becomes the inguinal canal, into the scrotum, and behind this the testis descends, carrying with it the mesonephros and mesonephric duct. These, as has already been pointed out, form the epididymis and ductus deferens. At the sixth month the testis lies opposite the abdominal ring, and at the eighth reaches the bottom of the scrotum and invaginates the processus vaginalis from behind. Soon after birth the communication between that part of the processus vaginalis which now surrounds the testis and the general cavity of the peritoneum disappears, and the part which remains forms the tunica vaginalis. Sometimes the testis fails to pass beyond the inguinal canal, and the term "cryptorchidism" is used for such cases.

In the female the ovary undergoes a descent like that of the testis, but it is less marked since the gubernaculum becomes attached to the Müllerian duct where that duct joins its fellow to form the uterus. Thus, the ovary does not descend lower than the level of the top of the uterus, and the part of the gubernaculum running between it and the uterus remains as the ligament of the ovary, while the part running from the uterus to the labium is the round ligament. In rare cases the ovary may be drawn into the labium just as the testis is drawn into the scrotum.

(F. G. P.)

REPTILES (*Reptilia*) is the name given to a class of vertebrates which hold a position in the animal kingdom intermediate between the amphibians and the birds, and the mammals. The group arose, perhaps in Lower Carboniferous times, from the Labyrinthodont Amphibia, and was already varied at the end of the Carboniferous. During Permian times the class branched out into many orders, one of which included the ancestors of the Mammalia, whilst from another the birds, crocodiles, Sphenodon, and perhaps the lizards and snakes arose. The tortoises are the descendants of another early group. In a recent survey by Nopcea, it is pointed out that, of the 125 families into which he divides the reptiles, only 18 are represented by living forms, whilst of the 19 orders only four are extant. The modern forms fall into the orders Crocodilia, including the crocodiles and alligators; the Squamata, the lizards and snakes, the Rhynchocephalia, represented only by the Tuatara lizard of New Zealand, and the Chelonla, the tortoises and turtles. These living forms are characterized as follows:

- (1.) The animal breathes air by lungs.
- (2.) The body temperature is variable.
- (3.) The skin is covered with horny scales formed by the epidermis.
- (4.) Fertilization is internal, and an egg, consisting of a yolk surrounded by albumen and contained in a shell, is usually laid and hatched by the heat of the sun or of decaying vegetation. In some cases reptiles are viviparous.
- (5.) In the brain the cerebral hemispheres are comparatively small. Their roof tends to become thinned and may be almost membranous. There is a well-developed hypophallium which becomes assimilated to the corpus striatum, losing the original stratification of the neurones. The mid-brain is relatively large and its roof forms a pair of large optic lobes.
- (6.) The olfactory organ has its surface increased by a simple tubular or concha, and there is a well-developed Jacobson's organ

FROM PHILOLOGICAL TRANSACTIONS OF THE BOTANICAL SOCIETY
FIG. 1.—SKULL OF THE EMBLOMORPHOUS AMPHIBIAN PALAEOGYRINUS;
(A) FROM ABOVE. (B) FROM THE LEFT SIDE

The posterior nares may be immediately below the external nostrils or may be carried back to the hinder end of the head.

The eyes are usually present, but may be hidden in burrowing forms. The retina normally contains both rods and cones, but may consist exclusively of either type. There is a pecten in the form of a folded sheet projecting into the vitreous humour.

The internal ear shows a more marked separation of *sacculus* and *utricle* than obtains in Amphibia, a lagena always occurs and is associated with a perilymphatic duct, in some cases so as to form a rudimentary cochlea. The tympanic cavity lies high up and the tympanic membrane is either superficial or lies at the end of a short external auditory meatus. The membrane is con-

nected to that closing the *fenestra ovalis* by a straight rod, whose inner end, the columella, is bony, whilst the outer half, the extracolumella, is often four-rayed, a short dorsal process being connected to the end of the paroccipital process and a ventral process often continued into the hyoid.

(7.) There is a well-developed tongue capable of free movement. The mid-gut has the usual structure; there is a cloaca and an urinary bladder of allantoic origin. The lungs are more elaborate than those of Amphibia and less than those of mammals.

(8.) The heart is three- or four-chambered, there being two auricles and a ventricle more or less completely divided into two. There is no bulbus; three arteries arise from the ventricle; of these one is the right systemic, another the pulmonary, whilst the third is the left systemic and both carotids. The posterior cardinals have both almost disappeared as such, the post-caval vein returning most of the blood from the posterior part of the animal to the heart. There is a coronary circulation.

(9.) The functional kidney in the adult is a metanephros discharging by a ureter into the cloaca. The ovary is often single and the egg always large. The oviduct is provided with glands which secrete albumen and a shell. A copulatory organ is usually present in the male, but is variable in structure.

(10.) The pre-sacral part of the vertebral column is usually less clearly divided into regions than in mammals and birds. There are two sacral vertebrae and a longer or shorter series of caudals. The atlas consists of a pair of neural arches, a single inter-centrum and a centrum which forms an odontoid, though it may not be fused to the axis. There is sometimes a pro-atlas. The vertebra of the rest of the column always consists of a neural arch and a centrum with inter-centra forming chevron bones in the tail. Small inter-centra may be present throughout the column. Ribs are usually present on all vertebrae except the posterior caudals; they may be single or double headed. A true sternum is usually present, connected to some of the dorsal ribs by sternal ribs.

The neural cranium is generally incompletely ossified, a good deal of the lateral walls anteriorly being membranous. It is often movably connected to the dermal bones of the skull roof and palate. There is a single occipital condyle, mainly basi-occipital but with contributions from the ex-occipital. A supra-occipital is present and articulates with the parietals. The inner ear lies within the opisthotic, usually fused with the ex-occipital, the pro-otic and the supra-occipital. An ossification in front of the pro-otic, in the side wall of the cranium, is absent in only two orders. There is an ossified basi-sphenoid, but the unossified pre-sphenoid is usually underlain by a para-sphenoid.

The dermal bones of the skull form a roof, which may be very incomplete or, indeed, absent, over the masticatory muscles, whilst the orbit is surrounded by a ring of bones which are continuous with the maxillae and nasals which enclose the anterior end of the head. In the palate the pterygoids are always large bones articulating with the basi-sphenoid and extending back to the quadrate. Pre-vomers and palatines are always present and ectopterygoids usually so. In many forms an epipterygoid is ossified. The lower jaw is complex, it articulates with the quadrate by an articular bone of endochondral origin, and at least five membrane bones contribute to its structure.

Fore and hind limbs are usually present, but either or both may be absent. The shoulder girdle consists of a pair of scapulae and "coracoids," both contributing to the glenoid cavity. There are generally clavicles and an inter-clavicle. The hand and foot are primitively pentadactyl, the fourth digit being the longest.

(11.) Segmentation of the egg is incomplete (meroblastic). No primitive streak is formed and a rudimentary archenteron with both roof and floor may be established. There is an amnion and an allantois, membranes developed for the protection, nutrition and respiration of the embryo.

Amphibian Ancestry.—The Amphibia, which were the ancestors of the reptiles, spent the greater part of their life in water, probably crawling on to land only to pass from one pool to another. They laid small eggs, which were fertilized after they had passed out from the body of the mother. These eggs de-

veloped into an aquatic larva which breathed by means of gills; subsequently, when this larva had reached a relatively large size, the gills were absorbed and the animal became dependent on the air for the main bulk of its oxygen. An aquatic animal may have, and in the case of the Amphibia did have, a soft skin which can only remain healthy if it be kept moist. Living Amphibia secure this condition by pouring out mucus and water from glands in their skin, which is therefore slimy. An animal which adopts this method has great difficulty in roaming far from water, the possibility of dying from desiccation being always present. Thus one of the first changes necessary to make an effectively terrestrial animal from an amphibian is to alter the character of its skin in such a way that it becomes water-tight, and has a dry outer surface. Such a change in a vertebrate is most readily achieved by thickening the epidermis and laying down keratin in its outer layers; continuation of this process leads to the formation of the horny scales of reptiles, which are made by localized patches of skin exceptionally active in the production of keratin. As such a skin does not require to be kept moist, glands are very poorly developed in the skin of reptiles.

During the transition from water to air the sense organs necessarily undergo great modifications. The olfactory organ, which had become adapted to the relatively large amounts of odorous substances which could come to it in solution in water, had to be made capable of recognizing the much smaller amounts brought to it as vapour through the air. In the intervening stage of the Amphibia the nose becomes double, one part of it, Jacobson's organ, functioning in water, the rest in air. When the reptiles became completely terrestrial, Jacobson's organ took on the new function of smelling the material lying in the mouth, and the rest of the organ became the normal organ of smell.

The eye, adapted for focussing objects under water, has to be so

FROM PHILOSOPHICAL TRANSACTIONS OF THE ROYAL SOCIETY

FIG. 2.—SKULL OF THE CROTALUS SEYNOURENSIS: (A) FROM ABOVE, (B) LEFT SIDE

changed in its proportions as to see its surroundings through air.

That part of the ear whose function is to determine the position of the animal with respect to gravity and to recognize changes in position, can remain unaltered, but the lagena, which, with its associated structures, the columella, middle ear and tympanic membrane, is concerned with hearing in the ordinary sense, necessarily undergoes changes on account of the very different specific gravity of the mediums, water or air, through which sound waves come to it.

Aquatic Amphibia have, in common with fish, a special sense,

whose organ is the lateral line, which is concerned with the recognition of movements in water; with the transition to land this sense is entirely lost.

Any animal living in water is so nearly floating that the proportion of its weight which has to be supported by the limbs is extremely small. As soon as it comes out of water practically the whole of its weight falls on the legs. Thus the skeleton and musculature necessarily become more powerful.

The most serious changes, however, are those in the mode of reproduction. An amphibian which lays its eggs in the water can fertilize them there, but a terrestrial animal can only lay an egg

FIG. 3.—PALATE OF THE EMBOLOMEROUS AMPHIBIAN, BAPHETES

if it is included in a shell which will protect it from mechanical injury and, a matter of more importance, from drying up. Such a shell cannot be perforated by a spermatozoan, so that fertilization must take place within the body of the mother before the shell is formed. The uro-genital organs of both sexes have to be so modified as to allow this to take place, and the oviduct of the female must be provided with the glands that are necessary for the formation of the shell.

The amphibian egg may be comparatively small; it only needs to contain a food supply sufficient to maintain the developing embryo to a stage when it hatches as a small larva capable of feeding on the abundant food present in the water in which the egg was laid. The animal, which hatches from an egg laid on land, must make its appearance at a stage in development when it can maintain itself under conditions similar to those in which its parents live. The time taken in reaching such a stage of development is considerable, and the egg included in its shell has no opportunity of obtaining food or water from outside. Thus, when laid, the egg must contain everything necessary for the development of the embryo up to the time of hatching.

The reptile ovum, the yolk of the egg, contains the great bulk of the food materials, whilst the albumen, the white which surrounds it, is mainly a water store. The egg-shell is porous and transmits gases. The character of the development of the large egg is necessarily modified by its bulk, much of the yolk remaining undivided into cells until it is absorbed and converted into part of the animal's own tissues. Special embryonic membranes, the amnion and allantois, are produced during the development for the protection of the embryo and for its nutrition and respiration, the allantois serving also as a reservoir for the nitrogenous waste products produced by its metabolism.

The great majority of these changes, including all those which are of the greatest importance, cannot be determined from fossil material, and we are driven back for the discrimination between fossil reptiles and fossil amphibians to the use of technical points mainly of little functional importance to the animal. The break between the Amphibia and Reptilia was regarded by Huxley and other early workers as the most important in the vertebrate phylum; such contrasted terms as Ichthyopsida and Sauropsida, Anamniota and Amniota emphasize its importance. None the less we now know an animal, *Seymouria*, from the lowest Permian of Texas, which is regarded by one group of students as an amphibian and by another as a reptile. As the osteology of this

animal is very completely known, the doubt which exists as to its systematic position illustrates vividly the completeness with which the gap between these two divisions has been bridged.

Seymouria is a small animal about 2 ft. in length, with a comparatively small head, no visible neck, a somewhat stumpy body, and a short tail. The limbs were very muscular, but short. The hands and feet were placed far away from the middle line, and the stride was exceedingly small. Each limb has five digits.

The skull of *Seymouria* consists of two parts, which could have easily been separated from one another. These are the brain case, made of bones which have replaced the cartilage which existed in the embryonic skull, and a superficial coating covering the whole outer surface of the head (except for the nostrils, orbits and pineal foramen), and the roof of the mouth, made of bones which have developed in the lower layers of the skin. The pattern formed by these dermal bones is identical with that which is found in the more primitive Labyrinthodont Amphibia, and is important, because from it the structure of the corresponding parts of the skulls of all other reptiles can be derived, by a process of reduction. The palate of *Seymouria* is, in essence, identical with that of an Embolomorous Labyrinthodont. The brain case, however, differs somewhat from those of the Amphibia. For example, the single occipital condyle is convex instead of being concave, and there is a large fenestra ovalis leading into the ear which does not exist in the Embolomere. There are also variations in other details of the structure of the otic region. In the lower jaw, *Seymouria* is identical with an amphibian, but the vertebral column is very different.

In the amphibian the first vertebra articulates with the condyle by a disc-shaped inter-centrum followed by a disc-shaped centrum, of the same character as those which succeed it. In *Seymouria* the rounded condyle articulates below with a concavity on an inter-centrum which represents only the lower half of that of the amphibian, and with facets carried on the lower ends of the two halves of the neural arch. The centrum of the atlas is a curious trefoil-shaped bone which fits in between the three elements which articulate with the condyle; this arrangement is completely reptilian. The structure of a vertebra from the middle of the back of *Seymouria* is quite peculiar. There is a small cylindrical centrum separated from the next by an inter-centrum having the shape of half a disc. The neural arch is enormously heavy, it articulates with the centrum alone and the pre- and post-zygophyses are produced laterally as masses of bone which overhang the much smaller centrum. The articulating faces are quite flat and placed horizontally, so that the back, although free to move from side to side, must have been extremely stiff dorso-ventrally.

Vertebrae of this type are known in no amphibian, but in a less exaggerated form occur in many of the more primitive reptiles. It is reasonable to believe that they were evolved as a clumsy method of giving that stiffness to the back which is necessary to an animal which, living in air, has to support the whole of its weight. The ribs of *Seymouria* do not differ essentially from those of Labyrinthodonts. The limb girdles and limbs are of the amphibian pattern except in one or two details, e.g., the occurrence of an ent-epi-condylar foramen piercing the humerus, and the number of the phalanges, which is two, three, four, five, three, the characteristic reptilian number.

Thus it is possible to be in doubt whether an extinct animal whose skeleton is completely known is an amphibian or a reptile, the break between the two being completely bridged so far as the skeleton is concerned. From a skeleton similar to that of *Seymouria* it is possible to derive those of all later reptiles, and in this way, by sorting out separate evolutionary lines to establish a classification which may express not only differences of structure existing between the animals contained in it, but something of their phylogenetic relationships.

Evolutionary Development.—The reptiles, as a whole, with a few doubtful exceptions, divide into two great branches, the mammal-like reptiles and the rest. The differences between the members of these two groups are to be found mainly in the structure of the brain case and the back of the skull. In all the

mammal-like reptiles the inner ear lies in the lower part of the side wall of the brain case, the brain extending far above it, while in all other reptiles the ear extends throughout the whole of the side wall of the cranium and is not exceeded in height by the brain. In *Seymouria* the tympanic membrane is stretched across a notch on the outer surface at the back of the skull; in the mammal-like reptiles this notch is destroyed, so that the occipital surface of the skull is flat and the tympanic membrane, if it exists at all, lies ventrally in the neighbourhood of the hinder end of the lower jaw, to one of those elements it is attached. In the remaining reptiles the tympanic or otic notch is preserved, bounded above by a special process of the squamosal or tabular bone, and by the free distal extremity of the paroccipital. The tympanic membrane, when present, lies high up on the side of the head, far removed from the lower jaw. In the mammal-like reptiles the stapes is attached directly to the quadrate bone, while in the others it is continued by an extra columella which is inserted into the tympanic membrane.

It is customary to recognize a primitive group of reptiles, the Cotylosauria, which includes the most primitive members of each division of the reptiles. The animals included in it agree with *Seymouria* in that the dermal bones of the outer surface of the skull form a continuous sheet, perforated only by the nostrils, orbits and pineal foramen. This group is restricted to Permian and Triassic time, and its members thus possess very primitive limbs and limb-girdles. They are usually devoid of a neck, the shoulder-girdle lying immediately behind the head. The back is short and the vertebrae of which it is composed have very massive neural arches which articulate with one another by horizontal surfaces. The centra are perforated and transmit a continuous notochord. There is usually a series of intercentra throughout the column. The shoulder girdle has three bony elements, the scapula, procoracoid and coracoid in each side of the cartilage girdle; all of them contribute to the glenoid cavity. Cleithra are often present, and clavicles and large inter-clavicles are universal. The fore leg is short and massive, the humerus projecting out at right angles to the animal's body and lying in a plane parallel to the ground. It can only be moved backwards and forwards, and is incapable of rotation. The elbow joint is flexible, so that the fore arm has much freedom of movement. The hand has five fingers, the number of the phalanges being 2, 3, 4, 5, 3, in the digits from 1 to 5. The pelvis consists of an ilium, pubis and ischium on each side, these bones meeting one another in continuous sutures, so that the whole structure is "plate-like." The hind limb projects out laterally and the knee is relatively inflexible; it could be stretched out straight, but, in many cases, could not be closed even to a right angle. The foot has five toes with a digital formula 2, 3, 4, 5, 4.

This super-order can be divided into three sub-groups, as follows:—(A.) *Seymouria morpho*, primitive forms represented by three genera, *Solenodonosaurus*, from the Upper Carboniferous of Czechoslovakia; *Seymouria*, from the basal Permian of Texas, and *Kotlossia*, from the Upper Permian of Russia, which may not properly belong to the group.

These animals possess skulls which very greatly resemble those of the Embolomerous Amphibia. (See AMPHIBIA.) These skulls have a narrow otic notch differing from that of all other reptiles; the neural cranium is peculiar in that the powerful paroccipital processes which arise from the sides of the brain case extend outwards and upwards to support the tabular bones. The basioccipital, together with the exoccipitals, form a rounded condyle. There are well marked basispinothal tubera and the basipterygoid processes of the basispinothal are short, and in *Seymouria* support the pterygoid, not directly, but through the intervention of the epityergoid. The parasphenoid is short and narrow. The palate is almost completely roofed with bone, there being small palatal nostrils and sub-temporal fossae in addition to a very conspicuous inter-ptyergoid vacuity. The palatine bears a large tusk, the marginal teeth in the upper jaw form a uniform unbroken series and exhibit an indefinite replacement. The lower jaw is built up from nine bones, dentary, splenial, post splenial, angular, sur-angular on the outer surface, the series of three coronoids between the pre-

articular and dentary, and an articular bone which, unlike that of all contemporary Amphibia, is not a mere part of the sur-angular. With this exception, the jaw is identical with that of a Labyrinthodont.

The vertebral column is massive, there is no distinction of neck, trunk, and lumbar region, all the vertebrae from the atlas back to the sacrum bearing two-headed ribs; there is one sacral vertebra. In the shoulder girdle a coracoid is absent, the lower part of the primary structure being ossified entirely as a pre-coracoid. The glenoid cavity has the characteristic screw-shaped form of the early Tetrapod. The humerus is an extraordinary bone, nearly as wide as it is long, while the fore arm is short. The hand is short and broad, the five fingers ending in small claws.

The pelvis is plate-like, the pubes and ischia being exceptionally large elements; the femur, short, broad and unusually massive, exactly resembles that of contemporary Amphibia. The fibula is widened distally, and the tarsus is remarkable among reptiles in possessing three bones in its proximal row, the intermediate being still separate from the tibiale. The foot is five toed, with the normal formula.

The mammal-like members of the Cotylosauria belong to the group (B.) Captorhinomorphs. This group includes a considerable number of reptiles, all of Lower Permian age, which vary a good deal in their general structure. The most typical are Captorhinus and its descendant, Labidosaurus. These animals are comparatively small, with no neck, rather long bodies and not excessively long tails. They had a straddling gait, the ventral surface touching the ground and the feet being placed well away from the side of the body. The head is pointed, the face in front of the eyes narrow, while the temporal region is wide. The skull is completely roared and there is no trace of an otic notch, the head having a square cut appearance posteriorly. The brain case seems to be high, and is loosely connected with the rest of the skull by the summit of the supraoccipital and the ends of the paroccipital process. The stapes is very massive and extends from the fenestra ovalis, which is placed below the level of the brain, to the quadrate to which it is attached.

The lower jaw differs from that of *Seymouria* by a lateral compression of its hinder half, and by the reduction of the coronoids to one.

The vertebral column is characterized by the massiveness of the neural arches and the obsolescence of the neural spines. The

FIG. 4.—SKULL OF THE COTYLOSAUR SEYMOURIA (AFTER WATSON)

centra are small and perforated, the intercentra much reduced. All the ribs are single-headed. The remainder of the skeleton does not differ materially from that of *Seymouria*, which has been described above.

The earliest and most primitive members of the group of mammal-like reptiles belong to the order Pelycosauria. The most primitive members of this group, such as Varanosauros and Mycterosaurus are small, rather slender animals, with elongated pointed heads. They had no visible neck, the shoulder girdle being placed behind the skull. The body was long and the

tail even longer. Their skulls differ from those of the Captorhinomorphs most obviously in that the dermal roof is no longer complete, but is perforated by a large lateral vacuity which is bounded by the jugal, postorbital and squamosal bones. This opening serves to give room for the thickening of the masticatory muscles, which necessarily occurs when they are shortened so as to close the mouth.

Another important difference is that the supraoccipital bone becomes so widened that, with the overlying interparietal and tabu-

FIG. 5.—SKULL OF THE CALYMENOSAUR, DIADECTES; (A) LEFT SIDE WITH LOWER JAW, (B) FROM ABOVE

lar, it forms a plate on the hinder surface of the skull, which reduces the post-temporal fossae to very small proportions.

The only important changes in the post cranial skeleton are that the neural arches become light and narrow, the neural spines high, and the articulation faces of the zygapophyses are obliquely placed.

From such animals a series of short evolutionary lines arose, which led to the development of some extraordinary forms in which the neural spines from the head to the root of the tail become immensely elongated, and, in some cases, provided with lateral processes like the yard-arm of a ship. These animals, Dimetrodon and Naosaurus, must have been of grotesque appearance, one with a huge head with great piercing teeth, the other with a very small head with crushing dentition, each with a crest, as high as its own length from head to the root of the tail. Animals so specialized naturally had only a short range in time, they only occur in Lower Permian rocks, but the latter ranged from Czechoslovakia to Texas.

More conservative members of the group gave rise to a number of reptilian orders whose remains have been found in the Middle and Upper Permian rocks of Europe and South Africa, and in the Trias of South Africa, Asia and North America. The most important of these orders, the Theriodontia, included the ancestors of the mammals, and its members exhibit a series of stages which seem to bridge the structural gap between a Pelycosaur and a mammal very completely.

Some of these changes are illustrated by a comparison of the skulls of *Scymnognathus* and *Cynognathus*.

The skull of *Scymnognathus*, a Gorgonopsid, differs from that of a primitive Pelycosaur in that in it the whole head is flattened, the temporal vacuity, instead of facing laterally, is directed upward and is greatly increased in size; this change implies that the muscles which close the mouth had changed, an originally rather simple mass splitting up into pterygoid, temporal and

masseter muscles. In order to give room for this powerful development the side of the roof of the skull, formed by the jugal post-orbital and squamosal, is bowed out, with the result that the quadrate and quadrato-jugal, being fixed in position by their articulation with the lower jaw, become detached from the side of the head and remain inserted in a depression on the front face of the squamosal, within the temporal vacuity. At the same time they are somewhat reduced in size.

The enlarged masticatory muscles require a more extensive area of attachment on the lower jaw, to provide which the upper and hinder end of the dentary becomes free and grows upward. At the same time, the hinder half of the jaw, composed of the surangular, angular, articular and prearticular bones, become converted into a thin sheet by a lateral compression, and the lower border of the angular is notched, a special lamina of the bone being reflected over the outer surface of its posterior part. To this reflected lamina the lower edge of the tympanic membrane seems to have been attached.

The palate, though it still has the posterior nares placed far forward, is advanced because it is very much vaulted, owing to the downgrowth of the maxillae on each side of it. Posteriorly, the pterygoids, with a parasphenoid held between them, form a narrow girder which connects the basisphenoid with the anterior part of the palate.

The stapes still articulates with the quadrate. The brain case is incompletely ossified in front of the point of exit of the fifth cranial nerve. The branches of that nerve pass on each side of the rod-like epipterygoid, and the cerebral hemispheres are enclosed in a single ossification homologous with the sphenethmoid of a frog.

Cynognathus has advanced beyond *Scymnognathus* in that the face has become deeper and more rounded, and the nostrils larger. The temporal vacuity has enlarged so that it is bounded above by the parietal, and this bone is drawn up into a deep sagittal crest which allows of longer temporal muscles. The quadrate and quadrato-jugal have become greatly reduced in size, but retain their position and function.

The coronoid process of the dentary has increased enormously, and now overlaps the rest of the lower jaw so greatly that it has nearly, but not quite, acquired an independent articulation on the squamosal.

The hinder part of the lower jaw, though still retaining all its constituent bones, has become so small that it seems inadequate to resist the very great stresses to which it might be subjected during feeding. The reflected lamina of the angular is still present in the form of a slender downturned process.

The palate has changed greatly, the original roof of the median area is still present in part, but it is concealed from view by a secondary palate exactly like that of a mammal, which is formed by ingrowths from the maxillae and palatines. By this change the posterior nares are driven so far backward that they open behind the cheek teeth, and the animal became capable of breathing while the mouth was full of food undergoing mastication. The ectopterygoid is greatly reduced, and the posterior part of the pterygoid, the quadrate ramus, has vanished altogether, its place being taken by a process which grows backward from the root of the epipterygoid.

The side walls of the brain case have become bony by a widening of the upper end of the epipterygoid, now recognizable as the homologue of the mammalian alisphenoid. This arrangement involves the inclusion in the cranial cavity of a space, the cavum epiptericum, which in most other reptiles lies outside the cranium. By a continuation of changes in the same direction as those which converted a Gorgonopsid such as *Scymnognathus* into the Cynodont *Cynognathus*, a primitive mammalian structure is easily reached.

The face changes little, a disappearance of the internarial processes throws the bony nostrils into one, the prefrontal and post-orbital disappear, and the orbit becomes confluent with the temporal fossa.

Further growth of the dentary leads to the development of a new temporo-mandibular joint between that bone and the squa-

FIG. 7.—SKULL OF PLACODUS: (A) LEFT SIDE, (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT (AFTER BROLI)

upper surface of the skull, the latter overhanging the otic notch. Stapes terminating freely in the otic notch. Brain case long, fenestra ovalis placed at about the middle of its height. Intercentra usually present. Two to four sacral vertebrae. Shoulder girdle with a scapula alone or with three cartilage bones. Cleithrum usually present. Humerus always with expanded ends but often of advanced structure. Ilium sometimes backwardly directed.

Lower Permian to Middle Trias. Families: *Diadectidae*, *Parasauridae*, *Procolophonidae*.

Super-order Theromorpha (or Anomodontia). Mammal-like reptiles. Reptiles in which the temporal region of the skull is perforated by a single vacuity, bounded primitively by the postorbital and squamosal, but enlarging so that the parietal and jugal also enter its borders. Cranium short and high behind the incisura prootica, fenestra ovalis below the level of the base of the brain. Stapes articulating with the quadrate. The lower jaw, and especially its hinder end, laterally compressed, the angular in all except, perhaps, the most primitive forms, with a notch in its lower border.

A pro-atlas present, the neural arch of the atlas usually a pair of bones, which, with the intercentrum, rest on the anterior end of a trefoil-shaped odontoid. Vertebrae with slender neural arches with oblique articular faces, centra notochordal or deeply amphicoelous. Intercentra usually present, at any rate in the cervical region, ribs always two-headed anteriorly, usually single-headed posteriorly. An ossified sternum sometimes present, abdominal ribs present as slender rods in primitive forms. Pectoral girdle with scapula, precoracoid and coracoid in all forms (except one, *Varanops*), clavicle with expanded lower end, and interclavicle a wide flat sheet. Cleithra usually present, but small. Pelvis very variable, plate-like in primitive forms, with an obturator foramen in later types. Ilium, directed forwards, vertically, or backward. Two to seven sacral vertebrae. Limbs exhibiting all stages of advance from primitive cotylosaur-like organs to a pro-mammalian condition. Digital formula primitively 2, 3, 4, 5, 3 or 4 reduced to 2, 3, 3, 3, 3 in later forms.

Order 1. Pelycosauria. Primitive Theromorpha in which the pterygoids articulate with the basipterygoid processes of the basisphenoid by a movable joint. The quadrate is relatively large and the quadrato-jugal forms part of the lateral surface of the skull. The shoulder girdle has a screw-shaped glenoid cavity shared by the scapula, coracoid and precoracoid, and the limbs are primitive. The pelvis is plate-like.

Upper Carboniferous and Lower Permian. Families: *Poliozaridae*, *Ophiacodontidae*, *Sphenacodontidae*, *Edaphosauridae*, *Caseidae*, *Bolosauridae*, *Palaeohatteridae*.

Order 2. Deinocerophalia. Theromorpha in which the pterygoids are attached to the basisphenoid by an immovable joint. The basioccipital and basisphenoid are produced downward below the occipital condyle as a thick sheet of bone. The quadrate is unreduced and the quadrato-jugal is on the lateral surface. The shoulder girdle in early forms has the glenoid cavity borne only to a very slight extent on the precoracoid, but it is screw-shaped; in later forms this structure disappears and the glenoid cavity is restricted to the scapula and coracoid. The limbs are of modernized type. The pelvis is plate-like, the ilium being attached to four sacral ribs.

Middle Permian. Families: *Taphroscaphidae*, *Titanosuchidae*.

Order 3. Dromosauria. Small Theromorpha in which the facial region of the skull is very short, the temporal fossa is bounded above by the postorbital and squamosal and the zygomatic arch is reduced to a narrow rod so that the quadrate and quadrato-jugal project below it. Shoulder girdle with the glenoid cavity on the scapula and coracoid, precoracoid large. No cleithra. Pelvis plate-like. Limbs very long and slender, digital formula 2, 3, 3, 3, 3.

Upper Permian. One family only.

Order 4. Dicynodontia (or Anomodontia). Theromorpha in which the preorbital part of the skull is very short, whilst the temporal vacuity is greatly enlarged. The latter is bounded above by the postorbital and squamosal. The quadrate and quadrato-jugal are reduced, and rest in a recess in the front face of the lower end of the T-shaped squamosal, which is widely expanded laterally so as to form a sheet in the plane of the occipital surface. The pterygoids are rigidly fixed to the basisphenoid, and are not produced into transverse flanges. The premaxillae are fused and toothless, the maxillae may have a large canine or a series of small cheek teeth, or both, or be toothless. A horny beak like that of a tortoise was always present. The articular of the lower jaw always has the unique feature of a convex articular surface. Intercentra are absent except in the atlas and axis. The tail is short. The glenoid cavity is entirely, or almost entirely, restricted to the scapula and to the coracoid. There is an acromion on the scapula which also shows the beginnings of a mammal-like scapular spine.

There is an obturator foramen in the pelvis. The limbs are short and powerful, the track wide, and the digital formula 2, 3, 3, 3, 3.

Upper Permian to Middle Trias. Division into families not yet carried out.

Order 5. Theriodontia. Theromorpha in which there is a differentiation of the dentition into incisors, canine and cheek teeth. The face is usually long, the temporal fossa, short in primitive forms,

elongated in the more advanced types, the parietal entering into its border.

Quadrate and quadrato-jugal, fused, much reduced and carried in a recess on the front face of the squamosal.

Pterygoids forming great transverse flanges, behind which they suddenly contract to form a narrow girder extending back to the basi-sphenoid. Palate at first with the large posterior nares placed anteriorly, becoming vaulted, the air passage being finally cut off from that for the food by a secondary palate. The dentary, always extending above the surangular, in a free coronoid process. Limbs and their girdles variable.

Sub-order 1. Gorgonopsia. Primitive Theriodonts, with the postorbital and squamosal meeting above the temporal fossa. Single occipital condyle: No sub-orbital vacuities. No secondary palate. Scapula without acromion, plate-like pelvis, digital formula (of hand) 2, 3, 4, 5, 3.

Upper Permian.

Sub-order 2. Cynodontia. Advanced Theriodonts, with the parietal entering the temporal fossa. No sub-orbital vacuities. A secondary palate. Pair of exoccipital condyles. Scapula with acromion. Pelvis with an obturator foramen. Limbs modernized, digital formula 2, 3, 3, 3, 3.

Top of the Permian and Lower Trias.

Sub-order 3. Theroccephalia. Primitive Theriodonts with large temporal vacuities into whose border the parietal always enters. Large sub-orbital vacuities. No secondary palate or vaulting of the mid line of the anterior part of the palate. Single occipital condyle.

Upper Permian.

Sub-order 4. Bauriomorpha. Advanced Theriodonts, with the parietal forming part of the temporal fossa. Large sub-orbital vacuities, a secondary palate. Single occipital condyle.

Lower to Upper Trias.

Order 6. Thalattosauria. A group of marine reptiles, still incompletely known, but perhaps allied to the Pelycosauria. If so interpreted they may be defined by the following characters.—Skull with a very elongated face formed by the maxillae and premaxillae, nostrils dorsal and immediately in front of the large orbit, nasals small. The large temporal fossa is entirely lateral and is bounded above by the postorbital and squamosal. Quadrate large. A supratemporal present. Parietals short and wide. Vertebrae with biconcave centra which are short cylinders, ribs single-headed. Scapula and coracoid incompletely ossified. Humerus with expanded ends and a twisted shaft. Radius and ulna short flattened bones.

Upper Trias.

Super-order Archosauria (Diapsosauria). Reptiles in which the temporal region of the skull is perforated by two vacuities, the upper of these, the supratemporal fossa is bounded by the parietal, supratemporal, squamosal and postorbital the lower, the infratemporal fossa lies between the postorbital squamosal, quadrato-jugal and jugal bones.

The brain, at any rate in the later forms, is completely enclosed by bone, a pair of latero-sphenoids surrounding the cerebral hemispheres and stretching back to have a suture with the pro-otic. The epityergoid forms no part of the wall of the cranial cavity. The fenestra ovalis lies half way up the wall of the brain case. There is always a distinct neck, often of eight vertebrae.

The pectoral girdle contains a scapula and precoracoid on each side, the true coracoid never appearing. Cleithra are never present. The sternum usually ossifies from a pair of centres. The limbs are never of the primitive Cotylosaurin character, and are often very highly modified. The digital formula is 2, 3, 4, 5, 4 or 3.

Order 1. Thecodontia. Primitive Archosauria in which a supratemporal, tabular and interparietal may be present in the skull. A preorbital vacuity may be present or absent. The ribs may have one or two heads and a sternum if ossified is paired.

Clavicles and an interclavicle are always present, the pelvis is plate-like, and there are only two sacral vertebrae.

Upper Permian to Upper Trias. Families: *Eosuchidae*, *Phytosauridae*, *Pseudosuchidae*, *Erythrosuchidae*, *Erpetosuchidae* and others not yet defined.

This order is, in a sense, artificial, it includes the ancestors, for the greater part unknown, of the remainder of the orders of

Archosauria, and in addition contains a number of animals which belong to short-lived unsuccessful side branches.

Order 2. Crocodilia. Archosaurs usually of medium or large size, and adapted more or less completely to an aquatic habit. The skull is characterized most clearly by the fact that the quadrate is very large, and lies at a very low angle with the horizontal. The wedge-shaped otic cavity so formed is closed behind by a downgrowth of the squamosal, which, with the overlapping "exoccipital" reaches the quadrate. The tympanic membrane lies some distance below the outer surface, and the external auditory meatus can be closed by a muscular flap. The elongated face is chiefly formed by the maxillae, the external nostrils, usually confluent in the bony skull lying quite anteriorly. There is always a secondary palate, the choanae lying posteriorly between the palatics or pterygoids. The vertebrae are amphiplatean or procoelous, the ribs double-headed throughout the presacral part of the column, the dorsal ribs articulating entirely with the neural arch. The coracoid is elongated, clavicles are absent; and the sternum is unossified. The ilium is a small bone supported by two sacral ribs, and the pubis is excluded from the acetabulum.

The hand is five-fingered, the foot has the fifth toe reduced to a stump of its metatarsal.

Lower Jurassic (Upper Trias) to Recent. Families: *Telosauridae*, *Metriorhynchidae*, *Dryosauridae*, *Goniopholididae*, *Libyscosuchidae*, *Pholidosauridae*, *Stomatosuchidae*, *Gavialidae*, *Crocodylidae*.

It is not improbable that the *Crocodylia* sprang from the family *Erpetosuchidae* of the order Thecodontia.

Order 3. Saurischia (Deinosauria parts) Archosauria, with a well-developed preorbital vacuity. The neck is sharply marked off from the trunk. The presacral ribs are two-headed, and the dorsal ribs articulate only with the neural arch. Clavicle and interclavicle are lacking, the coracoid is short. There are three or more sacral vertebrae. The pubis and ischia form diverging rods, primitively the pelvis is plate-like, but the bones separate from one another in later forms. The acetabulum is perforate. The fore limb is shorter than the hind, and the femur moves in a plane parallel to the animal's length. The body is thus held well above the ground, and the animal is often bipedal.

Sub-order Theropoda. Carnivorous Saurischia, in which the dentition consists of a single series of the codont, laterally compressed teeth in the premaxillae and maxillae. The cervical vertebrae may be opisthocoelous. The fore limb is often very much smaller than the hind, and the animals are usually bipedal. The hand tends to be reduced to the first three fingers, which are provided with powerful claws, and the foot becomes functionally tridactyl and symmetrical about the third toe.

Middle Trias to Upper Cretaceous.

Families: *Hallopidae*, *Podokosauridae*, *Coeluridae*, *Compsognathidae*, *Ornithomimidae*, *Plateosauridae*, *Zanclodontidae*, *Archisauridae*, *Megalosauridae*, *Spinosauridae*.

Sub-order Sauropoda. Herbivorous Saurischia, usually of gigantic size. The skull is extremely small, and the dentition feeble. The cervical and many or all the dorsal vertebrae opisthocoelous. Accessory articulating faces are developed in the neural arch of the dorsal vertebrae. The dorsal centra are excavated laterally, so that they may be reduced to mere shells of bones.

The animals are quadrupedal, and walk on the ends of the metapodials, both feet are five toed, but some of the digits have a reduced number of phalanges and most lack claws.

Middle Jurassic to Upper Cretaceous. Families: *Cetiosauridae*, *Allantosauridae*, *Camarasauridae*, *Diplodocidae*, *Titanosauridae*.

Order 4. Ornithischia (Deinosauria pars). Archosauria of herbivorous diet. The preorbital fossa is usually small or absent, the nostrils very large. The quadrate, unless secondarily fixed, is movable, a spherical head on its upper extremity resting in a cup in the squamosal. Premaxillae usually toothless, and covered with a horny beak, which opposes a similar structure carried by a special predentary bone in the lower jaw. Posterior end of the dentary raised into an upstanding coronoid process. The pubis bifid, a prepubic process stretching forward along the belly, and a posterior part passing downward and backward parallel to the

FIG. 8.—SKULL OF THE GORGONOPSID REPTILE, SCYMNONGNATHUS
A. Right side, B. from above, C. from below, D. coolup

ischium. Ilium elongated anteroposteriorly. Acetabulum perforate. Fore leg shorter than the hind, the animal being often bipedal. Hand usually pentadactyl, foot often tridactyl.

Rhætic to Upper Cretaceous.

Super-family Ornithomorphidae. Families: *Hypsilophodontidae*, *Camptosauroidae*, *Ignanodontidae*, *Trachodontidae*. **Super-family Stegosauridae.** Families: *Scelidosauridae*, *Stegosauridae*, *Acanthophoridae*, *Polacanthidae*. **Super-family Ceratopsidae**, with one family.

Order 5, Pterosauria. Archosauria fully adapted for flight. The vertebrae and many long bones are hollow and, where occupied by air sacs, arising no doubt, like those of birds, by extension of the bronchi. Skull elongated, triangular in plan, and peculiar in that the quadrato-jugal excludes the jugal from the border of the infra temporal fossa. Teeth may extend throughout the jaws, be restricted to their anterior ends, or be absent altogether.

Cervical vertebrae large, procoelous, and very freely movable, head carried nearly at right angles to the neck. Dorsal vertebrae small, sometimes largely fused, sacrum of four to six vertebrae, tail either very short or greatly elongated and quite stiff.

Scapula and coracoids elongated slender rods, the latter articulating with a large shield-shaped sternum. Clavicular arch absent. Ilium long, pubis and ischium fused with it and with each other, not meeting in a median symphysis. Prepubic bones present. Fore limb supporting a wing, which is formed by a fold of skin arising from the side of the body and stretched between the upper arm, fore arm and greatly extended fourth finger, and the hind leg. Fingers one to three, present and clawed.

Sub-order Rhamphorhynchoidae. Pterosaurs, with a long tail, wing metacarpal short, fifth toe well developed.

Upper Trias? Lower Lias to Upper Jurassic.

Sub-order Pterodactyloidea. Pterosaurs, with a short tail, wing metacarpal long, and fifth toe reduced or absent.

Upper Jurassic to Upper Cretaceous. Families: *Pterodactylidae*, *Ornithocheiridae*.

The birds, class Aves, are certainly descendants of Archosaurian reptiles; had the group become extinct in Cretaceous time it would be regarded as an order equivalent to those listed above.

The remaining reptilian orders cannot usefully be grouped into super-orders.

Order Rhynchocephalia. Reptiles in which the temporal region is perforated by two fossae; the supratemporal fossa seems to differ from that of Archosauria in that the post frontal enters into its margin, whilst the infratemporal fossa differs by the exclusion of the quadrato-jugal.

The preorbital part of the skull is short, and there is no pre-orbital opening. The fenestra ovalis is placed high in the skull. The dentary bears a single series of acrodont teeth which bite into a groove between the similar teeth on the maxilla and palatine, so that with use they acquire a wedge-shaped section. The vertebrae have amphicoelous centra, and all the ribs are single-headed. An unossified sternum is present. The shoulder girdle includes scapulae, precoracoids, clavicles and an interclavicle.

The pelvis has an ilium attached to two sacral vertebrae and directed downward in front. The pubis and ischia are plate-like in primitive forms, but diverge widely in later times. The limbs are pentadactyl, and the fifth metatarsal has a hook-shaped upper extremity.

One group of Rhynchocephalia, the *Champsosauridae*, became highly adapted to an aquatic life in estuaries.

Middle Trias to Recent. Families: *Rhynchosauridae*, *Sauronodontidae*, *Sphenodontidae*, *Champsosauridae*.

Order Squamata. (The following account does not include the characters of the reptile *Pleurosauros*, which is, perhaps, a member of the order.)

Reptiles in which the dermal roof of the temporal region is so far reduced that only a single temporal arcade, or none at all, remains. The quadrate is thereby freed so that it can move, its rounded head articulating with one or two bones which are connected with the parietal. If two bones be present the inner is firmly applied to the front face of the posterior wing of the parietal, and rests against and may even be firmly fixed by suture to the front face of the end of the paroccipital process. This bone is either the supratemporal or squamosal, or, very improbably, tabular. The outer bone is fixed to the lateral surface of the inner, often overlapping it on to the parietal; it stretches forward as the hinder part of the temporal arcade, and meets the postorbital and sometimes the jugal. This bone is either the squamosal or quadrato-jugal. In the palate the pterygoid no longer reaches the prevomers, and the whole is often very lightly constructed.

The vertebrae are usually procoelous, but may be amphicoelous; there are two sacrales or none. Ribs are single-headed throughout. The shoulder girdle, if present and fully developed, consists of scapulae and precoracoids, often enlarged and notched or fenestrated, clavicles, an interclavicle and a sternum. The pelvis has a forwardly and downwardly directed ilium, the pubes and ischia are divergent rods. The limbs are pentadactyl primitively, but may be reduced or absent.

Sub-order Lacertilia (Lizards). Squamata in which a temporal arcade is usually present, and in which the two ram of the lower

jaw are connected suturally at the symphysis. An epipterygoid is present in the normal position and the anterior part of the brain case is very little ossified. The pterygoid articulates with the basipterygoid process of the basisphenoid.

Upper Jurassic to Recent.

Division Ascalabota.

Section Gekkota.

Families: *Ardeosauridae*, *Gekkoniidae*, *Uroplatidae*, *Section Iguania*. Families: *Iguanidae*, and *Agamidae*.

Section Rhiptoglossa. Family *Chamaeleonidae*.

Division Antarchoglossa. Section Scincomorpha. Families: *Xantusiidae*, *Scincidae*, *Ancylotropidae*, *Ftyliniidae*, *Dibamidae*, *Gerrhosauridae*, *Lacertidae*, *Tejidae*, *Amphisbaenidae*. Section Anguimorpha. Families: *Eupoecidae*, *Varamidae*, *Dolichosauridae*, *Aigialosauridae*, *Mosasauroidea*, *Pygopodidae*, *Glyptosauroidae*, *Helodermatidae*, *Anguinae*, *Xenosauroidae*, *Anniellidae*, *Zonuridae*.

Sub-order Ophidia (Snakes). Squamata in which the temporal arcade has completely vanished, and the quadrate is very freely movable. The pterygoids have lost all connection with the basisphenoid, and the palate has become mobile, connected to the cranium only by ligaments and by its connection with the maxillae and quadrate. Much of the palate and the maxillae may vanish in burrowing forms. The brain case is completely ossified, the epipterygoid being absorbed into it. The two halves of the lower jaw are loosely connected by an extensible ligament.

The vertebral column is extraordinarily long, in one case containing 565 vertebrae. Each vertebra has a procoelous centrum and a heavy neural arch, on which additional articulating faces, the zygosphenes, and zygantra, are developed. The single-headed ribs are long and are very freely movable antero-posteriorly; by such movements they cause the transversely widened ventral scales to catch the ground, and force the animal along. There is never any trace of a fore limb or its girdle. All three elements of the pelvic girdle may be present in one family, the Glauconidae, but in most this limb is entirely absent. Upper Cretaceous to Recent.

Families: *Typhlopidae*, *Glauconidae*, *Ityidae*, *Uroplatidae*, *Boidae* (boa constrictors), *Xenopeltidae*, *Coleubridae*. As the last family contains nine-tenths of all known snakes it is subdivided into the series *Agiophya* (harmless snakes), *Opisthophya* (poisonous but little dangerous to man) and *Proterophya* (typical poisonous snakes).

Sub-order Pleurosauria. A small group of extinct reptiles including only one or two genera, which may be related to the Squamata; if so, these are not, as usually held, derived from the Archosauria. Aquatic reptiles with a very long body and lizard-like limbs partially adapted for swimming. Limb girdles of Lacertilian type. Skull elongated and depressed, quadrate short and immovable. There is a single temporal fossa, bounded below by a broad arcade composed of the squamosal, postorbital and jugal. There is no supratemporal, and the outer surface of the quadrate is covered by a quadrato-jugal. Upper Jurassic. One family.

Order Sauropterygia (Plesiosauria). Reptiles which show a progressive adaptation to a marine life.

Skull with a single temporal vacancy surrounded by the parietal, squamosal, postorbital and post-frontal, and therefore apparently homologous with the upper temporal vacancy of Rhynchocephalia, and not with the single fossa of Theromorpha and Squamata. The single temporal arcade is formed almost entirely by the squamosal and postorbital, the jugal being a small bone wedged in between the postorbital and the hinder end of the maxilla. A quadrato-jugal is absent. The fenestra ovalis lies high in the side wall of the brain case. The palate is primitive, the posterior nares being anterior, and the pterygoids reaching the prevomers.

Except in Placodonts, the neck is long, often exceedingly so (76 vertebrae in *Elasmosaurus*), the back is long and the tail short; there are usually three sacral vertebrae, but may be more. The cervical ribs, though double-headed in early forms, articulate only with the centra, the single-headed dorsal ribs being supported entirely by the long transverse process of the neural arch.

The pentadactyl limbs are large, and are more or less completely converted into paddles by a flattening and shortening of the radius and ulna and tibia and fibula, and an increase in the number of phalanges. The shoulder girdle consists of scapulae and coracoids, which meet one another in median suture. Clavicles are probably always present, an interclavicle usually so. The ilium is small, the pubis and ischium, though separated by an obturator foramen, are expanded into flat sheets of bone. A strong plastron of abdominal ribs is always present.

Sub-order 1. Trachelosauria. A single, small reptile, with a long neck consisting of 20 vertebrae whose centra support two-headed ribs. Dorsal ribs single-headed and articulating with the long transverse processes of the dorsal neural arches.

Ilium and femur like those of a land reptile.

Lower Trias.

Sub-order 2. Nothosauria. Sauropterygia in which the limbs are still incompletely converted into paddles, the elbow and knee joints still being flexible. Phalangian formula 2, 3, 4, 5, 3 or 4.

In the skull the opisthotic is enlarged distally, and articulates with the squamosal quadrate and pterygoid, so as to close the middle ear cavity behind. Clavicular arch powerful; coracoids

A. From the right side, with lower jaw, B. from above, C. from below, D. osseous

meeting in a short symphysis, which lies behind a line joining the glenoid cavities. Ilium articulating with both pubis and ischium.

Middle Trias, perhaps just appearing in the Lower Trias. Families not discriminated.

Sub-Order 3. Plesiosauria. Sauropterygia in which the limbs are completely converted into paddles, with no freedom of movement at any joint; the number of phalanges in the five fingers and toes is increased, reaching 6, 13, 15, 13, 9 or more. The distal end of the opisthotic is slender, resting on the hinder surface of

the squamosal. Clavicular arch, when present, reduced to flat sheets of bone, supported by the greatly enlarged acromia of the scapulae. Coracoids with a symphysis which extends forward between the glenoid cavities. Ilium articulating only with the ischium. Rhacetic to Upper Cretaceous. Families not yet discriminated.

Sub-order 4. Placodontia. Saurapterygia in which the skull has become modified to support great crushing teeth in the maxil-

FROM "PROCEEDINGS" BY COURTESY OF THE ZOOLOGICAL SOCIETY OF LONDON AND DR. FRASER
FIG. 10.—SKULL AND LOWER JAW OF THE DICYNODONT REPTILE KANEMEYERIA, RIGHT SIDE

lae and palatines. Neck with eight vertebrae, the cervical ribs articulating with both centrum and neural arch; dorsal vertebrae with concave articulations, ribs attached solely to the neural arch. Limb girdles essentially like those of *Nothosauria*, fore limb somewhat paddle-like, but with the primitive number of phalanges. Femur like that of a land animal. A well-developed armour of dermal ossifications both dorsally and ventrally. Middle Trias to Rhacetic.

Order Ichthyosaurus. Reptiles which are fully adapted for a marine life. The head is elongated, the neck short and the tail very long and powerful, provided with a terminal fin, which is the most important swimming organ.

The limbs are paddles, they are never large, and the hind limbs may become very small. The skull has a single temporal fossa which is surrounded by the parietal, supratemporal (often called squamosal) postfrontal, and sometimes frontal. This opening thus appears to differ in its boundaries from all found in other reptiles. The deep, but usually very short temporal arcade is very largely formed by a bone, often called the supratemporal, which is, perhaps, the true squamosal; it contains also processes of the postfrontal and supratemporal, and a quadrato-jugal. The postorbital and jugal are narrow bones round the enormous orbit.

The nostril lies immediately in front of the orbit, and the long rostrum is built up from the premaxillae and nasals. The bilocated vertebral centra are extremely short, and the neural arches feeble. The ribs are two-headed at least anteriorly, and articulate solely with the centra. There is no sacrum. The hinder part of the tail is downturned very slightly in Triassic forms, nearly at right angles in those from the Upper Jurassic, in order that it may support the lower lobe of a vertical caudal fin whose upper lobe has an unossified skeleton.

The shoulder girdle consists of scapulae and coracoids which meet in a powerful median symphysis between the glenoid cavities, and a rigid clavicular arch. The pelvis has a narrow ilium and pubis and ischia, separated by an obturator foramen, but expanded into great sheets in Triassic forms. In both fore and hind limbs the proximal bone is very short and widened distally, the remainder of the limb, in the later forms, being reduced to an interlocking mass of polygonal bones. The number of fingers is often increased to seven or more, and the phalanges increase to a very great number.

Middle Trias to Upper Cretaceous. Families: *Mixosauridae*, *Ichthyosauridae*.

Order Chelonina. Reptiles in which the trunk is enclosed in a shell built up from a series of dermal bones, with which the

neural arches and ribs become continuous. The limb girdles are unique, in that they lie entirely within the ribs. Skull without any temporal vacuity, but the continuous sheet of bone which, in the primitive forms, overlies the temporal muscles may be emarginated either from the back or from below, or from both, so that in extreme cases the squamosal may be left without connection with any other bones of the skull roof. The powerful vertically-placed quadrate is then only supported by its abutment in the pro-otic opisthotic and pterygoid.

Postfrontals and lacrimals are always, nasals usually absent, and the external nares are confluent. Except in *Triassochelys*, the jaws are toothless, and they always support a horny beak. There is often a small secondary palate, not homologous with that of mammals or crocodiles, formed by extensions of the palatines and prevomers. The eight cervical vertebrae are so formed that the neck is flexible, bending into a vertical loop in *Cryptodeira*, and into a horizontal S in *Pleurodeira*.

The dorsal vertebrae are ten in number, the first being free, or nearly so, from the shell, whilst the rest are fixed immovably by their attachment to the neural plates of the carapace; the two sacral vertebrae are similarly attached. The posterior dorsal vertebrae are peculiar, in that each of their neural arches rests on two centra.

The shoulder girdle consists of a scapula, whose acromion process is produced into a long rod lying horizontally, and approaching its fellow in all forms except *Triassochelys*, and a coracoid which form a curious pedunculate glenoid cavity. Cleithra are present only in *Triassochelys*. Clavicles and an interclavicle are entirely detached from the shoulder girdle and form part of the plastron.

The ilium usually articulates, not with the sacral ribs, but with the carapace; the pubis and ischium are lacertilian-like. The limbs are much modified, in order to reach the girdles which lie within the shell, and to allow of their withdrawal in the more primitive forms. The fifth metatarsal is hook shaped. Both feet are pentadactyl, the phalangeal formula never exceeding 2, 3, 3, 3, and being sometimes reduced to 2, 2, 2, 2, 2, 2.

The shell, in its fullest development, consists of a dorsal carapace, built up from a median row of nuchal, preneural, eight neural and two suprapygal bones, and lateral rows, each of eight costals, articulating with the neurals, a variable development of supra marginals may occur secondarily; in their absence the costals articulate with a continuous chain of marginals which connect carapace and plastron.

The plastron consists of three plates anteriorly, the epiplastrae which are clavicles, and an entoplastron, the interclavicle; a pair of hyoplastra, two pairs of mesoplastra, one pair of hypoplastra and one of xiphioplastra. The neural bones are co-ossified with the neural spines of the dorsal vertebrae, the costals with the ribs of the second to ninth dorsals.

Sub-order Amphicheilydia. Chelonina with no power of completely withdrawing the head within the shell, mesoplastra present, pelvic girdle not fused with the plastron. Families not yet discriminated. Middle Trias to Eocene.

Sub-order Pleurodeira. Chelonina which withdraw the head sideways. Mesoplastra usually present, pelvic girdle fused with the carapace, and usually with the plastron. Families: *Pelomedusidae*, *Chelydidae*, *Miotemnodontidae*, *Plesiochelydidae*. Jurassic to Recent.

Sub-order Cryptodeira. Chelonina which withdraw the head vertically. Mesoplastra absent, pelvic girdle never fused with the plastron. Families: *Thalassemydidae*, *Chelydridae*, *Testudinidae*, *Cinosternidae*, *Platysternidae*, *Cheloniidae*, *Protostegidae*, *Dermochelyidae*, *Dermatemydidae*, *Trionychiidae*. Jurassic to Recent.

There is a considerable number of small Palaeozoic reptiles which do not fall into any of the 19 orders defined above. Of these the more important are: *Eosaurus* from the Coal Measures of the United States, which may be *Cotylosaurian*; *Eumotosaurus* from the Upper Permian of South Africa, which may be an ancestor of the Chelonina; *Broomia* from the Upper Permian of South Africa, which may be an ancestral lizard; and *Araucos-*

celis, from the Lower Permian of Texas, which has also been regarded as a lizard ancestor.

Limbs and Locomotion.—The Lower Permian reptiles of all groups possess limbs which either belong to a definite characteristic type or are clearly simple derivatives of it.

In all of them a distinct neck is absent, the body is of circular section, although variable in length, and the tail is usually of considerable size.

The fore limbs were attached to the body immediately behind the head, the upper arm lies parallel to the ground, and was capable of being moved backward and forward only. The elbows were thus pointed directly outward. The forearm lay nearly parallel to the principal plane of the animal, and made a very small angle with the ground. The wrist was large in comparison with the forearm, and the hand possessed five somewhat spreading digits. The hind leg was attached to the body at a considerably higher level than the fore leg. The thigh projected freely from the body, almost at right angles, and the lower leg made a wide angle with it, indeed the stiff knee could not, in many cases, be bent to a right angle. The ankle joint was flexible, and the five toes greatly resemble the fingers of the same animal.

As the large head makes the load carried by the fore legs rather larger than that on the hind, the hand is generally larger than the foot.

These animals, like the lizards and salamanders of to-day, threw their backbones into lateral waves as they walked. Their procedure was as follows:—When the animal is standing with its right fore leg advanced to the greatest possible extent, and the right hand on the ground, the head is turned to the left, and the left hand lies near to it but is ready to be lifted. The trunk is thrown over to the right side and the base of the tail to the left. This body flexure implies that the right hind leg is turned somewhat backward and the left hind leg is directed forward. The left hand is then lifted from the ground by movement at the elbow, and carried forward not only by a movement of the upper arm on the shoulder girdle and a straightening of the elbow, but also by a bending of the backbone so that the head becomes directed to the right. This movement of the back involves a corresponding twist of the pelvis, which brings the left hind leg to its backward position, and makes it necessary to lift the right foot from the ground. The right hind leg is then swung forward by motion, mainly at the hip joint, and the foot placed down as far ahead as possible. During these movements the animal, as a whole, has travelled forward and the right hand is ready to be raised. Its movements agree exactly with those of the left, and it is followed in turn by the left hind foot.

Thus the animal progresses with a waddling gait, the head and body being constantly thrown from side to side of the line along which the animal is moving. The feet are moved one at a time, so that the animal is never standing on less than three of them, and are placed wide apart. This mode of walking must have been extremely slow and clumsy; measurements suggest that a reptile about a yard in length, without the tail, must have made a track 15 in. in width, with a stride of some 6 or 8 inches.

Fossil materials enable us to trace the steps whereby the later reptiles gradually improved their modes of walking, until on one line, they became like the more primitive mammals, walking with their bodies raised high above the ground, the feet brought in towards the middle line and the stride long, whilst along a second course they became bipedal, striding along on their hind legs, with their heads raised high in the air.

The nature of the skeleton and musculature which is associated with the primitive type of locomotion is as follows:—The shoulder girdle consists of the pair of primary elements, each of which is in the most primitive forms, *Seymouria* and *Varanopus*, ossified as two bones, the dorsal scapula and ventral precoracoid. The glenoid cavity has a characteristic shape in that its articular surface is a rather narrow screw-shaped strip of a cylinder whose axis is nearly vertical. The glenoid cavity is shared nearly equally by the two bones. The two halves of the primary shoulder girdle do not touch one another in the mid line ventrally; but are held in position with respect to one another by the powerful

clavicular arch. This consists of pairs of cleithras and clavicles and an interclavicle. Each cleithrum is firmly attached to the front edge, and sometimes to the upper end of the scapula. The clavicle is firmly attached to the front face of the lower end of the cleithrum and has no contact with the scapula; its lower end is curved inward so as to underlie the thorax, and is usually widened, its lower end underlying the lateral margin of the interclavicle. The interclavicle is usually a thin flat bone, with a widely expanded anterior end, and a narrower shaft projecting posteriorly under the sternum, which is unossified.

The whole girdle was held in position by muscles, the serrati passing from the ribs to the inner surface of the scapula and by others, sternomastoids and cleidomastoids passing from the head to the clavicular arch. Posteriorly, the coracoid is attached to the ventral surface of the abdomen.

The humerus of these reptiles has its extremities very much widened and placed nearly at right angles to one another. The articular surface of the head is screw-shaped, and fits the glenoid cavity so accurately that the bone cannot be rotated, and is restricted to a to-and-fro motion along a definite track. The widened proximal end allows the muscles which pass from the humerus to the ventral part of the animal, the pectoral and coraco-brachials, to have a mechanically favourable insertion. The widened lower end of the humerus similarly secures a

FIG. 11.—SKULL OF THE PRIMITIVE THECODONT, YOUNGBUA

A. Right side, B. from above, C. from below, D. occiput

favourable insertion for the flexor muscles which pass from it to the palmar surface of the hand and forearm, and take the whole weight of the anterior part of the body.

The lower end of the humerus bears a hemispherical boss on its front face, with which the head of the radius articulates, and a cylindrical articulation on its end which fits into the sigmoid notch of the ulna. The distal ends of the radius and ulna are widely separated; they articulate with the four bones: radiale intermedium, ulnare and pisiform, of the proximal row of the carpus. The middle row of the wrist usually consists of only

bones, the centralia, one of which forms part of the inner border, whilst the other separates the intermedium from the distal row. This consists of five bones, of which the fourth, which articulates with the ulnare, is the largest. The metacarpals articulate directly with the corresponding carpals and the number of phalanges is 2, 3, 4, 5, 3 respectively. This ensures that the ends of the fingers lie in a straight line at right angles to the animal, when the hand is placed on the ground.

The pelvis is attached to the vertebral column by the sacral ribs, which vary in number in Lower Permian reptiles from one

articulates only with the astragalus, whilst the fibula impinges on both astragalus and fibulare or calcaneum. The calcaneum is always in direct contact with the fourth and fifth (if present) distal tarsal, whilst the astragalus is separated from the first three distal tarsals by a row of two or more, usually one, centrale, the mammalian navicular. There are primitively five digits, the fourth being the longest. The phalangeal formula is 2, 3, 4, 5, 4.

The great majority of the changes which take place in the structures of these limbs during the evolution of the reptiles can be explained by a consideration of the mechanics of the structures under modified conditions of locomotion.

In the line of the mammal-like reptiles, and also in some of the other forms, the first change which takes place in the shoulder girdle is the addition of a bone, the coracoid, to the two existing in the primary shoulder girdle. These animals then acquire a pectoral girdle which resembles the pelvis in that the facet for articulating the proximal bone of the limb is carried almost equally on three bones. The glenoid cavity at first retains its screw shape, the humerus being restricted in its motion to an excursion along an arc lying nearly parallel to the ground. Gradually, as an integral part of the whole process whereby these animals acquired a more rapid and less clumsy gait, the plane of this glenoid cavity becomes twisted round, so that the humerus moves freely in a dorso-ventral direction and the elbow is no longer directed outward, but is drawn in toward the side of the body, nearly to the stage in which it exists in the more primitive mammals. This change results in the restriction of the glenoid cavity to the scapula and coracoid alone, the precoracoid no longer contributing to it.

Concurrently with this change, the humerus took up a more vertical position, so that the muscles connecting it with the coracoid could become smaller, in part because the forces they had to exert were actually reduced and, in part, because their insertion became more favourable. Thus the coracoid and precoracoid suffer steady reduction compared with the scapula. Finally, in order to secure a larger surface for its attachment, one muscle, which serves to support the animal's weight and to drive the humerus downwards, migrates on to the inner surface of the scapula, the tendon by which it is attached to the humerus passing over a notch in the front border of the scapula below the point at which the clavicle is attached to that bone. In this way a definite acromion becomes established, and the upper part of the anterior border of the scapula becomes recognizable as the homologue of the spine of a mammalian scapula.

The most important change in the clavicular arch is the gradual reduction and final complete disappearance of the cleithrum. The other bones sink in from their original position in the skin, so that they become surrounded by muscles on all sides, but otherwise they suffer comparatively little change during the evolution of the mammals.

The great changes in the position of the fore limb during the development of the mammal-like reptiles necessitate corresponding modifications of the structure of the humerus and other limb bones. Of these, the most striking is the gradual narrowing of the two ends of the humerus and their rotation until they become nearly parallel.

In the hand, the number of phalanges in the third and fourth fingers is reduced to three, so that the formula becomes that characteristic of mammals, 2, 3, 3, 3, 3. It is evident that this change is associated with a new pose in which the third finger, which becomes the longest, lies parallel to the mid line of the animal and the others are symmetrically placed on each side of it.

In the pelvis, the most important changes are a widening of the upper part of the ilium associated with an increase in the number of vertebrae in the sacrum, and the development of an obturator foramen, a gap lying in the suture between the pubis and ischium.

The femur so changes its shape that it can lie with the knee directed as much forward as outward, and the lower leg become capable of much freer movement. At the same time the astragalus and calcaneum shorten so that the tibia and fibula rest partly on their upper surface, thus forming an ankle joint which is on

FIG. 12.—SKULL OF THE DINOSAUR, PLATIOSAURUS (GUSTAV FISCHER)

A. Right side with lower jaw, B. from above, C. from below, D. occiput

to four. It consists of three pairs of bones, the ilia, pubes and ischia. These meet in a triadate suture, so that each supports about one-third of the acetabulum, with which the head of the femur articulates. The pubis and ischium of the same side are firmly united by a continuous suture and the two halves of the pelvis articulate continuously, so that the whole structure is usually described as plate-like. The femur is a straight bone, with the articular face of its head placed on the end of the shaft. The condyles at the distal end are only slightly curved, well separated and placed at such an angle as to suggest that the knee could neither be extended into a straight line nor flexed beyond a right angle.

The tibia is a bone with an expanded upper end, and is always shorter than the fibula, which is unusually massed. At their lower ends the two bones are widely separated. The tarsus, in one case (*Seymouria*) has a proximal row of three bones, the tibiale intermedium and fibulare, corresponding with those of the carpus, but in nearly all other reptiles and their descendants, the mammals and birds, the intermedium is no longer found as an independent bone, even during development, and has fused with the tibiale to form an astragalus. As a result of this fusion the tibia

the way to a mammalian structure and the phalangeal formula of the foot becomes reduced to 2, 3, 3, 3, 3.

The non-mammal-like reptiles exhibit so many different types of adaptation that a full analysis of the structures of their limbs is impossible; indeed, it has not yet been systematically attempted. Some of the main types of life are here discussed with reference to a particular case.

Nondescript.—The majority of lizards and Rhynchocephalia exhibit a simple modification of the mode of locomotion found in the most primitive reptiles. In them the body and tail are thrown into lateral waves, which pass steadily backward so that each point along the back swings from side to side across the animal's track as the creature moves forward. The hands and feet are widely separated, the body only just raised off the ground, and only one foot is moved at a time. In detail there is much variety; both fore and hind feet may be much everted, so that the first digits point forward and the toes increase in length from one to four, so that when in the natural position their claws end on a straight line at right angles to the body. In some cases, however, the fingers are directed forward and the hand is nearly symmetrical about the third finger, and even the foot is less asymmetrical than in the more primitive forms. Nevertheless, these animals always retain the original phalangeal formula.

These animals have a primary shoulder girdle consisting of a scapula and precoracoid, the glenoid cavity has lost all trace of the screw shape of primitive reptiles and permits considerable freedom of motion. In the larger and more advanced lizards the anterior part of the scapula and coracoid is much enlarged, and these bones are perforated by fenestrae.

The clavicles have an expanded, and sometimes fenestrated, lower end, and the interclavicle is usually cross-shaped. There is a large sternum, which is usually calcified although not ossified, with whose antero-lateral borders the precoracoids articulate.

The pelvis of these reptiles is of very characteristic pattern, the ilia are narrow rods with an expanded lower end which contributes to the acetabulum. It slopes downward and forward and is firmly held by its articulation with the two sacral ribs. The pubis and ischium are separated by a large obturator foramen which, in many cases in the bony skeleton, is confluent with that of the opposite side. The hind limb presents few features of interest, but it may be noted that a patella is sometimes present, and that most of the motion at the ankle-joint takes place between the two rows of tarsals and not, as in mammal-like reptiles, between the tarsus and lower leg.

One universal and unexplained feature of the hind foot of these reptiles is that the fifth distal tarsal is absent, and that the upper end of the fifth metatarsal has moved up into contact with the calcaneus, and has become much widened so that the whole bone is hook-shaped. As a result, the fifth toe tends to be widely separated from the other four.

This feature occurs in Rhynchocephalia, Thecodontia, Crocodilia, Dinosauria, Squamata, and Chelonina, and has been held to imply a close relationship between these orders.

Cursorial Progression.—The only group of non-mammal-like reptiles which became highly adapted for rapid progress on hard land was the Dinosauria. They arose from Thecodonts whose general body proportions and gait generally resembled those of certain lizards. These animals possessed slender scapulae and small precoracoids, clavicles and interclavicle were present, and there was, in some cases, a sternum with a single pair of ossifications. The fore limb was slender, the hand small and with five fingers. The pelvis had an ilium which was antero-posteriorly extended, but so low that the acetabulum lay on the level of the vertebrae. The pubis and ischium were plate-like, but much elongated and directed largely downward. The hind legs were much longer and more massive than the fore, a condition made possible to a quadrupedal animal by the presence of a long tail, which acted as a counterpoise to the body. Although it is certain that these animals had a straddling gait, it is probable that the feet were placed unusually near to the middle line and the feet were not so asymmetrical as those of most lizards.

From such reptiles the Saurischia, the carnivorous dinosaurs

arose by an increase in the length of the hind legs, and concurrent reduction of the arms. They became predominantly bipedal, a habit which necessitates the raising of the body so far above the ground that the whole animal balances about the pelvis. This pose can only be attained if the thighs are turned in until they lie parallel to the body of the animal, and the feet are placed on the line which marks the middle of the track. Such an arrangement ensures that the body need no longer be thrown from side to side, as it is in all more primitive reptiles.

A further result is that, as the powerful muscles which are used for propelling the animal forward no longer press the heads of the femora into the acetabula, this depression no longer needs a floor and becomes perforated. At the same time, in order to lengthen the muscles attached to them and thus enable the leg to swing through a larger arc, the pubis and ischium, both elongated, stretch downwards and away from one another, meeting only at the acetabulum. The reduction in size of the fore-limb, which occurs because it is no longer required to carry the weight of the body, results in a reduction and final loss of the clavicular arc, and in a reduction in size of the precoracoid. Subsequently, certain carnivorous dinosaurs increased greatly in size and became quadrupedal again, retaining in many parts of their skeleton features which arose during the bipedal stage in their ancestry.

The long limbs which are necessary for a bipedal cursorial life, involve elongated feet. These are secured by lifting the heel entirely off the ground, so that the animal walks on the ends of the metatarsals, the toes stretching out along the ground as they do in birds. As the foot is placed directly under the body it tends to become symmetrical about the middle third toe, and rapidly becomes either functionally or actually tridactyl. The hand, which serves as a grappling hook for catching the prey, is reduced to three fingers, all provided with claws, that on the thumb becoming very large indeed in the latest forms.

The other group of dinosaurs, the Ornithischia, pursue a somewhat similar course of modifications; they also become bipedal, some of them secondarily returning to a quadrupedal life. But in them the extension of the pubis and ischium into long downwardly directed rods, which is necessary to afford suitable muscle attachments, takes place in such a way that the pubis acquires two branches, one directed downward and forward, the other directed backward so that it lies parallel to the ischium. The early stages of this arrangement are not known, but it persists throughout the whole group.

Flight.—One group of lizards, the genus *Draco*, has the habit of living in trees and of passing from tree to tree by making great

BY COURTESY OF THE GEOLOGICAL SURVEY, DEPARTMENT OF MINES, CANADA

FIG. 13.—SKULL AND LOWER JAW OF THE ORNITHOMID DINOSAUR KRITOSAURIUS

leaps, whose length is extended by the presence of a parachute, made by flaps of skin which project from the sides of the body and are supported by the much elongated ribs. Such gliding is scarcely flight in any true sense, it cannot be maintained by any action of the animal whilst in the air, and its extent is limited by the speed acquired at the original jump and by the height of the point of departure. A similar gliding habit, carried out without any elaborate mechanism by a mere concavity of the ventral surface, is exhibited by certain arboreal snakes from Borneo. The only reptiles which have acquired true flight were

the extinct Pterodactyls.

There are two series of the animals, in one of which the tail is extremely short and probably functionless, whilst in the other the tail is a very long stiff rod bearing a horizontal fin at its hinder end. The presence of this fin renders the maintenance of the body on an even keel much easier than it can have been in the tailless forms. The wing of every pterodactyl consists of a fold

FIG. 14.—SKULL OF A CROCODILIAN, THE ALLIGATOR: (A) LEFT SIDE, WITH LOWER JAW. (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT (AFTER ANDREWS)

of skin which is supported by the greatly extended fourth finger and by the hind leg; it may or may not have connected the hind legs together, either directly or by passing on to the base of the tail. The structure of the fore limbs, which enabled these animals to perform automatically the many carefully-adjusted movements which are necessary for flight, is so strictly determined by mechanical considerations that it is practically uniform in all known species of the group.

In all of them, the scapula is an elongated narrow rod of bone which may articulate with the neural spine of the dorsal vertebrae. Its lower end forms the upper half of the glenoid cavity and is fused with the coracoid. This bone is elongated and straight, its distal end rests in a groove in the front of the large sternum, so that it is enabled to take directly the stresses resulting from the powerful wing muscles. The humerus is short, and the radius and ulna lie parallel to one another. The carpus consists of three bones, with the distal of which the wing metacarpal is articulated, so that it can revolve on its axis. The main joint at which the wing was folded lay between the metacarpal and first phalanx. The movements at the elbow and wrist are inseparably connected, and serve to alter the camber and angle of attack of the wing, thus enabling the animal to fly at varying speeds. It is interesting to note that a successful aeroplane, with an unusual range of flying speed, has been designed on lines suggested by the tailless pterodactyls.

Swimming.—Two extreme modes of swimming are open to a tetrapod. It may convert its limbs into paddles by whose actions it rows itself through the water, or it may use its tail as a propeller, either flattening it and causing waves to pass along its length or producing a fin at the extreme tip, which can be used like a screw propeller. Both types are found in reptiles.

The Chelonians include amongst the fresh water tortoises a number of animals which swim well with limbs which, except for the webbing of the toes, are much like those of a land animal. But in the marine turtles and in the fresh water *Carettochelys* from New Guinea, the limbs are transformed into paddles, mere bags

of skin surrounding the whole of the elongated digits.

The Plesiosaurs carried this principle to its limit; in them each limb is a rigid oar, flattened and widened distally, circular in section where attached to the body. It was feathered when brought forward, then turned so that its broad plane was vertical for the swimming stroke.

The crocodiles, the semi-marine lizard *Amblyrhynchus*, and the sea snakes are the living exponents of the second mode of swimming. In them the powerful tail is laterally flattened, and is swung from side to side so that a series of waves passes along its length. The limbs are used for steering and for maintaining stability in the water. The only groups of reptiles which have formed a caudal fin are the Ichthyosaurs and the marine crocodiles of the family *Metriorhynchidae*. In each case the end of the vertebral column is suddenly turned down so that it passes into the lower lobe of a forked fin whose upper lobe is supported only by non-ossified structures. These animals show a reduction of the limbs, the pelvic limb of Ichthyosaurs and the pectoral limb of the crocodiles being reduced to a tiny paddle.

Limbleness.—Many lizards belonging to unrelated families, but chiefly of burrowing or sand living habits, exhibit a reduction of limbs associated with an elongation of the body. The process takes place gradually, all stages being known in one or other form between normally developed limbs and their complete absence. In snakes the reduction is always complete in the case of the fore limbs, whilst the hind limbs may be represented by a claw-like spur on each side of the vent. In some cases all three bones of the pelvis and the femur may be present. Normally, all trace of limbs, except for a rudimentary nerve plexus, is lost.

Skin.—The fact that the reptiles were originally distinguished from the amphibians by their more completely terrestrial habits, implies that in them the skin had become capable of withstanding desiccation, and the serious wear to which it became exposed.

The skin of amphibians is maintained in good condition by a coat of mucus, poured out from glands which lie all over it; that of reptiles is dry and covered by a watertight layer of horn, very well adapted for resisting abrasion. The horny layer, though continuous, is not of the same thickness throughout, but is divided into specially thickened areas, the scales which are connected by flexible regions. The scales may be flat, fitting together like a mosaic or separated widely, or they may be prolonged backwards so that they overlap and are overlapped by others, like slates on a roof. The scales often have a definite arrangement, which is used in the classification of Squamata.

The skin, as in other Amniotes, consists of a compound squamous epithelium which rests on a corium built of connective tissues. The actual scale consists of the keratinized outer layers of the epidermis, its thickness is increased by additions to its inner surface, and it grows in area either all round or at one end. The area of the scale is always raised by a special papilla of the corium, which may project so far that the scale overlaps that behind it. The scale is colourless, its transparency allowing the pigment in the cutis to show through.

The outer layer of the keratinized epithelium is worn away in crocodiles and Chelonians, but in the Rhynchocephalia and Squamata it comes away either in flakes or, in some lizards and snakes, in one piece. Such cast skins exhibit perfectly the continuity of the horny skin, which in them even covers the eyes. This process of shedding the skin is facilitated in some or all of these reptiles by a special mechanism which allows the head to be distended with blood. The papilla of the corium which fills the centre of each scale may, in crocodiles, some lizards and many fossil reptiles, be ossified as a bony scute.

The carapace and plastron of the Chelonians consist essentially of such scutes. Each ossifies in the corium, the bone finally occupying nearly the whole thickness of that layer, leaving only a thin sheet of connective tissue to support the peritoneum, and a similar sheet containing pigment cells below the epidermis in which the horny shields are developed. The originally dermal ossifications of the carapace extend so far down into the body of the animal that, in the end, they completely surround the middle parts of the ribs, which first calcify and are then ossified by ex-

tension of membrane bone from the scute.

Most of the glands found in the skin of reptiles are scent glands, which give to these animals their characteristic odour of musk, which has, no doubt, a sexual significance. All these glands are sac-shaped, multicellular structures opening by a pore on the surface, and their secretion is set free by disruption of cells.

The musk glands have the following distribution:—In crocodiles there is a pair which open by longitudinal slits on the inner sides of the lower jaws, and another pair lie within the lips of the cloaca; these are present in both sexes. Crocodiles possess also a row of small sac-like glands without external openings along each side of the back.

In Chelonia there is a pair of inguinal glands opening near the hypoplastra, and sometimes an anterior pair similarly related to the hyoplastra. Sphenodon has a pair of cloacal glands. Lizards have cloacal glands and, in addition, in certain forms there are the so-called femoral pores, which extend along the lower and hinder surface of the thigh to pass on to the belly in front of the cloaca. They are present in both sexes, but best developed in males. Each pore opens in the middle of a scale and leads into a canal which ends in a pocket with many shallow diverticula. The cells of the walls of these become detached, filling up the lumen of the gland and duct, and forming a rod which may project beyond the surface of the skin. It is possible that these structures are of assistance in copulation.

Muscular System.—No useful account of the muscles of reptiles can be given here, the functional effects of those used in locomotion are described in the section *Locomotion*.

Body Cavity.—The body cavity of reptiles is always more or less completely divided into sacs. A completely closed pericardium is always present. In lizards, a post-hepatic septum built up by special folds of the mesentery and suspensory ligament of the liver, may reach the ventral surface and bring about an almost complete division of the peritoneal cavity into two. In snakes, similar folds enclose the two lobes of the liver and the stomach in separate sacs. In Chelonia, the lungs lie above a fold of peritoneum which reaches the liver, excluding them from the general cavity. In crocodiles, there are two pleural cavities and a combination of other folds connected with the liver forms a complete transverse partition separating the pericardium, lungs and liver from the rest of the peritoneal cavity. This sheet is muscular, and probably functions in respiration like the non-homologous mammalian diaphragm.

Digestive System: Teeth.—The teeth of reptiles may be found on the pre-maxillae, maxillae, on all the bones of the palate, and on the dentary and coronoid bones of the lower jaw. Individual teeth are generally simple cones with a conical pulp which produces dentine and an enamel cap. They may be set in sockets (theodont) or fused to their supporting bone (acrodont or pleurodont). In the majority of reptiles they are shed periodically, and replaced as often as necessary. In reptiles, the marginal teeth of both jaws appear to belong to two series, whose members alternate with one another, and in primitive forms were functional alternately.

Thus, in these animals two teeth are usually separated by an empty emplacement in which a new tooth will arise, the original pair being shed together when it has grown to its full size. When the original teeth have been shed a new dental papilla passes outward from the lingual side to the empty socket and there produces a new tooth. In crocodiles this process has already happened before the tooth is shed, so that these new tooth crowns may often be found in the pulp cavity of the original tooth. Sphenodon, and some other recent reptiles with acrodont teeth, exhibit no replacement after maturity has been reached. The mammal-like reptiles in their various orders show all stages in the reduction of teeth change from the primitive unlimited replacement of all teeth to a mammalian condition in Cynodonts, where the incisors, canines and pre-molars are replaced once during the animal's life, and the molars, when once formed, are never shed.

The dentition of reptiles is usually homodont, that is, uniform or regularly varying from front to back of the jaw, but the

Theriodont dentition is heterodont and mammal-like. The tooth crown may be elaborated into a crushing mechanism, in Placodonts, some Ichthyosaurs, and very effectively in the Trachodont dinosaurs, where several successive series of teeth are in use at one time, forming a splendid triturating surface, in Cetylosaurs, Theromorphs, and even, though imperfectly, in some lizards. The peculiarly specialized fangs of poisonous snakes are described in the article on these animals.

Tongue.—A tongue is present in all reptiles. In crocodiles and Chelonia, it is a short, broad, fleshy structure attached to the floor of the mouth over a large area. In crocodiles, a fold on the hinder margin of the tongue engages with a similar structure of the palate, so as completely to separate the air passage from that for food. In lizards the tongue may be flat, broad and not protrusible; it may be narrow, cylindrical and capable of being extended out of the mouth, or its cylindrical anterior half may telescope into the posterior portion, so that the whole can be projected far in front of the snout. This last type reaches its climax in the chameleon (*g v.*).

Buccal Glands.—The only salivary gland of universal occurrence in reptiles is a sub-lingual. Upper and lower labial glands occur only in lizards and snakes, where they are arranged in rows between the lips and the teeth. The poison glands of the lizard *Heloderma*, and of the snakes, are special developments of such upper labial glands. They are described in the article *SNAKE*.

Gut.—In Chelonia, Sphenodon, lizards and snakes, the oesophagus passes gradually into the stomach, which is, in them, usually spindle-shaped, with its openings widely removed from one another. In crocodiles, the stomach is placed more transversely, the opening of the oesophagus and the pylorus being approximated. This stomach is an oval sac whose proximal portion is very muscular, recalling, in its arrangement, the gizzard of a bird; indeed, it customarily contains pebbles used for triturating food. The pyloric end of the stomach is distinct. The stomach always contains gastric glands.

FIG. 15.—PTERODACTYLUS SPECTABILIS FROM THE LITHOGRAPHIC STONE

A pyloric valve usually exists, and the duodenum is not usually sharply marked off from the rest of the small intestine; only in crocodiles does it form a loop round the pancreas as it does in birds and mammals. The walls of the mid gut are usually thrown into folds or ridges, but seem to contain few or no glands. There is usually or always an ilio-colic valve separating the mid from the hind gut; immediately beyond this the latter gives rise to a caecum in some lizards and snakes. The rectum ends in a cloaca which is usually of elaborate structure.

Cloaca.—The cloacal opening leads into a proctodeum, a cham-

ber whose walls give origin to the copulatory organ or organs in the male, and their representative in the female duct to the pair of anal glands; the peritoneal canals when present open into it.

Copulatory organs are absent in *Sphenodon*, in *Squamata* they are a pair of papillae capable of being protruded through the lateral ends of the transverse cloacal slit, and of being retracted, being turned inside out by the contraction of special muscles

an additional cloacal chamber, the coprodeum, which serves for the storage of faeces.

Urogenital System.—The kidney of an adult reptile is always a metanephros, discharging by a single ureter. The kidney may be elongated and its surface furrowed, or it may be a small compact organ. The urine of *Chelonia* and *Crocodylia* is fluid, that which is voided by snakes and lizards contains crystals of insoluble urates, an arrangement which prevents waste of water in these animals, which often live in very arid surroundings.

The ovaries are always paired, and large owing to the size of the yolk eggs. Interstitial tissue is small in amount. The oviducts have independent funnel-shaped ostia, and are usually provided with glandular walls which secrete the albumen and shell. In some viviparous forms they can combine with the faetal membranes to form a placenta. The elongated testes are connected with an epididymus of mesonephric origin.

Respiratory System.—All reptiles breathe by lungs. These are always produced by the elaboration of a median ventral outgrowth of the pharynx. The glottis lies immediately behind the tongue and is sometimes protected by a rudimentary upstanding epiglottis. There is a larynx, supported by arytenoid and cricoid cartilages, there being no thyroid cartilages; muscles passing from the laryngeal cartilages to the "hyoid" enable the glottis to be opened and closed. There are often vocal chords, which give to *Sphenodon*, crocodiles, some tortoises and lizards a voice, usually a grunt or squeak. The trachea is often long and its cavity is kept open by cartilaginous rings. The bronchi may be very short in *Sphenodon* or very long in tortoises. The lung is very variable in its structure; it may be almost as primitive as in *Amphibia* or become comparable to that of a bird.

In *Sphenodon* and snakes the cavity of the lung is single, but the walls are divided up into a series of cells by upstanding ridges or septa. In some lizards certain of these septa elongate so that the original single sac begins to be cut up into lobes, each with cellular walls. In crocodiles, this process has gone on so far that the lung is definitely divided into a number of chambers each of which receives a number of wide side canals, the parabronchi, in whose walls lie the alveoli. In *Chelonia* this process has gone so much further that the whole lung is spongy, the alveoli, through whose walls the whole of the respiratory exchange takes place, being connected with an irregularly branched series of bronchial tubes.

Not only is the actual structure of the lung altered in this way, but reptiles show an advance over the *Amphibia* in an increased size of the lung resulting from the development of a special anterior projection, the prebronchial part, which, very small in *Sphenodon*, becomes much more extensive in more advanced reptiles. In chameleons, long, hollow non-respiratory process of the lungs pass backward among the viscera; they are important as morphological forerunners of the air sacs of birds and *Pterodactyls*. In elongated legless reptiles one of the lungs is usually reduced, and may be absent.

The mode of respiration in *Reptilia* is not well known. In all except the *Chelonia*, movements of the ribs may be expected to draw air into the lungs, whilst the muscular post-hepatic diaphragm of crocodiles is, no doubt, used as is the comparable structure in mammals. In *Chelonia*, and probably also in other reptiles, air is actively forced down into the lungs by movements of the floor of the buccal cavity brought about by the hyoid and its musculature. In *Chelonia*, the protrusion and withdrawal from the shell of the neck and legs gives a pumping action which, by creating a virtual vacuum, draws air into the lungs.

Vascular System.—The heart of reptiles lies in the thoracic region, usually between the lungs. There is a sinus venosus, at least in most, which opens by a valve guarded slit into the right auricle. Right and left auricles are completely separated, and open independently into the ventricle or ventricles. The lower edge of the interauricular septum is expanded laterally into, usually, very large right and left membranous valves, which direct the arterial blood to the left, the venous to the right side of the ventricular cavity. The ventricle is incompletely, or, in *Crocodylia*, completely divided by an upstanding ridge into right and left

FROM WILLISTON, "WATER REPTILES OF THE PAST AND PRESENT" (UNIVERSITY OF CHICAGO PRESS)

FIG. 16.—SKULL OF THE RHYNCHOCEPHALIAN, SPHENODON: (A) LEFT SIDE, (B) FROM ABOVE, (C) FROM BELOW, (D) OCCIPUT

derived from the tail musculature. Each has a groove on its lateral surface which extends on the wall of the cloaca nearly to the opening of the vas deferens. In crocodiles and *Chelonia*, a median unpaired penis arises from the ventral wall of the proctodeum; it can be erected through the activities of corpora cavernosa, and is then extruded through the anterior end of the longitudinal cloacal slit. The dorsal or posterior surface of the penis is furrowed by a deep groove, which is probably converted into a canal during erection. The groove leads backward to the openings of the seminal ducts.

The proctodeum is separated by a ridge which is, in effect, a sphincter, from the urodaeum, into which the ureters, vasa deferentia, oviducts and bladder open. A bladder is found in *Sphenodon*, *Chelonia* and most lizards; it is absent in all other reptiles. The urodaeum is partially subdivided in many reptiles; in snakes a dorsal recess receives the ureters and gonoducts; in crocodiles they open into the dorsal side of the urodaeum, whilst in *Chelonia* they discharge directly into the neck of the bladder. In *Sphenodon*, lizards and snakes, the oviducts open rather dorsally, in crocodiles and *Chelonia* ventrally, the vasa deferentia having a similar opening in all forms.

The urodaeum is, in some aquatic *Chelonia*, produced into a pair of their walled sacs on the dorsal side, which are constantly filled and emptied of water, thus serving as accessory respiratory organs. In all reptiles except crocodiles and *Chelonia* there is

halves. Except for a possible relic in *Sphenodon*, there is no trace of a conus arteriosus nor of a truncus. Three arteries arise independently from the ventricle, and are then twisted round one another like a rope, so that they cross one another. That vessel whose origin is most to the right is the left systemic arch, the next is the pulmonary arch, and the third is the right systemic-carotid, from which arise both carotids. As a result of this arrangement, in *Chelonina* the pulmonary arch arises from a partially separated *cavum pulmonale*, and the two systemics from a *cavum venosum*, which has to be traversed during systole by the blood from the left auricle, which is originally discharged into the *cavum arteriosum* on the left side of the ventricle. In crocodiles, the right systemic-carotid alone leaves the left ventricle, whilst both pulmonary arch and left systemic come off from the venous right ventricle: but in them the left and right systemics are connected by a special opening, the foramen of Panizzi at the point where they cross. Although it has been shown by the electrocardiograph that the nature of the contraction of the heart in tortoises is much as in mammals, very little is known of its general physiology.

Arterial System.—The pulmonary arch soon divides into two branches, one to each lung; in *Sphenodon* and some lizards it gives off a paired laryngotracheal artery which is a relic of a

into the left auricle.

The venous blood is returned to the heart by the pair of pre-caval, and single postcaval veins which open into the sinus venosus. The branches of the precavals come from the head and fore limb, the subclavian often receiving an azygos vein from the anterior part of the body wall which represents part of the embryonic posterior cardinal. Nearly the whole of the blood which

FIG. 17.—SKULL OF A TORTOISE, *TESTUDO*

Urodela structure. The systemic arches unite to form the dorsal aorta; from one or both of them arise coronary arteries to the heart. From the right come off both subclavians, and the left usually gives off a coeliac branch. The carotids may arise independently from the right systemic-carotid, or may be formed by the branching of a single primary carotid. In snakes the right carotid is usually much reduced or absent.

Venous System.—The venous system is exceedingly complicated, differing in details in the four orders but with a common ground plan. The pulmonary veins pass straight from the lungs

FIG. 18.—SKULL OF THE LIZARD *CHAMAEDON*
A. Right side, B. from above, C. from below, D. occiput

enters the heart through the postcaval has previously passed through one of the portal systems.

The renal portal system drains the tail, and part of the hind limbs, the afferent renals arising from the bifurcated anterior end of the caudal vein and the iliacs. The efferent renals open into the postcaval, whose hinder end is formed by them. The supra renal portal system consists of a series of afferent veins which come from the body wall; the efferents discharge with the gonadal veins into the postcaval.

The hepatic portal system includes the series of veins from the gut, which form the true hepatic portal vein and also the median anterior abdominal vein, which is originally formed by a fusion in the middle line of pelvic veins, themselves built up from the iliacs and a series of vessels from the hinder part of the body wall of the abdomen. The anterior abdominal passes along in a mesenteric sheet in the ventral part of the body cavity to enter the liver and there receive the hepatic portal or a branch from it. Finally, the whole of the blood in the liver passes by the hepatic veins into the posterior cardinal.

Lymphatic System.—Definite lymphatic canals are well developed in reptiles; those of the head unite into thoracic ducts which open into the innominate veins. There is a pair of posterior lymph hearts discharging into the iliacs.

Blood.—The red blood corpuscles are oval, biconvex and nucleated; they are larger than those of birds and mammals, smaller than those of Amphibia.

"**Ductless Glands.**"—A spleen is constantly present in reptiles, placed near the stomach or within the loop of the duodenum behind the pancreas. The reptilian thyroid is a median structure placed somewhere on the ventral surface of the trachea.

There are two pairs of thymuses in Sphenodon and lizards, derived from the second and third pharyngeal pouches in the latter. In snakes there are usually two pairs derived from the

mammals. The nasal cavity finally opens to the palate by the internal nostril, which may be carried far back by the formation of a secondary palate.

Jacobson's organ is, in Chelonia, a mere diverticulum of the ventral part of the nasal cavity. In Squamata it becomes an independent chamber, separated from the nasal cavity by the septomaxillary bone; it then has a special opening to the palate and may be very highly developed, receiving a large proportion of the olfactory nerve fibres. Its function is clearly to smell food after it has been taken into the mouth.

Jacobson's organ soon vanishes in crocodiles. A special nasal gland is developed in the concha of reptiles, and the naso-lachrymal duct opens on the lateral wall of the nasal cavity.

Eye.—The eyes of reptiles are normally provided with movable upper and lower eyelids, and a nictitating membrane which is usually transparent and can be drawn across the cornea. The nictitating membrane may vanish in some lizards; in snakes it is permanently drawn across the eye, fuses with the remnant of the upper eyelid, and has a cornified scale on its outer surface, which is shed with the rest at ecdysis.

In some desert lizards the lower eyelid has a transparent window in the middle and is fused with the upper. In chameleons there is no nictitating membrane, and the upper and lower eyelids fuse, leaving only a small hole the size of the pupil. There are Harderian, conjunctival and lacrimal glands, whose secretion is discharged into the nose and palate by the naso-lachrymal duct.

The sclerotic coat of the eye ball often contains a ring of supporting ossicles, the cornea is convex. The crystalline lens is supported in a capsule by ciliary muscles, and accommodation can be carried out over a wide range.

The iris is usually brightly coloured, and the pupil can contract either to a circular or a slit-like condition. The pupillary reflex to light is usually difficult to evoke. The retina is built up of

FIG. 19.—(A) SKULL AND LOWER JAW OF PYTHON (NON-POISONOUS). (B) SAME FROM ABOVE. (C) LEFT SIDE OF SKULL AND LOWER JAW OF RATTLESNAKE (POISONOUS)

dorsal extremities of the fourth and fifth pouches. A variable series of epithelial bodies, either dorsal or ventral, is present, and there is an ultimobranchial body of the left side, at any rate, in lizards.

Nervous System: Sense Organs.—Skin. Tactile corpuscles are found in the cutis of all reptiles. In crocodiles a group of them lies at the bottom of a pit, filled with non-confined cells near the anterior border of each of the large ventral scales. In Chelonia they lie in the thin layer of connective tissue between the epidermal scutes and the bony shell. In certain Agamids some of the scales of the dorsal surface bear long rod-like projections and are surrounded by nerve endings so that they may function as specialized tactile organs as do some mammalian hairs.

Taste.—It is clear that some sense of taste exists, the taste buds being probably on the tongue.

Smell.—The sense of smell is well developed in all recent reptiles, although it was much reduced or absent in the later Pterodactyls.

The external nostril, often provided with a valve, leads into a short vestibule, which opens out into the true olfactory chamber, whose wall is lined with the sensory epithelium which contains the olfactory cells. The area of the surface of this epithelium is increased by the presence of a ridge, the concha, which stretches into the cavity from the outer side. In crocodiles there is an additional concha, and there are reasons for believing that in Cynodonts, ethmo- and naso-turbinals were developed as in

FIG. 20.—SKULL OF THE PELIOSAUR, SPHENACODON. (A) RIGHT SIDE, WITH LOWER JAW, (B) FROM ABOVE

small elements, both rods and cones being present in some forms, rods or cones alone in others. The retina, like that of birds, often contains pigmented oil granules, yellow, red, green, and, in Chelonia, blue and violet. Nutrition of the contents of the eye ball is secured, in many reptiles, by the presence of a pecten, a pigmented vascular projection, at first conical and when more highly developed fanshaped which arises from the fundus. A pecten is absent in Sphenodon and rudimentary in Chelonia. In snakes its place is taken functionally by a vascularization of the choroid. In chameleon there is a macula and fossa like that of

birds or primates. The eyes of reptiles are always laterally directed, but can be moved through a small arc of about 20°. They possess the normal series of six eye muscles and a retractor bulbi in addition. Reptiles appear to possess a colour sense, but accurate observations are lacking.

Pineal Eye.—In Sphenodon and lizards the epiphysis of the brain lies in a foramen between the parietal bones, and is covered by a transparent scale. It ends in a vesicle whose outer wall is lens-shaped, whilst the lower surface is a pigmented retina. It appears to exhibit no perception of light. The immense size of the pineal foramen in some fossil reptiles suggests that the pineal eye was functional in them.

Ear.—All reptiles have an inner and middle ear, an outer ear being present in crocodiles and the extinct Cynodonts. The inner ear is more advanced than that of Amphibia in that the utriculus is connected to the swollen sacculus by a duct from which the endolymphatic duct rises. There is a lagena which, in crocodiles, becomes much elongated and provided with a rudimentary organ of Corti seated on a basilar membrane.

The endolymphatic duct ends blindly, usually within the skull, but in Geckos is extended into a sac under the skin of the neck. There is a special perilymphatic duct which forms a closed tube definitely associated with the lagena. In crocodiles this begins to form definite scalae comparable to those of the mammalian cochlea.

The cavity of the middle ear is formed by an upgrowth from the first visceral pouch; in Sphenodon and lizards the cavity communicates with the pharynx by a wide opening, in Chelonia by a narrow Eustachian tube. In crocodiles the Eustachian tubes of the two ears meet and form a duct running in a special canal between the basisphenoid and basioccipital to open in the middle line just behind the choanae; lateral branches from the duct pass in canals between the basisphenoid and the pterygoids up into the supraoccipital and cranial roof, there enlarging into air spaces which again communicate with the tympanic cavities. Finally, a tube rising from each cavity leads air down into the quadrate and lower jaw. The history of this elaborate arrangement can be made out from fossil materials. In snakes, the tympanic cavity is totally obliterated. The outer wall of the tympanic cavity is the tympanic membrane, which, in crocodiles and most lizards, is a thin sheet sunk below the surface of the head at the lower end of an external auditory meatus. In Sphenodon and Chelonia it lies flush with the surface, and its outer surface is indistinguishable from that of the neck. In snakes and chameleons it is absent.

The tympanic membrane is connected with the fenestra ovalis by a rod, whose inner end is an ossified columella or stapes, whilst the unossified outer end is the extra columella. This is small and simple in Chelonia, absent in snakes, where the end of the stapes articulates with the quadrate, and in Amphibiae. In lizards, the extra columella has a dorsal process attached to the end of the paroccipital process, and often detached, a ventral process applied to the quadrate, and a plate for insertion in the tympanic membrane. The whole structure is of hyoidian origin, and the hyoid articulates with the end of the paroccipital process. In Sphenodon it fuses with the end of the extra columella, and in crocodiles it arises from its shaft to pass down the air canal to the lower jaw and become continuous with Meckel's cartilage.

Most or all reptiles are capable of hearing, but we know nothing of their ability to discriminate musical notes.

Peripheral Nervous System.—The spinal nerves of reptiles agree in all important characters with those of other Tetrapods, the only interesting peculiarity being the presence in snakes of rudimentary pectoral and pelvic plexuses, relics of the limbs of their ancestors.

The sympathetic system presents an advance over that of most Amphibia in that many of the ganglia in the thoracic region are fused into a single large ganglion, and that the cervical sympathetic is separated into deep and superficial portions, each running continuously from the ganglion of the vagus to the thorax, the details varying in different orders. This arrangement is derived from that of Urodeles and leads directly to birds.

The cranial nerves of reptiles differ from those of living Amphibia in the absence of all trace of the lateral line system, except the auditory nerve, in the presence of a spinal accessory nerve XI, and in the fact that the hypoglossal nerve XII, passes out through the occipital bone.

Brain.—The reptilian brain is larger proportionately than that of an amphibian of the same size. The cerebral hemispheres

FIG. 21.—SKULL AND LOWER JAW OF THE *ICHTHYOSAURUS OPHTHALMOSAURUS*: (A) LEFT SIDE, (B) FROM ABOVE, (C) FROM BELOW

are pointed and usually pass gradually into the olfactory lobes. Their hinder ends are free and often project posteriorly so as to conceal the diencephalon.

In Sphenodon and in Chelonia the whole of the upper surface of the hemisphere, from the hippocampus on the inner surface to the lateral face, is covered by a pallium, devoted to the sense of smell. This layer of cells then turns inward from the surface, and lies on the top of the corpus striatum, forming a hypopallium. In lizards, and especially in crocodiles, the dorsal surface of the hemisphere becomes less and less nervous until, in birds, it is a mere membrane playing no part in the functioning of the brain. In these reptiles the hypopallium becomes broken up by a penetration of nerve fibres, loses its pallial appearance and becomes assimilated to the corpus striatum. Thus, presumably in these animals, and certainly in birds, behaviour is controlled and memory exercised by a part of the brain quite different from that which fulfils these functions in mammals. In some reptiles, at any rate, the first trace of the neopallium, which is the important and developing part of the brain in mammals, is represented by a small cortical area in which alone other senses than smell gain a direct representation.

The mid brain of reptiles has its roof thickened and raised into a pair of optic lobes, which not only receive the endings of the optic nerves from the retina but are the motor area, stimulation of which brings about movements of the body.

The cerebellum of reptiles is always larger and better developed than that of Amphibia, though in living forms it is not externally divided into regions, as is that of a bird or mammal.

The brain of the extinct pterodactyls is interesting because, in the reduction of the olfactory lobe, the large size of the cerebellum and the lateral position of the optic lobes, it exactly resembles that of a bird, is indeed more like that of recent birds than is the brain of Archaeopteryx, which is the most primitive member of that class.

Reproduction.—Fertilization of the reptilian egg always takes place internally, in contrast to the condition in many Amphibia.

The egg is always large and provided with so large a store of food materials in the form of yolk that the growing embryo, without any additional materials, can hatch in a form capable of fending for itself, and is, indeed, usually a miniature copy of its parents.

This ovum is surrounded by a semi-fluid layer of albumen, and enclosed in a membranous shell which may be calcified as is

FROM THE CATALOGUE OF MARINE REPTILES OF THE OXFORD CLAY, BY COURTESY OF THE BRITISH MUSEUM

FIG. 22.—SKULL OF THE PLESIOSAUR, MURAENOSAURUS
A. From the left side, B. from above, C. from below

that of a bird. Usually the egg is laid before development has gone far, but in some cases it is retained within the oviduct until the foetus is ready to be born. These animals, including many lizards and snakes, are thus viviparous. In their case the egg shell is thin, and food materials may pass through it; indeed, in some cases it is practically absent, and the little lizard secures nourishment from its mother through a special placenta.

Cleavage is meroblastic, resulting only in the formation of a primitive plate of cells. Gastrulation involves an actual invagination, resulting in the formation of an archenteron which has both floor and roof. The process is, indeed, similar in principle to that in the Gymnophionan Amphibia. No primitive streak is formed behind the blastopore in Chelonia, Sphenodon, lizards or snakes.

The later development much resembles that of birds or monotremes. A headfold is formed, followed by tail and lateral folds, which gradually raise the embryo from the yolk and extra-embryonic structures. An amnion arises from the extra-embryonic somatopleure, as in birds, and an allantois is formed later by a ventral outpocketing of the hind gut. It serves not only as a reservoir for the excretory products of the embryo, but also as a respiratory organ. The embryo breaks its way out of the shell by the aid either of an egg-tooth, placed mesially on its nose or of a caruncula on its head.

Further details will be found in the article VERTEBRATE EMBRYOLOGY.

Mode of Life.—No general statements can be made about the habits of reptiles. If the extinct forms be taken into account it will be found that they have occupied all the habitats which are to-day filled with mammals, except that they are excluded from polar regions by the impossibility of hatching their eggs there, and in extreme cases of achieving a sufficiently high rate of metabolism. The temperature of the body of reptiles, like that of Amphibia, and unlike that of the birds and mammals, is determined by that of their surroundings, rising when the animal is in a warm place, and sometimes becoming very high in bright

sunlight, and falling at night, perhaps to freezing point. The animal's muscular activity always keeps it a very few degrees above the air temperature. Some idea of the variety of habit of reptiles may be gathered from the section on *Locomotion* in this article, and further facts from the articles: LIZARD, TURTLE, CROCODYLIAN, and SNAKES.

Geographical Distribution.—Apart from the limitation imposed by temperature, no general statements can be made about reptilian distribution; any useful account would occupy much space, and involve a discussion of the interrelationships of the families of lizards and snakes, a disputed field.

Geological Distribution.—The earliest bone which has been referred to a reptile is an isolated femur from the Lower Carboniferous of Scotland. *Bosaurus*, from the Upper Carboniferous (Middle Coal Measures) of Ohio, is probably a reptile, and *Solenodonsaurus*, from the top of the Upper Carboniferous of Czechoslovakia is certainly one.

The evolution of the reptiles was rapid, nearly all orders being fully established by the end of Triassic times. Several important orders became extinct at the end of the Trias, but the reptiles were the dominant group of vertebrates to the end of the Mesozoic, when, within a short period though not simultaneously, many orders became extinct, leaving only the four which still survive.

Economic Importance.—Reptiles are of slight importance to man. Poisonous snakes are responsible for many deaths of man and domesticated animals in all tropical and some temperate regions.

The marine turtle, *Chelone mids*, found in tropical waters of the Atlantic, Indian and Pacific oceans, provides the best of all soups; several other forms found in fresh water are often eaten, the most familiar of these being the terrapins, of the genus *Chrysemys*. The eggs of various species are also eaten by uncivilized peoples.

The skins of crocodiles, and of certain of the larger lizards and snakes, are tanned and used as leather. This consists only of the cutis, the horny epidermis being removed. This leather is extraordinarily tough and wear resisting, and the presence in it of the papillae which underlie the scales gives it a most attractive surface. The pigment, or at any rate such of it as

FIG. 23.—SHOULDER GIRDLE OF A LIZARD AMBLYRHYNCHUS FROM BELOW, SHOWING THE RELATIONS OF THE CLAVICLES, INTERCLAVICLE PRECORACOID AND STERNUM TO ONE ANOTHER

is melanine, may remain in the leather and give it characteristic patterns. The use of reptilian leathers for ladies' shoes and handbags has become popular and led to the destruction of many of these animals. That of alligators, however, is derived in part from animals bred for the purpose.

Further information about reptiles will be found in the separate articles: CROCODYLIAN, DINOSAURIA, LIZARD, SNAKES, ICHTHYOSAURIA, PLESIOSAURUS, PTERODACTYL, TURTLE, etc., and in the general articles, EMBRYOLOGY, ANATOMY, PHYSIOLOGY, ZOOLOGICAL GEOGRAPHY, etc.

(D. M. S. W.)

Montesquieu in the 18th century of the idea of democracy as direct and small-scale, and his insistence that democracy was impossible in a larger state, which could be at best a representative republic. These ideas were studied and combined by a number of the founding fathers, and especially by James Madison, who used the term "republic" (1) as a technical designation for representative government as opposed to direct democracy and (2) to insist on the necessity for a system of checks and balances against the dangers of straight majoritarian decision in a legislature elected by majority on a single principle of representation. The insistence that republic is not synonymous with democracy either as direct democracy or as absolute majoritarian democracy, but rather is synonymous with constitutional democracy, is correct in the specific U.S. context, though that usage is a narrowing of the wider use of the term to denote any nonmonarchical regime. The guarantee to the states of the union of a republican form of government (in a nation whose given title deliberately excluded the designation republic) seemingly refers primarily to the more generic usage. It does not imply specific forms or checks, although some later extensions to the states of limitations on the federal government by guaranteed individual rights might be taken inferentially to imply more specific connotations of republican, even though those extensions were not, in constitutional interpretation, in any way related to that guarantee.

BIBLIOGRAPHY.—Charles A. Beard, *The Republics: Conversations on Fundamentals* (1913); Zera S. Fink, *The Classical Republicans* (1945); H. L. A. Fisher, *The Republican Tradition in Europe* (1911); Henry Mann, *Ancient and Medieval Republics* (1879). (T. I. C.)

REPUBLICAN PARTY, THE, in the United States was organized in 1854. Intense opposition in nonslave states to the further extension of the slavery system, and the breakdown of the compromise policy of Henry Clay, with the Kansas-Nebraska bill and repeal of the Missouri Compromise as the incidental causes, brought the party into being. The first actual meeting was possibly the one at Ripon, Wis., Feb. 28, 1854. The first convention was held at Jackson, Mich., July 6, 1854. All opposed to slavery extension were welcome. An informal gathering, national in scope, meeting in Pittsburgh, Pa., Feb. 22, 1856, planned the first national convention, which assembled in Philadelphia, Pa., June 17.

The chairman, E. D. Morgan of New York, declared the party's purpose to be to determine "not whether the South is to rule or the North . . . but whether the broad national policy our fathers established, cherished and maintained is to be permitted to descend to her sons."

Opposition to slavery extension and to polygamy, the imperative necessity of a railroad to the Pacific ocean, and approval of congressional appropriations for improvement of rivers and harbours were the platform subjects. Gen. John C. Fremont of California and William L. Dayton were the nominees, but were defeated after a vigorous campaign. Many events rapidly consolidated and intensified the anti-slavery movement, and on May 16, 1860, probably the most historic of all Republican national conventions assembled in the "Wigwam" at Chicago, Ill. It established a majority rule for nominations in contrast with the Democratic two-thirds. Threats of secession were denounced by the platform, which favoured restriction of slavery, opposed reopening the slave trade and favoured a protective tariff. Abraham Lincoln was elected president, Hannibal Hamlin vice-president. The story of the Lincoln administration is very largely the story of the Civil War. Preservation of the union at any cost was Lincoln's policy, and emancipation and other policies were largely incidental. During the war, however, the Republican congress found time to organize a national banking system under the National Bank act (Feb. 25, 1863); to pass a high tariff law and internal revenue act; and to take steps toward the construction of the first transcontinental railway. Despite earlier doubts, the result of opposition to the extent of the war and its terrific cost in life, President Lincoln was renominated by acclamation and re-elected in 1864. Andrew Johnson of Tennessee being selected as vice-president to secure the border states' support. The war was continued to a successful conclusion, but the assassination of Lincoln, who died on April 15, 1865, quickly terminated the celebrations of victory.

Reconstruction.—Johnson's outstanding problems, and those of the two following administrations were concerned with the so-called "reconstruction" of the seceded states. A marked difference of opinion as to the treatment to be accorded these states developed. Johnson's policy was not rigorous to the extent demanded by powerful congressional leaders. The result was a conflict between the executive and congress, culminating in Johnson's impeachment and acquittal by one vote.

"Let us have peace" was the slogan under which Gen. Ulysses S. Grant was elected president in 1868, with Schuyler Colfax of Indiana as vice-president. The problems of reconstruction, the extension designed to enforce provisions of the 14th amendment and the signing of a treaty with Great Britain (1871), called the treaty of Washington, which made provisions for settling diplomatic controversies between the two countries, were outstanding features of Grant's administration. The senate refused to ratify a treaty to annex Santo Domingo.

In 1872 certain Republicans opposed Grant's re-election and a new party, known as the Liberal Republican, nominated Horace Greeley to run against him. The Democratic national convention endorsed Greeley, but only six states were carried by the fusion ticket. Closest of two troubled years, with panic and scandal, there was much of credit in constructive achievement and U.S. foreign policies won respect abroad. In 1874 President Grant vetoed an inflation bill and a year later approved the resumption of specie payments.

Making capital out of scandals and the slogan, "Turn the rascals out," the Democratic party won the house in 1874 and almost won the presidential election of 1876. Rutherford B. Hayes of Ohio, Republican nominee for president, won after an electoral commission, specially created, had decided one of the most bitter political contests.

William A. Wheeler of New York became vice-president. President Hayes completed reconstruction in the south by withdrawing federal troops, a policy which brought him northern criticism because immediately after the troops were withdrawn Democratic leaders in southern states inaugurated the policy of Negro disfranchisement. Specie payments were resumed.

Domestic Questions.—James A. Garfield of Ohio was elected president in 1880, and upon his assassination in 1881, Chester A. Arthur of New York succeeded. Enactment of a national civil service law, establishment of the bureau of labour, two-cent first-class postage rates, and the beginnings of a new navy were brought about. The campaign of 1884 was most bitter in personal recriminations, both nominees, James G. Blaine, Republican, and Grover Cleveland, Democrat, suffering unparalleled attacks. Certain Republican elements refused to support Blaine, and at the end one famous phrase, "rum, Romanism and rebellion," lost for him the state of New York by 1,749 votes and he consequently lost the electoral college.

In 1888 Benjamin Harrison of Indiana defeated Cleveland, and Levi P. Morton of New York became vice-president. The tariff was a chief issue, but enactment of a higher rate bill, known as the McKinley act, was delayed until just before the election of 1890. It was unpopular and an overwhelming Republican defeat followed. The Harrison administration was noted for enactment of the Sherman Antitrust law, additional coinage of silver, drainage of several new states, among them Wyoming with the first provision for woman suffrage, and the famous Red enforcement of new rules in the house designed to prevent minority obstruction.

Personal dislike of the president by certain prominent leaders was a factor in bringing about Harrison's defeat for re-election in 1892, when Cleveland was returned to office with his party in control of both houses of congress for the first time since the Civil War. One of the worst panics and unemployment periods in U.S. history occurred and a lower tariff bill was enacted. The tariff was included in the Republican platform as an issue in the campaign of 1896, but as this battle approached, much greater prominence was given the question of the coinage of silver in relation to gold. William McKinley of Ohio was nominated by the Republicans on a gold standard platform, with Garret A. Hobart of New Jersey, vice-president. William Jennings Bryan of Nebraska won the Democratic nomination and stood upon the issue of free coinage of silver at the ratio of 16 to 1. McKinley won. Soon after he took office, higher protective rates in the Dingley bill were enacted. There was a tremendous revival of business and general prosperity during his administration.

Expansion Abroad.—The outstanding event of the McKinley administration, however, was the war with Spain over Cuban independence. As a result, the United States acquired the Philippines, Guam, and other possessions; Hawaii was annexed. The policy of continental isolation came to an end with this expansion, and citizens of the United States began to take an interest in problems abroad. With McKinley's assassination, after his second year in office, the story of New York became president, and he was also the successful candidate in 1904. One of the most popular and vigorous men ever in the presidency, Roosevelt adopted a number of strong policies: emphasis on conservation of national resources; beginning of the Panama canal; enactment of legislation for pure food and meat inspection; enlargement of the functions of the Interstate Commerce commission so it could regulate railway rates against discriminatory practices; settlement of the anthracite coal strike, intervention to bring peace in the Russo-Japanese War; creation of a navy secretary commission; and sending of the U.S. fleet around the world. Seldom has a president or an administration promoted so many issues that appealed generally to the people.

William Howard Taft of Ohio was elected president in 1908 and James S. Sherman of New York, vice-president. A new tariff law failed to appeal to the people as making good party pledges for lower rates, and a Democratic house was elected in 1910. The house was the scene of a so-called war against Cannonism, with modified powers for the speaker resulting. The 17th amendment, providing for the making possible a national income tax law, was submitted, and the parcel post

system was established. A division of the party came between the followers of Roosevelt and Taft in 1912, and the formation of the Progressive party with Roosevelt as leader contributed to the election of Woodrow Wilson, Democratic candidate for president in 1912. The Democrats won control of both houses of congress and retained it for four years for the first time since 1860. A lower tariff bill was enacted and the federal reserve system was created.

World War I.—World War I occupied the attention of the world from 1914 to 1918. The rallying cry, "He kept us out of war," proved sufficient to re-elect Wilson in 1916, but the Democrats suffered losses in membership in both houses of congress. When President Wilson asked for participation of the U.S. in the war in 1917, the Republicans joined Democrats in support of the war program. Wilson appealed to the country for a Democratic congress in 1918, but the Republicans gained control of both houses in the 66th congress—by a narrow margin in the senate but by a decided majority in the house. The president went to Europe and participated in the treaty negotiations at Versailles; his influence caused the incorporation in the treaty of provisions for a League of Nations. The Covenant of the League was considered by numerous leaders, some Republicans, some Democrats, as failing to protect U.S. interests, but proposed clarifying reservations were refused by President Wilson. A long fight resulted, and the issue was projected into the campaign of 1920. The result was a Republican victory, electing Warren G. Harding of Ohio, president, and Calvin Coolidge of Massachusetts, vice-president.

President Harding's administration made a separate peace treaty with Germany and Austria, summoned the naval arms limitation conference in Washington, made vast reductions in government personnel, established the budget system and generally emphasized the need of national economy. Loans were made to relieve agriculture and a higher tariff law was passed.

Depression and World War II.—The economic depression that followed the end of World War I was deep and long. The country was in a state of economic collapse, and the government was unable to do much to help. The depression was caused by a combination of factors, including the loss of European markets, the overproduction of goods, and the failure of the Federal Reserve to provide enough credit. The depression was not relieved until the start of World War II, when the government's war effort stimulated the economy and created millions of new jobs.

In 1936 the Republican candidates, Alfred M. Landon of Kansas and Frank Knox of Illinois, met overwhelming defeat, carrying only two states, Maine and Vermont, in the electoral college. In 1940 the candidates, Wendell L. Willkie of Indiana and Charles L. McNary of Oregon carried ten states. The election of 1944 also was lost, the candidates being Thomas E. Dewey of New York and John W. Bricker of Ohio, who won only 12 states. In 1946, however, the Republicans gained majority control over both the senate and the house of representatives for the first time in 16 years.

In 1948 the Republican national convention again nominated Dewey for president, with Gov. Earl Warren of California for vice-president. In spite of vigorous opposition, Pres. Harry S. Truman was nominated to succeed himself, with Alben W. Barkley of Kentucky for vice-president. The public opinion polls forecast a Republican victory, but President Truman entered upon a remarkable personal campaign in all parts of the country. The result was an unprecedented "upset," with Truman carrying 30 states and Dewey 16, while the electoral vote was Truman 303, Dewey 180 and J. Strom Thurmond 39.

Republican Victory of 1952.—At the Republican convention of 1952 in Chicago, Gen. Dwight D. Eisenhower was nominated on the first ballot for president, with Sen. Richard M. Nixon as his running mate. The Eisenhower-Nixon ticket carried the nation on Nov. 4 by a landslide, winning 442 of the 531 electoral votes.

REQUEST, LETTERS OF. The legal terms "letters rogatory," or "of request" (*commissio rogatorie*), express a request made by one judge for the assistance of another in serving a citation, taking the deposition of a witness, executing a judgment, or the doing of any other judicial act. The only trace of such a practice to be found in England or the United States, independent of statutory enactment, is in the admiralty doctrine that

the sentence of a foreign court of admiralty may be executed on letters of request from the foreign judge or on a libel by a party for its execution. See the authorities collected by Sir R. Phillimore in *The City of Mecca*, 5 P.D. 28. The British and United States courts issue commissions to private persons, generally, however, to consular officers, but sometimes to foreign judges in their private capacities, for the purpose of taking the depositions of witnesses. Many countries object to this process and require letters of request, which have to be forwarded through diplomatic channels (see *Rules of the Supreme Court*, O. 37). In ecclesiastical law, letters of request are issued for the purpose of sending causes from one court to another. Letters of request are also issued for other purposes: to examine witnesses who are out of the jurisdiction, to enforce a monition, etc.

REQUESTS, COURT OF, originally a committee of the king's council in England. Petitions of poor persons were heard by the justices in eyre and on the fall of the eyre were referred by the council to the chancery. By an Order in Council of 1390 these petitions were transferred to a committee of the council and the lord privy seal became its president. At first the court followed the king, but about 1516 Wolsey assigned to it a permanent seat in Whitehall, when it became known as the court of Whitehall or the court of poor men's causes. Lastly, it obtained its official title of the court of requests. The judges were at first those privy councillors who happened to be present, together with judges and masters as assessors. Eventually four privy councillors, known as masters of requests, were appointed at fixed salaries. See I. S. Leadam, *Select Cases in the Court of Requests* (Selden Society, 1898).

REQUISITION OF SHIPPING: see SHIPPING, MINISTRY OF; SHIPPING CONTROL COMMITTEE.

REDOS (rêrdôs), an ornamental screen of stone or wood built up, or forming a facing to the wall behind an altar in a church. Redoses are frequently decorated with representations of the Passion, niches containing statues of saints, and the like. In small churches the redos is usually replaced by a hanging or paravent behind the altar, known as a dossal or dorsal. (See also ALTAR.) The use of the word redos for the iron or brick back of an open fireplace is obsolescent.

RESACA DE LA PALMA, a battlefield of the war between Mexico and the United States (1846-48), about 4 mi. north of Brownsville, Texas. On the morning of May 9, 1846, the day after the battle of Palo Alto, which had been indecisive, the United States troops under Brig. Gen. Zachary Taylor, ready to renew the conflict, were surprised to see the column under the Mexican Gen. Mariano Arista disappearing through the chaparral toward Matamoros. Unable to pursue with more than a few hundred men, because he must first put his wagon train in a state of defense, Taylor was slow in following his adversary. The latter had entered a dense growth that continued interruptedly to the Rio Grande, 7 mi. to the south.

After having marched about halfway through the thickets, Arista disposed his command behind an old river channel which crossed the road at right angles. The bed (Resaca de Guerrero) was full of ponds and mud, impassable in many places. The Americans, about 1,700, came upon the Mexican guns planted in the road and almost immediately thereafter there was a collision. The dense growth of mesquite and cactus made it impossible for companies to see each other and it was difficult for Taylor's artillery to operate. His soldiers, losing touch with one another, floundered and hacked their way toward their enemy. Although there was little direction or plan to the encounter, the discipline and training of his subordinates kept them pressing forward. The vigour of the U.S. troops in their assault dismayed the Mexicans. When one of Arista's flanks was accidentally turned, a panic seized his whole force. It is estimated that about 4,000 out of some 5,000 succeeded in reaching the river where many were drowned in crossing. The American loss was comparatively small.

RESCHEN SCHEIDECK. This Alpine pass is in a way the pendant of the Brenner Pass, but leads from the lower Engadine to the upper valley of the Adige. Near the summit (4,902 ft.) is the hamlet of Reschen, while some way below is the former hospice of St. Valentin auf der Haid, mentioned as early as 1140. Starting from Landeck, the motor road runs up the Inn valley to Pfunds, whence it mounts above the gorge of Finstermünz to the village of Nauders (271 m.) joining the road from the Swiss Engadine (534 m. from St. Moritz). Thence it mounts gently to the pass, and then descends, with the Adige, to Mals (151 m.), whence the pass is sometimes wrongly named Malserscheide. The road now descends the upper Adige valley, or Vintschgau, past Meran (374 m.) to Botzen (20 m. from Meran) where the Brenner route is joined.

RESEARCH, INDUSTRIAL. Industrial research aims at applying to industry the truths wrested from nature by workers in science. In 1893 Sir W. Anderson wrote "The days are past when an engineer can acquire himself respectably by the aid of mother wit alone or of those constructive instincts which in the past led our predecessors to such brilliant results." Each year makes the truth of his words more manifest; industrial research is one important stone in the foundation of our modern civilization.

But appreciation of this truth has been slow of growth, at any rate in England. In Germany during the later years of the 19th century the Reichsanstalt and the Materials Prüfungs Amt were founded, and their work, along with investigations at technical institutes, had no small effect on German industry. The beginning of the 20th century saw the establishment of the National Physical Laboratory in Great Britain, followed almost immediately by that of the Bureau of Standards at Washington, while in Paris there was the Laboratoire Central d'Electricité and much renewed activity at the Laboratoire d'Essais in the Conservatoire des Arts et Métiers. But it needed the shock given by the World War before the truth of Sir W. Anderson's words was fully grasped.

Industrial research does not necessarily differ from so-called pure research in its methods; it is the object with which the investigation is made that constitutes the difference; and of course much work is necessary before the laboratory discovery, or the brilliant intuition of the inventor, verified by striking experiments, can be translated into the practice.

Mendel's Work.—It was the desire for knowledge, pure and simple, that led the Abbé Mendel in his monastery at Brinn to unravel some of the laws of heredity (g.v.) by crossing various kinds of peas. When, at an agricultural institute, the laws that he discovered and the methods he employed are utilized to improve the breed of cattle or to produce new and more valuable forms of wheat, the research has become industrial.

The Structure of Matter.—At present physicists in many countries are investigating the properties of matter by X-ray analysis, determining the forms of lattice in which the atoms which constitute the substance are arranged and endeavouring to draw conclusions applicable to all matter; this is a great work of pure research. The metallurgist employed in some works or industrial research laboratory seeks to use the results of the physicist and the methods which have been devised to enable him to learn, for example, why steel is hardened by quenching, what is the cause of the deleterious effect of phosphorus on copper, or why cast metal which is brittle can be made soft and ductile by heat treatment and mechanical work. This is industrial research. Such a worker may carry his investigations further in order that they may be of use to industry. In his laboratory some method devised for making and treating a new and valuable alloy works perfectly or some instrument designed to register the course of a factory process appears foolproof and without a fault; in the factory the alloy cannot be worked or the instrument fails under the first real test; it is his business to find out why; to make the advances of science—advances due in part to his own researches—available for industrial purposes.

Here a distinction should be drawn between the research laboratory of a works and the works laboratory; where both exist

there may well be close co-operation, and possibly joint control, but the spheres are distinct. In any modern factory a works laboratory of some sort is essential, to check the purity of the materials employed and to ensure that the product is up to standard; an engineering works will have its chemical laboratory for this and similar purposes, its testing laboratory where the strength and character of its manufactures are sampled before they are put upon the market; but such work is not research; though it often may indicate where research is necessary, and lead up to original investigations of high value to the firm.

The works manager knows that for success the temperature at some point in a complicated process must be kept within narrow limits, whereas during other operations large variations of temperature have little effect. Samples which fail come to the works laboratory for examination, and inquiry shows that the temperature limits at this critical stage have been exceeded. Such an occurrence naturally leads a competent chemist to inquire what is the nature of the action which takes place at this critical temperature; how does the product produced, when the temperature limits are over-stepped, differ from the proper article? This inquiry may lead to a long and intricate investigation with results of the utmost importance to the firm. It may be found, for example, that a slight change in the composition of the material will render the close limits unnecessary and will reduce greatly the care and attention required for the manufacture. The problem has become one for industrial research, not merely for routine testing, and the consequences of that research have proved to be simplification of manufacture and cheapening of the product.

In Great Britain nearly 50,000,000 people must be supplied with food, mostly brought from beyond the seas, and this food must be paid for with the products of industry at home, by the goods manufactured in great part from materials purchased from abroad but dependent on the coal and iron of English mines and by the knowledge and skill of English manufacturers. It is of the utmost importance that the high quality of those goods should be maintained, the methods of their manufacture improved and the costs of production reduced. In the words of a recent report: "Scientific and industrial research is an essential factor in the national effort on which the continued maintenance of our present population unquestionably depends." And these words, though used here for England, apply to the other nations of the world as well.

And now we come to consider the means taken to promote industrial research and its present position and work in various lands.

These means are various; the state in a number of instances has organized research laboratories devoted mainly to industrial problems; large private firms have established similar laboratories under their own control, while attempts have been made by the formation of research associations to combine the efforts of a number of firms concerned in the same industry. The universities, too, and technical colleges have aided the endeavour by organizing more fully the teaching of science and giving facilities for the training of research workers.

Germany.—It needed a catastrophe to produce the results which have been attained. The Reichsanstalt in Berlin was a direct outcome of the war of 1870. Established in two divisions, the one devoted to pure science, the other to its applications, its founders realised the close interdependence of the two, and while the first division dealt to a large extent in questions bearing on the fundamental units and standards of measurement whether in heat, electricity, light or any other branch of physics, the second division was concerned mostly in the application of the principles which resulted from these investigations to the advancement of German industry and manufacture.

At the same time technical colleges were established in a number of centres; of these, perhaps the colleges at Charlottenburg and Darmstadt were the most important, and from their professors and students came a stream of scientific facts and discoveries, many of great value to industry, which were eagerly seized upon and assimilated by men at the head of great industrial concerns who had realised that science was the foundation of their success.

In their own factories these men were no less active and far-

seeing. Charlottenburg and the Materials Prüfungs Amt at Gross Lichterfelde which developed from it taught the engineer and the metallurgist the value of research. Its professors devised delicate instruments for use in investigating the properties of materials; the Martens Extensometer is an example. Sorby, of Sheffield, in 1864 was the first to investigate the structure of metals and alloys by the aid of the microscope, but his work was not pursued until, at a later date, Osmond in France and Martens in Germany took up the study independently and showed its importance to the industrialist.

In electrical science, also, the work of the Reichsanstalt had a marked effect and the great electrical firms—the Allgemeine Electricitäts Gesellschaft, Siemens and Halske and others—established research laboratories to develop for their own purposes and private benefit the results of scientific investigations.

Nor should the great chemical firms be forgotten. Perkin, in England, was the founder of the modern dye industry, but it was in Germany that this teaching first bore practical results. The Badische Anilin Fabrik and other similar works were founded and huge sums were spent in developing new methods and inventing new dyes. Artificial indigo took the place of the natural product, with the inevitable result to the Indian industry. Germany had learned the lesson, and industrial research promised, unless other countries woke up, to give her the leading position among the manufacturing nations of the world.

Great Britain.—In England, until towards the end of the 19th century, the danger was hardly appreciated. At meetings of the British Association and elsewhere Sir O. Lodge and others had pointed out the value of the Reichsanstalt to Germany, the need that England should have a similar institution. In 1900 the National Physical Laboratory began in a small way—the expenditure during the first year was £5,479—in the old buildings of the Kew Observatory at Richmond. In 1901 the work was transferred to Bushy House, Teddington, with a staff of eight scientific assistants and six attendants in addition to the director. The scientific character of its work was secured by placing the ultimate control in the hands of the Royal Society, while a close connection with industry was maintained by having representatives of the great engineering societies on its governing body. The laboratory, at the time the only public institution in the country devoted to the application of science to industry—to industrial research—grew slowly and prospered for the next 12 or 14 years, and when the World War came, it was in a position to be of material service to the country.

About the same time, the British Engineering Standards Committee was founded, chiefly at the instance of Sir John Wolfe Barry, who had realised the loss caused by the infinite number of standards used by engineers and the advantages to be gained by a system based on accurate measurement and a careful investigation of the properties of the materials employed in structures. In this work the National Physical Laboratory co-operated very fully. Meanwhile at an earlier date industrial research of importance had gone on in a few laboratories attached to firms in Sheffield and elsewhere. The work of Sorby on the micrographic structure of metals has already been referred to and at a later date Roberts-Austen of the Mint utilized this method of inquiry in his investigation of a broken rail which had led to a serious accident on the Great Northern Railway. Manganese steel was produced from the laboratory of Sir Robert Hadfield in 1882 as an outcome of a scientific inquiry into the properties of alloys; many results of high value have since come from the same source.

France.—In France, work of value was being done in various places; the Laboratoire d'Essais and the Laboratoire Central d'Electricité both contributed. The metallurgical work of Osmond and Le Chatelier was of marked importance, while the discovery of the special properties of Invar—an alloy of nickel steel—by Guillaume has proved of value in many industries.

International Standards.—One of the marked consequences of industrial research has been the realisation of the importance of international standards of measurement, and as a result international co-operation between the standardizing laboratories in various countries and other bodies concerned with standards has

become necessary. From this need arose the Bureau International des Poids et Mesures at Sèvres and various international associations such as the International Electrotechnical Association or the Association for Testing Material. In 1908 the British Government summoned an International Congress in London at which the system of electrical units, now universal throughout the world, was adopted.

War Problems.—This is not the place to give any account of the influence of science on war; experience showed it to be vital and the phrase that Science won the War, interpreted to mean that without science the War would have been lost, only expresses the truth. In the Allied countries on both sides of the Atlantic, men and women were at work solving problems of vital importance. Facilities for research were open to them, funds undreamed of in peace time were at their disposal, and the results of their endeavours contributed to a more general acceptance of the view that in peace time industry would benefit in the same way from scientific inquiries wisely guided and pursued.

Department of Scientific and Industrial Research.—And so, in Great Britain as elsewhere, a movement was started to organize in some more definite way the connection between science and industry. The establishment of the Department of Scientific and Industrial Research was the outcome of this movement. This was announced by Lord Crewe, Lord President of the Council, at the end of 1916 in reply to a deputation from the Joint Board of Scientific Societies headed by Sir Joseph J. Thomson, P.R.S. An advisory council of scientific men was established and the sum of £1,000,000 was placed at the disposal of the department to be used in the application of science to industry.

The financial responsibility for the National Physical Laboratory, with a staff which before the end of the War had grown to 600, was transferred to the department; boards were set up for fuel research, food investigation, building research and various other subjects, while a number of co-ordinating bodies were established to deal with researches of importance to Government departments, especially those bearing on industry. These researches are carried on either in special laboratories or at one or other of the national laboratories; the Geological Survey and Museum became one of the activities of the new department, which thus undertook the task of guiding and supervising the various official agencies for making the advances of science of service to national progress. The department also aids the work of the Aeronautical Research Committee which—at first as the advisory committee for aeronautics—has contributed in no small degree to the science of aviation.

Co-operative Research.—But the department has done more than this. In Germany and America many of the great industrial firms have their own research laboratories; reference has already been made to some of the results on German industry. But research laboratories are costly; in many industries in England the firms concerned are small, a private research laboratory is too expensive to be contemplated, besides a number would produce wasteful overlapping. Hence the attempt was made to introduce a system of co-operative research. In an effort to lead manufacturers to rely more on scientific results, research associations have been set up. Each of these consists of a body of men engaged in the same industry who associate themselves for the purposes of research bearing on their industry. Each association has its own director of research, or similar official, under whose guidance the work planned by its council is carried on either in their private laboratory or by arrangement at the National Physical Laboratory or in the laboratories of some university or technical college.

The work is financed in part by the associated firms, in part from the million fund, usually on a pound to pound basis guaranteed under certain conditions for five years and with a limit of £5,000 a year to its amount. In 1927 there were 24 such associations in existence; the balance in the million fund is now £352,292; a substantial part of this is required to complete the payments already promised. In a number of cases the first five years for which the grant was made have elapsed and the department, with a view to determining its future course, has arranged for a report from some independent body on the work and progress in each

case. In a recent report to the committee of the Privy Council responsible for the work of the department, the advisory council writes of the associations:

"We have no doubt that they have already produced results of financial value far greater than their whole expenditure and have been instrumental in introducing scientific methods and encouraging scientific spirit in industry."

It is clear from the general tenor of these reports that 5 years is insufficiently long even under the most favourable conditions to set a research association on its feet and make it independent of government assistance. To devise a programme, collect an efficient staff and obtain results all take time. Besides, there is much educational work to be done; half-hearted supporters need to be converted by results before they will contribute freely; trade rivalries tend to prevent complete co-operation; trade has been bad and returns barely sufficient to keep old ventures going; there has been little to spare towards an expenditure of whose value the manufacturer is only half convinced. And so the department has considered the steps to be taken to maintain the work for some years to come and, in the case of some important associations, has settled the terms of future grants (*see* report of the Department for 1925-6).

Training of Workers.—But there are other ways in which official support is being given to industrial research, and among these the schemes for training research workers is most important. Under this scheme young graduates are assisted to carry out researches under the guidance of some competent professor, while, in a number of cases, funds have been granted to prominent workers to enable them to pursue inquiries of importance.

The royal commission for the exhibition of 1881 administers for the advancement of education and research funds arising from the balance left when the exhibition closed. For many years past its scholarships and studentships have been of great value. The commission has inaugurated a number of Industrial bursaries given on the recommendations of the universities and technical schools to men trained in science who were prepared to enter, as apprentices or students, engineering or other works. In this way, a stream of trained workers in science is provided for industry.

Private Research Laboratories.—Before concluding, reference should be made again to the research laboratories of prominent firms, in England, the laboratory of the General Electric Co. at Wembley occupies a leading place; but it is to Germany and America that we turn for striking examples of what a works research laboratory can do (*see* below). (R. T. GL.)

THE UNITED STATES

The history of American technology reveals plainly that within the past five or six decades, and mostly within the last 40 years, manufacturing practice has progressed vastly more than in any previous era. In all the important branches of industry empiricism has been supplanted by industrial research. It was estimated in 1939 that there were at least 30,000 scientists and engineers engaged in research on behalf of the industries of the United States. Assuming this figure to be approximately correct, as it undoubtedly is, over \$180,000,000, probably \$200,000,000, is being expended annually in supporting industrial research. About half of this amount is spent on chemical laboratory investigations, most of which are conducted by companies in their own plant laboratories.

Industrial Research by Companies.—The largest research establishment in the United States is the Bell Telephone Laboratories, Inc., in New York city, which employs about 2,000 physicists, chemists and engineers for original investigation and development of new forms and improvement of existing forms of apparatus and equipment for electrical communication. Next in collective size are the twenty-three laboratories of E. I. du Pont de Nemours and Co., Wilmington, Del., wherein about 1,000 chemists and engineers are studying problems of the heavy chemical, paint, lacquer, solvent, plastics, textile, dye, rubber, and explosive industries. Other great laboratories are operated by Aluminum Company of America, New Kensington, Pa.; Dow Chemical Co., Midland, Mich.; Eastman Kodak Co., Rochester,

N.Y.; General Electric Co., Schenectady, N.Y.; Lynn and Pittsfield, Mass., and Cleveland, O.; General Motors Corporation, Detroit, Mich.; Gulf Research and Development Co., Hamarville, Pa.; Hercules Powder Co., Wilmington, Del.; Monsanto Chemical Co., St. Louis, Mo.; RCA Manufacturing Co., Harrison and Camden, N.J.; Standard Oil Development Co., Linden, N.J.; and Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa., and Bloomfield, N.J.

In the last 30 years numerous companies have taken advantage of the *industrial fellowship system* of Mellon Institute of Industrial Research as a means of solving problems in manufacturing practice. In 1939, 78 fellowships were being sustained by as many different companies, largely chemical manufacturers, while 7 more fellowships were being supported by trade associations.

About 110 individual companies in the field of chemical industry are making research grants to educational institutions. Chief among them are E. I. du Pont de Nemours and Co., supporting 24 fellowships. Other firms making many grants to universities are as follows: E. R. Squibb and Sons, 17; Merck and Co., 14; Standard Oil Co. of California, 13; Upjohn Co., 11; and Standard Brands, Inc., 10.

There are about 200 college laboratories that are used not only for purposes of instruction, but also to a considerable extent for industrial research work and for commercial testing.

A considerable number of companies, mostly small concerns that have no laboratories of their own, or larger companies that encounter few problems or are engaging in research for the first time, are regular or occasional clients of consulting laboratories. There are about 250 of these commercial laboratories in the country, and some of them are strongly staffed and excellently equipped for scientific investigation, particularly in specific industries. For example, a firm of consultants, which has a main laboratory and also four branches in other cities, employs 70 scientists and their assistants for varied research. Another firm operates twelve laboratories. Most of these commercial organizations do testing as well as research work.

Trade Association Research.—The U.S. Department of Commerce has expressed the opinion that "among constructive activities of trade associations none is more fitting nor more profitable than scientific research." The study of production and distribution problems to evolve more efficient and more economical methods has in fact become a leading association activity. We shall describe here associative industrial or technological research, and not commercial or economic investigations, which, while entirely different in nature, are often related to the former.

Five different procedures are being applied with success in conducting associative industrial research. (1) A number of associations are co-operating with Government departments and bureaus in accordance with the *research associate plan*. (2) Other associations are sustaining scientific investigations in Mellon Institute of Industrial Research at Pittsburgh, in Battelle Memorial Institute, Columbus, Ohio, or in other research foundations. (3) Some associations are supporting fellowships or scholarships in educational institutions. (4) Still other associations are carrying on research in commercial establishments, such as the laboratories of professional consultants. (5) A few associations have founded their own laboratories.

The Research Associate Plan.—For many years the scientific and technical research facilities of various Governmental departments have been available, by legislative enactment, to duly qualified workers (Supp. Rev. Stat., 2, 71-2, 1532; Stat. L., 27, 1010; Bureau of Standards Circular No. 296). This plan has been developed especially in the National Bureau of Standards, where there were in 1939 80 research associates employed by associations or specific groups. Each associate is subject to the bureau's regulations and has most of the rights and privileges of the members of the bureau staff. The investigational results are immediately accessible to the industry concerned and are published by the bureau. Specialists on the bureau's staff of over 900 may be consulted by the association and its research worker, and the latter is also permitted to use the scientific equipment, special laboratories, and shops of the institution.

In general, this flexible, closely co-operative plan has been successfully applied. There are in fact several notable instances of economic savings to technology from research in the bureau. It has been reported (Department of Commerce, Domestic Commerce Series No. 20, "Trade Association Activities," 1927) that \$15,000,000 is being annually saved to industry and the public from the bureau's brake-lining research, that the annual savings from its tire investigations amount to \$40,000,000, and that the motor-fuel studies are saving \$100,000,000 each year. Research in the bureau also eventuated in the founding of a dextrose industry in the U.S. The following are among the investigations in progress: constitution of petroleum, colour standardization, dental materials, silver, nonferrous alloys, soldered plumbing fittings, aviation lighting, railroad signal glasses and Portland cement.

The Bureau of Chemistry and Soils and the Forest Products Laboratory of the Department of Agriculture and the Bureau of Mines of the Department of Commerce have also advanced technology by researches on behalf of various industries. The Bureau of Mines is conducting various investigations in mining, metallurgy, health and safety, and on the economics of the production, preparation, and utilization of minerals. The research laboratory of the American Society of Heating and Ventilating Engineers is located in the Pittsburgh station of this bureau. The laboratory of the National Advisory Committee for Aeronautics is a central research plant serving the industries concerned and Government alike. Certain researches of the Public Health Service of the Department of the Treasury—investigations of dusty trades, sewage disposal, water purification, illumination of buildings, and motor fuels—have also benefited industry.

The Industrial Fellowship System.—Some of the research of Mellon Institute is sustained by associations of manufacturers, according to the institution's industrial fellowship system (see DUNCAN, ROBERT KENNEDY). These association fellowships pertain to acid recovery, air hygiene, anthracite, cotton, iodine, pearls, and refractories. The multiple fellowship of Air Hygiene Foundation of America represents a collective effort by 250 companies in behalf of employee health. Fundamental research in industrial health is nurtured and member companies are provided practical plant applications to prevent industrial illness. The multiple fellowship of the Cotton Research Foundation aims to make both basic investigations and practical studies of any subjects that carry the possibility of improving the cotton economy of the United States. The American Refractories Institute's multiple fellowship has been in continuous operation since 1917. Its incumbents have enriched both refractories technology and metallurgy by their studies of the evaluation of refractories for specific purposes and by the improvements that they have made in manufacturing and testing methods.

An association fellowship of this type enables direct research service to a number of industrial concerns instead of to an individual company. Its activities also give rise to stable relations of co-operation among the members of the association by the exchange of technical experience and research results. An association fellowship usually acts as a clearing-house of information for the sustaining organization, and gives technical assistance and scientific advice to the company-members. One of the prominent advantages of association research is that it enables a small manufacturer, who cannot afford to have a research laboratory of his own, to profit from the investigational work in the same way as a larger manufacturer. Association research reduces the cost factor to a minimum and thus promotes the welfare of manufacturers in the field concerned, without respect to size. Moreover, problems may be studied that require more time and expense than should be borne by a single manufacturer or company, in view of the wider application of the results. The correlation of research effort, such as is done in the fellowships supported by associations, prevents unnecessary duplication in scientific inquiries.

Association Fellowships in Educational Institutions.—This class of research has become important in many industrial fields. It serves to train technical specialists as well as to aid in solving production problems. Armour Institute of Technology, Purdue university, Ohio State university, Columbia university,

Iowa State college, and the universities of Illinois, Michigan, Wisconsin, Minnesota, Chicago, Cincinnati, and Pittsburgh are in the fore of the institutions that are encouraging industrial research by associations and also by individual companies. About 40 trade associations are now sustaining such investigational work. The American Gas Association has 14 fellowships and the American Petroleum Institute is making 19 similar grants.

Association Owned Laboratories.—Industrial research is not conducted in any set type of laboratory nor in accordance with any fixed plan. The nature of the problems, the financial support available and the uses to which the research findings are to be put determine the method. If problems are extensive and association members are so appreciative of the value of research that they will contribute to the building and maintenance of a laboratory, it is often advisable for an association to do its own research.

Co-operating Agencies.—The National Research Council serves as a general clearing-house of information on research work undertaken throughout the country. Its division of engineering and industrial research endeavours to co-ordinate the scientific resources of the nation as regards engineering and secures the co-operation of engineering agencies in which investigational facilities are available. It works in co-operation with the Engineering Foundation and various national engineering and technical societies. Associations or companies undertaking research may ascertain from the council what work has been done or is in progress along similar lines, thus avoiding duplication of effort.

The American Standards Association, the American Society for Testing Materials and the American Engineering Council are some of the organizations whose effectiveness depends in many cases on the collaboration that they receive from trade associations as well as individual concerns that carry on research.

Hamor, *Glances at Industrial Research* (1936, 246 pp.). (W. A. HA.)

PROCESSES

The fundamental factors underlying industrial research are: the need for making goods at less cost, of better quality, and in larger quantity. As incidental to the better utilization of available raw materials, industrial research has been responsible for the creation of new materials, new applications of old materials, and the creation of new industries. It is not possible to draw up a classification of industrial research which will satisfy all purposes, but in this survey the products have been grouped about the qualifications of the research worker and not upon the ultimate use to which the product may be put.

The conservation of natural resources has been one of the principal impulses for research in the chemical industry. By the process known as "cracking" almost twice as much gasoline may be obtained from crude oil as by the straight process of distillation. A process has been developed for making motor fuel from certain refinery gases which formerly were wasted. Refinement of gasoline has produced a motor fuel that eliminates engine "knock" attributable to the uneven burning of the mixture.

Great strides have been made in the creation of an entirely new industry in plastics through the perseverance of research workers. The development of a phenolic resinoid base for plastic materials encouraged a wide expansion of electrical devices through the provision of cheap and efficient insulating materials. When

cellulose fillers were added to this resinoid base many useful industrial applications were discovered in which materials requiring lightness, high finish, and mechanical strength were demanded. The use of mineral fillers has furnished materials less easy to process but which have high heat resistance and excellent water resistance. The latter property has resulted in the adaptation of the new materials for outdoor paint. Articles of considerable impact strength, such as automobile gear wheels, have also been made successfully from these plastics.

Paralleling this development has been the extensive research into the employment of cellulose as a base for plastics. Many articles of decoration and utility formerly made only in restricted quantities from natural products like amber, bone, wood, tortoise-shell, etc., are now made from plastic materials derived from cellulose. Durable toilet-ware in gay colours, electrical appliances, jewellery, lighting equipment, motion picture film, automobile accessories, and a thousand and one other useful things (not omitting the ubiquitous cellophane) have been produced in vast quantities at low cost.

One of the great advantages of the utilization of this plastic material is the existing wealth of raw material, much of which was formerly regarded as waste. An additional development has been the creation, after much research, of an improved safety glass. Cellulose nitrate and acetate had certain marked disadvantages as the plastic filling for safety glass, chief of which was their tendency to become brittle and to lose their effectiveness at temperatures below 20° F. A production drawback was the necessity for sealing all edges of the glass to avoid evaporation of the plastic and to prevent moisture from attacking it. The development of a polyvinyl acetal resin for the plastic film between sheets of glass has done much to remove these defects in laminated glass for safety purposes.

The same cellulose base which is used for the manufacture of plastics and artificial silk finds a new use in the making of artificial sponges. Wood pulp is steeped in strong caustic soda and then treated with carbon disulphide. The resulting mass is the familiar viscose. In the making of artificial sponges this viscose is mixed with a pore-forming material (fat, sugar, paraffin, or sodium sulphate dehydrate). The blocks of treated viscose are then placed in moulds within a chamber into which steam or hot air is admitted. This coagulates the viscose and melts the pore-forming material, leaving innumerable pores in the block. The finished material is lighter and absorbs more water than the natural sponge.

Under the stringent stimulus of the menace of economic or naval blockade, some countries have pressed forward research for the extraction of motor fuel from coal. While a certain amount of success has been achieved the resultant fuel is neither low in production cost nor high in octane rating. It is not suitable, therefore, for high speed motors.

Within recent years research has developed processes for combining the nitrogen in the air with hydrogen from water to produce ammonia, thus furnishing an inexhaustible supply of fertilizer to make the farmer independent of the rapidly diminishing Chilean deposits of sodium nitrate.

Camphor, which was formerly obtained (often at prohibitive prices) from Formosa, is now secured through a process by which turpentine from the common pine tree is converted into camphor.

Synthetic rubber combining all the elastic qualities of natural rubber and avoiding some of its disadvantages, such as deterioration due to exposure to sunlight and oil, is now produced from the common basic materials, coal, limestone, and salt. Although this synthetic rubber-like material was designed primarily for uses that natural rubber could not meet, it is comforting to several nations to know that, in the event of a major emergency, it can be produced from domestic raw materials, even though the production cost is somewhat higher than the average cost of natural rubber.

Reference has already been made to the new plastic materials adapted to the manufacture of toilet-ware. Similar advances have been made in the improvement in table-ware made of glass and china. The chemist has produced new durable colours for ceramics,

and a new glaze-like substance of plastic resin awaits industrial application.

One of the most far-reaching achievements of the industrial chemist was the creation of artificial fibres. The general process is much the same. The raw material is dissolved in a strong alkali, forming a paste. This paste is squeezed through fine holes, and the threads thus created are hardened in an appropriate bath. The raw material determines the nature of the finished product—cellulose is the basis for rayon, casein for artificial wool. Although the manufacture of synthetic wool has made no great progress, rayon has advanced by leaps and bounds and become a vast industry. Its early sleazy appearance has undergone a metamorphosis. Refinements in rayon fibre enable the manufacturer to provide a rich assortment of fibres. In fact, the dress and decorative fields have been so adequately supplied that research is now advancing the uses of rayon into more remote applications. Rayon cords are being used in the manufacture of automobile tires as substitutes for cotton.

The rayon fabric has been found to have a lower heat coefficient, an important feature when the effect of heat upon rubber is considered.

Research culminated in the achievement of the first synthetic textile fibre made from inorganic substances—nylon. Using coal, air and water as basic materials, research chemists developed an entirely new material of large molecular structure, in which orientation of the molecules in line ensures a considerable degree of elasticity.

Since the water resistance of this fibre is equal to that of silk, the combination of elasticity and waterproofing furnishes durability and makes the substance unique.

Its first commercial application was its substitution for animal bristles in brushes.

The absolute sterility and waterproof quality of nylon makes it particularly suited for toothbrushes. As production is flexible, the fibre may be manufactured with any diameter. A number of other comparable synthetic fibres were developed later.

Although it is not practicable to separate modern physics from chemistry and engineering, industrial research in such fields as energy, heat, motion, electricity, light, and sound is undertaken by men who are primarily physicists. Much industrial research of a purely physical nature has been undertaken in quelling dangerous or annoying vibrations in every branch of transportation using the internal combustion engine. A great deal of physical research is being directed toward the solution of problems in hydraulics, the strength of materials, physical metallurgy, mechanical and electrical engineering which will result in the improvement of materials and processes without any spectacular effect. Applied physics is used in the detection of ores and oil underground, and many physical laws are applied to new ways of sinking oil wells and in probing the ocean's depths.

In the field of communication the principal results have been achieved in the research development of efficient means of facsimile reproduction and television. Facsimiles transmitted by radio waves have already advanced to the stage in which a tabloid journalism of the air is within reach. After years of research, physicists and engineers have abandoned the mechanical scanning devices of early television, and have evolved a method of recording images upon a mosaic within a vacuum tube. The scene to be televised is focused by an optical system upon this mosaic, made up of globules which are in effect small photo-electric cells. On the mosaic the scene takes the form of a mass of small spots having varying degrees of light intensity. Scanning of the mosaic by means of an electron beam converts the light registered by each globule into an electric impulse. These impulses are amplified and used to modulate the transmitter, which, in turn, transmits the impulses by the medium of radio waves, to the receiver. In order to overcome the physical restrictions of transmitting ultra-short waves beyond the visible horizon, telephone engineers undertook the development of a cable for the linking of distant stations. The outcome has been the production of the so-called coaxial cable, suitable for the establishment of television networks resembling those of radio, as soon as the television industry is in a position to

acquire and to finance the laying of this cable in large quantity. Television has now reached the stage in which adequate reception is assured within a limited area about the transmitting station, but progress must be made in the commercial aspects of television before this form of intercommunication comes into general use.

Research which produced the photo-electric cell is now occupied with finding applications for it, replacing men in routine jobs, speeding manufacture, improving quality, ensuring standardization, and exercising remote control over mechanism. By means of the photo-electric cell electrical action can be brought to bear instantly on what it sees, at any distance, and at any time without the interposition of human hands. The future development of this device carries with it a vast range of future economic effects.

Research into the polarization of light offers a solution to the vexed question of glaring headlights on automobiles. Universal adoption of this invaluable safety device must, however, wait upon State legislatures passing laws that impose penalties upon owners of cars who drive with dazzling headlights. Meanwhile, pending the passing of such legislation, other applications for this laminated glass which polarizes light waves are being exploited. Between two sheets of glass is a layer of transparent plastic with millions of uniform needle-like crystals in colloidal suspension. All the crystals are oriented in the same direction, so that light waves, instead of vibrating in all planes, are controlled within one.

It has applications in sunglasses, windows and photography. A valuable industrial use has been found for it in the examination of strains and stresses of materials. A model of the part to be tested is made of phenolic resinoid plastic. This is subjected to a proportionate stress, and the strain is revealed by the distribution pattern of the polarized light transmitted by the model.

Elsewhere in the field of optics research has produced many refinements in photography. Noteworthy has been the development of the high-speed camera and its employment in the study of strains and stresses in rapidly revolving machines. Optical systems have been further refined and applications ranging from the new 400-inch telescope to the improvement of lenses for cinema cameras, have been developed. Numerous improvements in film emulsions have increased the flexibility of photography.

A new form of indoor and outdoor lighting has been introduced as a result of research into the properties of fluorescent materials. Glass tubes, filled with mercury vapour under low pressure, have their inner walls painted with a fluorescent material. On turning on the light-switch an electric spark is introduced into the mercury vapour and ultra-violet radiation is produced. This activates the fluorescent material which glows with high illuminating power. Many coloured lights may thus be obtained which were hitherto unobtainable by incandescence, and a daylight effect can be achieved that is more stable than natural daylight, which varies with the time of day. A conspicuous feature of this fluorescent lighting is the absence of infra-red radiation which, on absorption by glass, results in the generation of heat. This form of lighting, therefore, is well adapted to rooms where temperature must be retained at low levels. Extensive research has been conducted in the production of artificial lightning to facilitate the study of insulating materials suitable for the protection of power lines exposed to the hazards of natural lightning.

A century ago the useful metals, excluding the noble metals, were iron, steel, copper, lead, tin, a few of their alloys, and a few other metals more rarely used. As a result of industrial research, today there are more than 5,000 alloys used in industry. The obvious result of the introduction of these has been the construction of new mechanisms not possible to conceive within the narrow limitations of choice offered the engineer of a hundred years ago. The average automobile, for example, has more than 80 different alloys in its construction. Metallurgical research is pressing further toward the production of alloys to meet specifications designed to meet individual needs.

One of the most expensive wastes in metal construction is caused by corrosion, so that it is natural to find much research is devoted to overcoming the disintegration of metal from this cause. Although aluminium has played an important part in protecting susceptible metals from corrosion, and research workers persist in the hope of utilizing magnesium, most of the recent development centres around the applications of stainless irons and steels. The German invention, the so-called "18 and 8" rustless iron, containing 18% chromium and 8% nickel, has had a phenomenal development. For many years stainless steel had been used for cutlery but owing to difficulties in fabrication the use of stainless iron and steel for structures had been limited, largely because of its tendency to corrode in the neighbourhood of welds. A new welding process has been discovered which does not affect the fabric of the steel or its non-corroding property, so that the past few years have shown great increases in the use of this inexpensive steel.

Much progress has also been made in the electro-plating of metals as a protection against corrosion. Silver, gold, and nickel have long been used for plating, but research has facilitated the use of other metals adapted to this process. During the past 15 years chromium plating has come into wide use. Anodic coatings for metals have also been developed. In this process the metal is hung at the anode of an electric circuit in a bath containing either chromic or sulphuric acid. This builds up a coating of the oxide of the metal which acts as a protection.

Research has been applied profitably to the adaptation of electrical processes to metallurgy. Numerous metals are refined by the electrolytic process. So great is the saving achieved that much spoil from old mine workings, once regarded as too low in metal content, may be worked economically by the new process.

One of the most recent products of industrial research is the art of producing objects from metal powders under hot or cold compression. In this way a number of adaptations of metals is made possible which cannot be obtained by any other method.

Although the Diesel engine was patented in 1892, its use was restricted to large engines. Intensive research has produced a lighter weight engine of great power which has led to a much wider adoption. The reduction in weight has permitted its use on railroads, in motor trucks and buses, and in tractors. Because of its operation upon a tax free fuel, its freedom from electrical ignition, and the great power derived from high compression, it is an advantageous field for further research.

Activity prevails among research workers in a multitude of other branches of engineering, notably in refrigeration, heating, welding, and allied industries. Notable results have been achieved in research directed toward the improvement of many instruments required to promote the rapid progress made in industrial processes and in transportation facilities. These are of such a divergent nature that a representative selection is well nigh impossible. In the development of safety devices in transportation alone, mention might be made of such features as the gyroscopic compass, position and direction finders operating with radio beacons, depth sounding, signals being delivered directly to the cab of a locomotive, and the collection of instruments which have been developed to facilitate the flying and landing of aeroplanes. This latter operation has now become almost automatic. The results of the past few years' experience have shown that the roots of industrial development are the research laboratories, and these roots have penetrated so deeply and widely into the rich soil of applied science that there is no possibility of suspending their growth.

RESEDACEAE, in botany, the mignonette family, dicotyledonous plants, mostly xerophytic herbs. There are six genera and about 70 species. *Reseda odorata* is the mignonette (q.v.); *R. lutea* is dyer's wood. (See WOOD.)

See F. Bolle, "Resedaceae," Engler and Prantl, *Die Natürlichen Pflanzenfamilien* 17b: 659-692, figs. 427-434 (1935).

RESENDE, ANDRÉ DE (1498-1573), the father of archaeology in Portugal, began life as a Dominican friar, but about 1540 passed over to the ranks of the secular clergy. He travelled in Spain, France and Belgium, where he corresponded with Erasmus and other learned men. He was also intimate with King John III. and his sons, and acted as tutor to the Infante D. Duarte. In Portuguese he wrote: (1) *História da antiguidade da cidade de Évora* (1553); (2) *Vida do Infante D. Duarte* (1780). His chief Latin work is the *De Antiquitatibus Lusitaniae* (Evora, 1593).

See the Life in Farinha's *Colecção das antiguidades de Évora* (1788).

RESENDE, GARCIA DE (1470-1536), Portuguese poet and editor, was born at Évora, and began to serve John II as a page at the age of ten, becoming his private secretary in 1491. He was present at his death at Alvor on Oct. 25, 1495. He continued to enjoy the same favour with King Manoel, whom he accompanied to Castile in 1498, and from whom he obtained a knighthood of the Order of Christ. In 1514 Resende went to Rome with Tristão da Cunha, as secretary and treasurer of the famous embassy sent by the king to offer the tribute of the East at the feet of Pope Leo X. In 1516 he was given the rank of a nobleman of the royal household, and became *escrivão de fazenda* to Prince John, afterwards King John III, from whom he received further pensions in 1525. Resende built a chapel in the monastery of Espinheiro near Évora, the pantheon of the Alentejo nobility, where he was buried. Resende collected the best current verse of the time in the *Cancioneiro Geral*, probably begun in 1483 though not printed until 1516.

The *Cancioneiro* is redeemed from complete insipidity by Resende, and his fine verses on the death of D. Inez de Castro inspired the great episode in the *Lusiads* of Luis de Camoens (q.v.). Resende is the compiler of a gossiping chronicle of his

patron John II, which, though plagiarized from the chronicle by Ruy de Fina, has a value of its own. Resende's *Miscellanea*, a rhymed commentary on the most notable events of his time, which is annexed to his *Chronicle*, is a document full of historical interest, and as a poem not without merit.

His *Condição* appeared in 1516, and was reprinted by Kausler at Stuttgart (3 vols., 1846-52). A new edition was published by the Hispanic Society of America in 1904. The editions of his *Chronicle* are those of 1545, 1554, 1560, 1607, 1622, 1752 and 1798. For a critical study of his work, see Antonio de Castillo, *Excerptos, seguidos de uma notícia sobre sua vida e obras, um juízo crítico, apreciação de belleza: e defeitos e estudo da lingua* (Paris, 1865). Also Anselmo Bramcamp, *As sepulchras do Espinho* (1901) *passim*, especially pp. 67-80, where the salient dates in Resende's life are set out from documents recently discovered; and Dr. Sousa Viterbo, *Dicionário dos Archteitos . . . Portuguezes*, II, 361-74.

RESERVE: see ARMY and the sections *Defence of FRANCE, GERMANY, UNITED STATES* and other countries.

RESERVES: see BANKING AND CREDIT.

RESERVES, NATURAL: see PHYSICAL RESOURCES.

RESERVOIRS. These may be divided into two classes, "impounding reservoirs" and "service reservoirs," the latter being concerned with the distribution of water (see WATER SUPPLY).

Impounding Reservoirs.—Owing to the fact that the flow of streams and rivers varies greatly throughout the year, it is necessary to provide works to store water if any substantial use is to be made of the annual discharge. Such works are known as impounding reservoirs, their function being to store water when the stream flow is ample for the purpose of augmenting the natural flow in dry weather.

The urgency for the construction of such reservoirs must have become apparent in very early times in countries where the climatic conditions were such that the streams ran dry for a portion of the year, and records exist of one being made in Ceylon as early as 504 B.C. Anciently reservoirs were formed by an embankment across the valley through which a stream flowed, and were sometimes of vast extent, the Padavi-Colan Tank in Ceylon, for instance, having an embankment 11 m long and, in parts, 70 ft. high.

Storage.—Having selected a catchment area capable of yielding sufficient water, the capacity of the reservoir has next to be determined. This will depend upon the incidence and intensity of the rainfall and the loss by evaporation and absorption, conditions which vary within wide limits. In countries subject to long periods of drought, the necessary capacity will be greater than in those enjoying a temperate climate, and in India, for instance, where the rain falls only during monsoon periods, two years' storage of the daily quantity may be necessary.

Few records exist of the flow of streams in the British Isles taken over a sufficiently lengthy period to be of service, and recourse has generally to be made to the annual rainfall records, from which the annual discharge of the stream is deduced. Long period rainfall gaugings show that the rainfall of the driest year is about two-thirds, the mean fall of the two driest years about three-quarters, and the rainfall of the three driest consecutive years about four-fifths, of the average annual rainfall. Notwithstanding the wide variation of climatic conditions, these proportions hold fairly well over a large portion of the land surface of the globe (see "The Variations of Rainfall," by A. R. Binnie, *Proc. Inst. C.E.*, vol. 109).

As storage increases in relation to the average flow of a stream, the maintainable yield increases in a decreasing ratio until a maximum is reached where there would be little advantage in further increase, and in the British Isles the economic limit is generally taken as that capacity which would be sufficient to equalize the flow of the three driest consecutive years.

The average annual rainfall of the three driest consecutive years, being approximately four-fifths of the average annual rainfall; and the average annual loss by evaporation and absorption being about 14 inches; the average annual discharge of the stream during the three driest consecutive years would be that due to $\frac{4}{5}$ average rainfall—14 inches running off the catchment area, which may be denoted by f . The formula known, from its author, as the Hawksley Formula gives the number of days

storage which should be provided to maintain this flow = $\frac{1000}{\sqrt{f}}$

In many cases it is not necessary to provide so large a storage, as some quantity may be required which is less than the average flow of the stream during the three driest consecutive years.

Fig. 1 gives the relation between the maintainable yield and the capacity to be provided for catchment areas in the British

FIG. 1

Isles having a mean annual rainfall varying from 100 to 30 in., and is due to the investigations of Dr. G. F. Deacon. The capacity of the reservoir in gal. per ac. of catchment area is shown on the base line, and the yield of the reservoir in gal. per ac. per diem is given by the length of the vertical line between that capacity and the curve of average rainfall, the yield in gal. per ac. per diem being read from the vertical scale at the left-hand side. The storage required for any particular average rainfall to balance the average stream discharge during different series of consecutive dry years, is given by the diagonal lines which intersect the curve of rainfall on the diagram.

The diagram gives the capacity above the lowest draw-off level of the reservoir, and as it is undesirable to abstract muddy water for supply, this level should be well above the bottom of the reservoir. The loss by evaporation from a water surface is greater than the loss on the catchment area, and in the British Isles the depth of the reservoir should be about 6 in. more than would be required to give the gross storage, whereas in tropical countries the allowance may be as much as 6 ft.

TYPES OF DAMS

Dams may be divided into two classes, masonry or embankments; and the selection of the particular type will depend upon the nature of the materials on which they will rest, and which are available for construction.

Where good sound rock exists at no great depth from the surface, a masonry dam is to be preferred, but where the rock can

only be reached at a considerable depth, the cost is prohibitive.

Masonry Dams.—Masonry dams should be arched in plan concave to the water face where the length of the dam is not too great, as such a form adds to the stability, and the pressure of the water tends to close temperature or contraction cracks at right angles to the axis of the dam. It is desirable to slope the foundations towards the water face, especially where the depth below the surface is moderate, as this reduces the tendency to slide on the foundations and the possibility of overturning due to the uplifting pressure of water penetrating between the masonry and the rock. The design should avoid the development of tension in the masonry, tending to rupture the dam on a horizontal plane; and the maximum pressure at any point in the masonry should be limited to 10–15 tons per sq.ft., depending on the materials used for construction and the nature of the underlying rock. Prof. Rankine pointed out the importance of avoiding tension, and evolved the theory on which most modern dams have been designed, viz.: that the resultant pressure due to the weight of the masonry and the water thrust must fall within the inner third of the dam if tension is to be avoided. Any fissure developing at the water face due to tension tends to increase owing to the water pressure, and may ultimately lead to the failure of the dam (see Prof. Unwin, *Proc. Inst. C.E.*, vol. 126, and E. P. Hill, vol. 129).

The masonry of a dam is not isotropic as horizontal planes of weakness, where new work is superimposed upon that which has set, are difficult to avoid. It is advisable therefore to step the masonry at the water face so as to avoid the construction of a horizontal joint between old and new work.

The arched form of dam is economical when the radius of curvature is comparatively small, as the sectional area can be decreased by designing the dam as a horizontal arch transmitting the water thrust to its abutments. For reasons of economy modifications of the simple type of masonry dam have been introduced; these dams are of ferro-concrete construction, the pressure of the water being transmitted to buttresses by means of steel reinforced slabs or arches.

Earth Embankments.—The profile of the embankment requires careful study of the materials of which it will be composed, and slips have frequently occurred, leading to the complete or partial failure of banks, due to lack of local study and the adoption of a design which was unstable. Light sandy soils will stand at a high angle of repose, but clays or plastic materials require flatter slopes, the inclination decreasing as the base of the embankment is approached. On fig. 2 the inner line profile would apply to good banking material, and the outer line to clay or plastic material.

FIG. 2

ment is approached. On fig. 2 the inner line profile would apply to good banking material, and the outer line to clay or plastic material.

Care must be exercised to prevent the saturation of the outer slope of the bank, and when possible it should be composed of freely draining material. When such materials are not available, the outer portion should rest on a layer of stone terminating in a stone toe, vertical drains of dry stone being carried up through the bank at intervals.

Cut-off Trench.—In order to prevent percolation below the bottom of the embankment, a trench is first excavated across the valley bottom, carried down—if possible—to an impermeable substratum and continued into the hillsides, so as to cut off any percolation below top water level. This is filled with impermeable material, preferably concrete, so as to form a barrier to percolation below the bank; and an impermeable core wall is brought up in continuity with this barrier to prevent percolation through the bank.

Core Walls.—Puddle is the material generally used in the British Isles to form the core wall, and reinforced concrete in America. Puddle is not an absolutely impermeable material, and the thickness of a puddle core wall must be much greater than that of a concrete core wall. The use of concrete core walls has been limited in the British Isles owing to the apprehension that such walls would crack under pressure due to unequal settlement of the embankment. That such fears are unfounded is proved by the numerous successful examples of such construction in America.

The very greatest care must be exercised in the construction of a puddle core wall to prevent the occurrence of any layer through which water could pass owing to the erosion which may take place, causing the formation of a cavity and the failure of the bank; whereas no erosion of the concrete would take place, and a crack would soon be sealed by earth carried in suspension by the water.

Tunnel Outlets.—It is necessary to divert the stream during construction, and for this purpose it is advisable to construct a tunnel round one end of the bank through which the stream may flow, and through which the supply pipe can ultimately be laid from the Valve Tower. A cheaper form of construction is to build a culvert under the bank, but many cases of whole or partial failure of such culverts have occurred due to the varying earth pressure. (See C. J. Wood, "Tunnel Outlets," *Proc. Inst. C.E.*, vol. 59.)

Flood Works.—When a reservoir formed by a masonry dam overflows, water passes harmlessly over the top of the masonry into the stream below. It is obvious, however, that water cannot be allowed to overflow an earth embankment, as the material would rapidly erode, leading to the failure of the bank. It is therefore necessary to allow for the escape of flood water in such a way that the water level can never rise to a height that would endanger the bank.

The usual flood escape is provided by a weir of such a length and placed at such a level below the top of the bank as will ensure that the water in the reservoir can never rise above it, the weir discharging into a masonry channel placed in the hillside at one end of the bank. Another and more economical escape consists of a vertical shaft communicating below with the tunnel through which the stream was diverted during construction and terminating above in a hell-mouthed opening, the periphery of which forms the overflow weir.

Flood Intensity.—The maximum intensity of the flood discharge over the weir will depend on the extent of the catchment area, the maximum intensity of rainfall during a period bearing relationship to that area, and many other factors, such as the inclination of the valley, the steepness of the slopes, the permeability of the surface, and the presence of lakes or obstructions which would delay the discharge. It is impossible to determine the exact effect of many of these factors, and therefore recourse must be made to actual records of the maximum discharge from catchments of different areas.

The main factor in determining the maximum intensity of a flood must obviously be the amount of rain which fell in a given period, a condition which varies so widely in different parts of the globe, that records of flood discharge in one country would not be applicable to another.

The curve on fig. 3 shows the relationship between rainfall and period, and is derived from the formula determined by Prof. Talbot as applicable to the Eastern United States for maximum rainfall during different periods. The small circles show actual observations made in the British Isles, from which it appears that Talbot's curve fits British conditions fairly well. This fact is of importance as indicating that records of floods in the Eastern

FIG. 3.—MAXIMUM RAINFALLS OF RARE INTENSITY

States are of assistance in arriving at the maximum intensity of discharge from different catchment areas in the British Isles. The larger the catchment, the smaller is the flood discharge per unit of area.

Unfortunately, the estimates of maximum flood discharges from small catchment areas, are scanty and not very reliable. Most reservoirs are placed at comparatively high altitudes, where the catchment area is small, in order to impound water free from pollution and to furnish water to the district of supply by gravity. Failures of such reservoirs, due to insufficient provision for the discharge of flood water, are not infrequent, and demand serious consideration owing to the consequent loss of life and property.

The formula $Q = 750/\sqrt{M}$, where Q denotes the maximum flood intensity in cu.ft. per sec. per sq.mi. and M the drainage area in sq.mi., agrees fairly well with the records of maximum flood intensity in Great Britain. (See also WATER SUPPLY; DAMS; CATCHMENT AREAS.) (W. J. E. B.)

RESHT, the capital of the province of Gilan in Iran, in 37° 17' N., and 49° 36' E., on the left bank of the Siah Rud which is a branch of the Safid Rud and flows into the *murdab* or lagoon of Pahlavi (Enzeli). Population (census of 1940) 121,625.

During the Bolshevik invasion in 1920 about 8,000 refugees left the town, but later returned; and a large part of the bazaar was burnt. The town is situated in low malarious ground and was originally buried in jungle, but the Russians during their occupation of the place in 1723-24, cleared most of the jungle and it is now surrounded by rice fields. The summer climate is damp, sultry and unhealthy, with an average minimum temperature of 84.5° F. in August and a rainfall of 32 to 59 inches. The houses are mostly of handsome, though soft, red brick, are red-tiled or thatched, and often raised from the ground, with broad verandahs and overhanging eaves.

Most of the streets are paved with cobble stones, an improvement which was begun in 1910. There are many caravanserais in the city.

Resht is the centre of important roads in Gilan. The metalled road from Tehran (226 mi. distant) via Kazvin to Pahlavi skirts the town on the east, upon which a regular motor transport service is in operation. There is a similar road to Pir i Bazar (4 mi. up the river of the same name which runs into the lagoon), whence there is a regular daily service of flat-bottomed sailing boats to Pahlavi. Launches also run between the bar at the mouth of the Pir i Bazar river and Pahlavi. A narrow gauge railway runs alongside the Resht-Pir i Bazar road. A good motor road also runs laterally from Kasma through Resht to Lahijan, Langarud and Rud-i-Sar on the Caspian sea, following in great part a raised causeway through rice fields, with innumerable wooden bridges over irrigation canals. Resht is a centre of the rice trade and of the activities of the silk industry of Gilan, but the principal centre of the latter is Lahijan. There is a town telephone service with trunk lines to Pahlavi, to Rud-i-Sar, to Pir i Bazar and to Tehran. The Imperial bank of Persia has a branch at Resht and the town is lit by electric light.

Resht suffered a good deal during World War I from the Russian army and, afterwards in 1918, when the Dunsterville force had to fight its way to Pahlavi, strongly opposed by Kuchak Khan.

RESIDENCE, in general, a place of abode. In law, it usually means continuance in a place. The ordinary meaning of the word has been defined as "the place where an individual eats, drinks and sleeps, or where his family or his servants eat, drink and sleep" (R. v. North Curry, 1825, 4 B. & C. 959). For certain purposes, however, a man may be said to have his residence not only where he sleeps, but also at his place of business. (See ABODE; DOMICILE.)

RESIDENT, a political agent or officer representing the Indian government in certain native states in India; he resides in the state and advises on all matters of government, legislative or executive. In certain other dependencies or protectorates of the British Empire the representative of the government is termed a resident or political agent, notably in Nepal, Aden, Sarawak, British North Borneo, etc. In general, where the state to which a resident is attached is not an independent one, he exercises consular and magisterial functions.

For "Resident" as the title of a diplomatic agent see DIPLOMACY.

RESINS. Prior to the introduction of synthetic resins, the term resin was applied exclusively to certain sticky substances which exude in the form of yellow or brown deposits from certain trees, particularly from the pine and the fir. As knowledge gradually accumulated concerning the nature of such natural resinous products as well as the means by which similar compositions could be made by known chemical reactions, a large and ever-increasing number of products have been included in the category of resins. At first these products of the laboratory were hesitatingly referred to as resinlike products, then as artificial resins and as resin substitutes and finally as synthetic resins. In almost every respect, the natural resin can be replaced by one of the synthetic varieties in many of the industrial applications, especially in the moulding and the coating industries. Through the study of chemical reactions which lead to resinification, a better insight was gained concerning the chemical transformation which takes place in the natural product with the result that, in certain instances, it became possible to combine chemically the natural and the synthetic product leading to the formation of a new material possessing unique properties.

At one time resins were recognized by certain well-known attributes, that is, by their transparency and amorphousness and by their brittleness and conchoidal fracture. Synthetic resins of all types are known, and certain of them fail to exhibit any of these characteristics. Some of the latter preparations are tough and colourless, whereas others are opaque and crystalline. There appears to be only one property which is common to both natural and synthetic resinous products—in one stage of their existence both products are plastic.

The distinction between resins and plastics is at best arbitrary since many of the later synthetic materials can be called both resins and plastics. Historically, it appears that the term resin was applied to those products which were primarily used as substitutes for the natural product entering into coating compositions, whereas the term plastic was used to designate those compositions which involved a moulding operation in their fabrication. It is generally recognized that resins, plastics, rubbers and fibres are part of one large group of chemical compounds, and by suitable transformations it is possible to change any one member of this group into another.

NATURAL RESINS

The resin formation in a tree occurs as a result of injury to the bark inflicted by wind, fire, lightning or other means. Initially this secretion is fluid in nature and appears in the form of an oleoresin or as a balsam. In contact with air certain of the more volatile components evaporate, and the residue oxidizes, polymerizes and gradually converts to a soft, resinous product which is readily soluble in appropriate media. As the natural resin gets older, it becomes more insoluble. When the resin flow from the tree is copious, some of the secretion passes into the ground, with the result that many of the fossil resins are found as buried deposits. Even in the case of the recent fossil resins, the chemical reaction leading to resinification may have proceeded for thousands of years. For example, the kauri pines are known to attain an average age of 1,000 years; and since resin can now be found in areas where the original forest has wholly disappeared, it is obvious that the resin must be extremely old. This resin is still soluble. The fossil resin, amber, is of a less soluble type. The very existence of this resin indicates that the process and time of polymerization from the oleoresin to resin, to recent fossil resin,

to fossil resins must, in the case of amber, be reckoned in geological periods.

Resinous deposits are found in many parts of the world, and many varieties derive their names from the locality where they are collected. Not only are these products derived from many lands, but they have been known and used technically for long periods of time. Certain tree emanations were utilized by the Chinese and the Japanese in their preparation of oriental lacquers. There is reason to believe that the Incas and the Egyptians used varnishlike materials. The Carthaginians, Phoenicians and Greeks were acquainted with resinous products, and the association between resins and varnishes can be seen in the derivation of the word varnish. This term appears to originate from Berenice, queen of Cyrene, the name the Greeks applied to amber. The term Berenice became corrupted gradually to Pheronice and then Verenice and Vernis.

Amber is not used in the preparation of varnishes but is mainly employed in the fabrication of beads and in decorative wear. In certain respects amber can be handled in very much the same manner as that employed in the fabrication of cast plastics.

Any mucilaginous exudation of a tree is considered a gum. Shellac is a distinctive product inasmuch as it is an insect secretion. True gums, as distinct from varnish gums, are soluble in water; for example, gum arabic which is used in the manufacture of adhesives. The true gums are related to sugars and carbohydrates. These products are soluble in water and insoluble in organic liquids and on heating decompose without fusion. They differ from glues in that they are soluble in cold water. Varnish gums, on the other hand, are resinous materials related to terpenes and essential oils. They are soluble in oils and organic liquids but are insoluble in water. On heating they generally melt and decompose and become more readily soluble. Although the tendency has been to decry the use of the word gum for varnish resins, the term is too well established to be eradicated. Moreover, there are certain natural products which take on the properties of both gums and varnish resins. From Indian frankincense or olibanum, a water-soluble gum has been isolated as well as terpenes and a resinlike product.

Natural varnish resins, as has been noted, can be recognized by their transparency and translucency, by their brittleness and conchoidal fracture and by their brown or yellow coloration. As a rule they possess no taste or smell in the solid state. On heating they melt and often give off a distinctive aromatic odour; on burning they yield a smoky flame. Certain of these gums will dissolve directly in various organic liquids such as alcohol or turpentine. In dispersing the more insoluble resins in oils, it is necessary to preheat the resin—a process referred to as running or sweating. No generalization can be made concerning the chemical changes which occur during the running operation, but it involves complex and deep-seated chemical rearrangements such as cracking, decarboxylation and dehydration. All of these changes are accompanied by a loss in weight; it is by such heat treatment that the resins become more readily dispersible in oil.

Solubility and hardness are the chief criteria used technically in classifying resins, and on the basis of solubility resins can be divided into the spirit-soluble and oil-soluble types. Spirit-soluble means what the word implies, solubility in commercial spirit or ethyl alcohol. Many new powerful organic solvents have been developed for the preparation of cellulose lacquers, and a number of these liquids can likewise be employed in the preparation of solutions of natural resins. Congo is substantially insoluble in all liquids. Rosin and Mastic are soluble in alcohols but are insoluble in hydrocarbons. Dammar is soluble in hydrocarbons but only slightly in alcohols. Avicenna and sandarac are soluble in alcohols but are insoluble in hydrocarbons. Shellac and copal are soluble in alcohols and in hydrocarbons.

Spirit-Soluble Resins.—The term *spirit-soluble* is applied to those resins which are soluble in ethyl alcohol and have found their chief use in the preparation of lacquers and varnishes. The most important of these are the resins of the genus *Acacia*, which have been extensively used in the preparation of varnishes. The resin of the *Acacia* is a lac which has been allowed to fall on a flat surface. Lac is one of the widely used resins in industry. It is also used in electric insula-

oleoresins are considered to be solutions of resins in essential oils. However, it is difficult to draw a rigid distinction between balsams and oleoresins, although the latter are usually considered to be slightly more fluid. Canada balsam, which is used in cementing lenses, is not a true balsam in that it does not contain benzoic acid or its ester, but is really an oleoresin derived from *Abies canadensis*. Certain of the true balsams are the balsam of Tolu, the balsam of Peru, as well as the Sumatra and Siam benzoin and storax. The storax balsam is of particular interest from the standpoint of synthetic resins in that it was from this material that M. Bonaer in 1831 first isolated styrene, and doubtless this product arose through decarboxylation under heat of the cinnamic acid present in the balsam. Another variety of balsam is derived from the grass trees of Australia, and these products are referred to as the Xanthorrhoea balsams. The most important varieties are the yellow and red types, often referred to as accroids gum. This resin contains phenolic bodies which appear to possess some medicinal values, particularly for treating infections of the mucous membranes.

As stated above, oleoresins are solutions of resins dispersed in essential oils; various of these oleoresins are known as turpentine. Venice turpentine is a pale green, viscous liquid which is collected from the larch (*Pinus larix*, *Larix decidua*). A liquid of lemonlike odour known as Strasbourg turpentine is derived from the *Pinus picea*, whereas Bordeaux turpentine is an oleoresin derived from the *Pinus maritima* or pinaster. The chief American varieties yielding oil of turpentine are the loblolly pine, *Pinus taeda*, and the slash pine, *Pinus caribaea*. On evaporation of the oleoresin a solid resin results, together with a volatile component or spirit of turpentine. The residue from distilling Bordeaux turpentine is known as Burgundy pitch and is used in medicinal plasters.

Mastic is a soft resin melting at about 105° C. and is derived from the tree of the *Pistacia* genus which grows in the islands of the Greek archipelago. When dissolved in turpentine, it is used as a varnish for the protection of paintings; and when dispersed in bodied linseed oil, it is known as megilp and is used as a colour vehicle. Dragon's blood is a black-brown resin in bulk, but in thin films it is transparent and of a deep crimson-red colour. The resin is found on the fruits of the ratan palm growing in the East Indies. It is soluble in alcohol and benzene, but not in ether or turpentine. The resin has been used as a varnish by Italian violin makers and as a dye to colour spirit varnishes a deep red. Another resin used as a colour vehicle and in medicine is gamboge.

Dammar is one of the harder resins and is usually secured in the form of clear, pale-yellow beads, melting at about 140° C. Various other coloured varieties are obtained from the *Dammara orientalis*, which is indigenous to Malaya and the East Indies. The resin is insoluble in alcohol but dissolves in both aliphatic and aromatic hydrocarbons. Excellent varnishes can be made from these solutions, and the resulting films have a light colour and a good lustre. The resin is also readily soluble in oils without preliminary thermal processing. This resin in combination with nitrocellulose enabled the formulation of rapid-drying lacquers.

From the cypress pine, *Callistris*, which grows in Australia, North Africa and North America, one can obtain the hard resin called sandarac which is soluble in alcohol as well as in the more-powerful lacquer solvents. The resin melts at 150° C. and is used as a spirit varnish for coating paper, leather and metal. Although the initial film is somewhat brittle, it can be readily modified to yield elastic films by the addition of elemi.

Shellac has been considered a zochemical substance, inasmuch as it is a secretion of an insect known as *Laccifer lacca*. The word lac, appears to be derived from *laksa*, an early Sanskrit word meaning 100,000. The term shellac has been used incorrectly to cover generically all of the lac products. Insects growing on certain of the trees of the genus *Acacia* produce a scaly substance known as stick-lac. This material is ground, washed and filtered hot, the filtrate passing onto water-cooled drums from which it is removed in the familiar flake-like form. The button lac is a lac which has been allowed to fall on a flat surface. Lac is one of the widely used resins in industry. It is also used in electric insula-

tion as a coating for wood and metal and as a binding agent for moulding composition. Certain varieties are incorporated into sealing waxes. The bulk of the shellac manufactured bears the mark T.N.

Chemically, shellac consists of a mixture of polyhydroxy acids. Two varieties have been isolated, one a hard lac and one a softer material which appears to act as a plasticizer for the harder component. The softer portion consists primarily of uncombined acids, whereas the harder material consists of polyesters. A major portion of the hard lac was found to be a mono-bis ester which could be made to undergo hydrolytic fission to aleuritic acid and laccolic lactone. Other acids which have been isolated from shellac are a tetrahydroxy acid known as kerric acid, as well as shellolic acid, together with a natural yellow dyestuff known as erythrolaccin. Aleuritic acid is considered to be 9,10,16-hexadecatrienoic acid ($\text{HO}-(\text{CH}_2)_9-(\text{CH}_2)_2-(\text{CHOH})_2-(\text{CH}_2)_2-\text{COOH}$). Although the solubility of shellac is usually associated with alcohol, it is also dispersible in aqueous solutions. There appears to be some indication that on long standing alcohol may react with shellac. A white variety can be made by a bleaching process from which colourless, transparent lacquers can be made.

Oil-Soluble Resins.—Upon distillation of the oleoresin from the longleaf pine two materials are obtained: one a volatile component or spirit of turpentine and the other a nonvolatile, resinous residue or rosin. The word rosin is used for this product rather than resin because the latter is a term used generically to cover all of the compounds of this type. Depending on the source of the oil of turpentine, it is possible to have either gum turpentine and gum rosin or wood turpentine and wood rosin; the former variety originates from the turpentine which is secured by tapping the trees. By solvent extraction of the stumps, wood rosin is obtained, and this is generally of a darker colour. Various designations are employed to distinguish the colour of the product. The colour of French rosin is designated by the letter A, and the greater the number of As used the paler the grade. The U.S. designation is more arbitrary, and the better classes are known as WW (water-white) and WG (window glass). Rosin is a brittle resin which powders readily and becomes sticky when warm. Its specific gravity is about 1.070 to 1.080, and it dissolves in the usual organic liquids. Rosin is also known by the name of colophony or colophonium (from the Greek *Kolophonios*). The suggestion that the term was derived from two Greek words meaning sound-glue because of its use for treating violin bows does not appear satisfactory.

At one time much of the rosin was used untreated, but the trend is to subject it to chemical processing before it is offered for sale. The chief constituent of rosin is an acid known as abietic acid, and many of the uses of rosin are dependent upon its acidic properties. Combined with alkalis or with metallic oxides, soaps are obtained. The sodium soap is water dispersible and is employed in sizing paper. Sodium abietate is mixed with other alkali soaps in the manufacture of laundry soap. The lime and zinc salts find use as so-called gloss oils in the paint industry, whereas the metallic soaps derived from lead, cobalt and manganese are used as driers in paints and varnishes. When rosin is esterified with glycerol (glycerine), the resulting product is known as ester gum. Somewhat harder esterification products are made through a conjoint ester of rosin with glycerol and with phthalic anhydride. Partial decarboxylation of acid occurs when rosin is heated to elevated temperatures; such products are known as rosin oils.

The acids isolated from rosin include abietic acid,

pinic acid,

and laevopinic acid, CH_3

It will be noted that certain of these acids appear to possess a system of conjugated double bonds which may account for the ease with which rosin oxidizes when it is exposed to air. By chemically combining rosin with hydrogen it is possible to obtain a product which exhibits greater stability and is less subject to discoloration on storage. The abietic acid in rosin can be made to undergo hydrogen disproportionation leading to the so-called dehydrogenated rosin. This type of chemically modified rosin, as the sodium soap, was used extensively during World War II as the emulsifying agent in the preparation of synthetic rubber. The properties of the modified rosin were such that it could be allowed to remain in the coagulated rubber. Hydrogenation and disproportionation both cause rosin to crystallize more readily, and consequently the hydrogenation is carried only to the point where satisfactory stability can be secured without crystallization. By combining rosin chemically with certain unsaturated types of dibasic acids, such as maleic and fumaric acid, it is possible to destroy the unsaturation without inducing crystallization. It is probable that the character of the varnish which can be made from China wood oil, and rosin derivative may reside in the chemical combination that takes place between the unsaturated components of both products.

The copals form an important group of varnish resins. The word copal appears to have been derived from the Spanish or Mexican word *copalli*—incense. Various types of products are known—the recent varieties as well as the fossil types. Soft Manila copal is readily soluble in organic solvent liquids and in oils or, as in the case of the pontianak variety, it requires running before it can be dispersed in oil. There are several varieties which are employed in the varnish trade: kauri copal, melting at about 150° C., is derived from the New Zealand pine; Congo copal originates in the Belgian Congo; while Zanzibar copal is dug from the mainland opposite the island of Zanzibar. Some of the South American copals derived from Brazil and Colombia have attracted some attention. Copal has been esterified with glycerol in a manner similar to that employed in making ester gum. Because of the high melting point of the copal gum, it is necessary to conduct this thermal decomposition to a point much further than is customarily employed when the resin is to be dissolved in oil, and temperatures as high as 330° C.–340° C. are employed. Two acids have been isolated from Congo copal; one is the dibasic congoic acid ($\text{C}_{28}\text{H}_{48}(\text{COOH})_2$), and the other is the monobasic congoic acid ($\text{C}_{27}\text{H}_{48}(\text{OH})(\text{COOH})$).

Amber, the hardest natural resin known, finds little use in the varnish industry because of its lack of solubility. When it is incorporated in oil, so much discoloration takes place during the running operation that the resulting varnish is of a poor colour. The resin is found in the so-called blue earth, in east Prussia in the Baltic region. The fact that it is derived from a variety of *Pinus* indicates that over a sufficiently long period of time under

appropriate conditions an oleoresin can be converted into a heat-insoluble product.

Oriental lacquers are a distinct product derived from the *Rhus vernicifera*, a tree which is indigenous to China. The process was introduced into Japan and remained secret for centuries. A milky emulsion secured from the tree is concentrated by evaporation to a viscous liquid which resembles a bodied oil. When this is applied as a thin film, it hardens in about a day to form a tough skin. The composition is peculiar in that it will dry only in the dark and in a moist atmosphere; exposed to light and warmth, the varnish remains tacky. The varnish contains a skin irritant, and this material may be the urushiol which is similar to a product isolated from the *Rhus toxicodendron* or poison ivy, which is common in the United States.

Another product containing phenolic bodies is derived from the nuts of the cashew tree (*Anacardium occidentale*); the oil known as the cashew-shell-nut oil possesses materials which lead to vesicant action, but by appropriate chemical treatment the irritant is destroyed. This product has found some commercial importance in the United States.

SYNTHETIC RESINS

Synthetic resins possess most of the physical characteristics of natural resins and in addition have many unique properties of their own. Chemically there is a certain degree of resemblance between the synthetic resins of phenol-formaldehyde and the natural phenolic resins found in oriental lacquer and in acroides gum. Moreover, one can trace a certain amount of resemblance between the polyester resins known as alkyds and the polyesters found in shellac. Although it has usually been considered that the synthetic resins possess the unique characteristic of becoming insoluble and infusible on heat treatment, it is known that shellac will become insoluble on prolonged heating, and the same phenomenon has been observed with certain of the other gums. The synthetic resins are of industrial interest not only as substitutes for natural resins in the coating industry but also because they find extensive use as adhesives, textile impregnants, binders, as agents for removing ions from water solutions and as binders in the plastics moulding industry (see PLASTICS).

Thermoplastic and Thermosetting Resins.—Physically it is possible to classify synthetic resins according to their solubility. There are those resins which remain permanently soluble and those which are initially soluble but become insoluble and infusible under the action of heat. The first type is known as the thermoplastic type of synthetic resin, whereas the latter is known variously as heat hardenable, thermosetting or thermocuring resins.

Linear and Three-dimensional Resins.—The permanently soluble or thermoplastic resins consist of molecules which are more or less linear in form. During solution in an organic medium, the solvent penetrates between the threadlike molecule; irrespective of the size of the resin molecule, solution will eventually occur. Under the influence of heat the threadlike molecules can be forced to move, and on cooling the impressed form is retained. On the other hand, the thermosetting resins consist of resinous molecules which are tied together three-dimensionally into a network pattern. In the initial stages where the network is small, solvent can readily penetrate the interstices of the network, but after chemical combination has taken place and a large three-dimensional network is formed, the resin becomes insoluble. Since the network is tied together rigidly, the resulting molecular structure is infusible.

Condensation and Polymerization Resins.—Two main classes may be distinguished under chemical classification: first, the condensation resin, such as the phenol-formaldehyde or melamine-formaldehyde type, in which the molecules unite with the elimination of water; and second, the polymerization resin, in which chemical reaction takes place through loss of unsaturation, without the evolution of any low-molecular-weight material.

Coating Resins: 1. Phenol-Formaldehyde Resins.—The chemical combination of phenols with aldehydes was noted by many investigators in the 19th century. Among the organic chemists who had studied the reaction were C. F. Gerhardt (1853), Adolf

von Baeyer (1872) and A. Michael (1883), but it was only after the advent of cheap formaldehyde in 1891 that a more extensive investigation was made toward the commercial utilization of this resin. Various investigations were made by W. Kleeberg, by A. Smith and by A. Luff, and certain of the methods employed resembled the technology which had proved successful with thermoplastic nitrocellulose plastics but which failed when such procedures were extended to thermosetting compositions. The first successful work in this field was carried out by L. H. Baekeland. Through a study of the various stages of resinification and through the utilization of a so-called bakelizer, he was able to mould many products, and in 1910 he organized the General Bakelite company. Much of the plastic entered into electrical goods. Meanwhile, the possibility of employing this condensation product to replace shellac in phonograph records was considered by J. W. Aylsworth of East Orange, N.J. On the basis of his development work, the Condensate Company of America was established at about the same time. Still another concern for the manufacture of phenolic resins was started by the Redmanol Chemical Products company, based on the studies of L. V. Redman. After much patent litigation these various companies pooled their resources.

In spite of the marked commercial success of these resins in moulding, in casting and in laminating, they were not suitable for coating compositions. While it was possible to make a phenolic varnish for laminating purposes, this varnish could be dissolved only in alcohol and could not be dispersed in cheap solvents or in drying oils. The first successful attempt to use phenol-formaldehyde resins directly as substitutes for natural resins in coating composition was the result of the work of Dr. K. Albert of Germany. He found that by a preliminary heating or fluxing of the phenol-formaldehyde resin with rosin or colophony, it was possible to disperse the resulting mixture in drying oils. These products, when dispersed in China wood oil, possessed rapid drying characteristics and formed films possessing good durability.

In 1928 the first so-called oil-soluble phenolic resin appeared on the market. Through the use of appropriately substituted phenols and the combining of such substituted phenols with formaldehyde, it was possible to obtain a resin which was directly soluble in oil without preliminary fluxing with rosin. These oil-soluble phenolic resins found wide acceptance in the varnish field. Among the phenols useful for such purposes are phenyl, phenol I, tertiary butylphenol II and cyclohexylphenol III, as well as certain of the

I

II

III

tar acids which boil in the xylene range. The resins are incorporated into the oil by adding resin in increments at a rate at which frothing can be controlled. After addition of the resin the temperature is raised until satisfactory increase in viscosity occurs. The European procedure favours the addition of the resin to the pretreated oil, and, while it appears to yield lighter coloured and less viscous products, the resulting films appear to be less resistant chemically. Other combinations are known, certain of which consist in substituting an alkyd resin for a part of the drying oil. Durable finishes have been made from alkyd-phenol-formaldehyde oil combinations.

2. Alkyd Resins.—These resins are reaction products of polyhydric alcohols and polybasic acids, and various modifications can be made by adding monohydric alcohols or monobasic acids to the polyester composition. The derivation of the term alkyd becomes apparent when it is pointed out that the "cid" from acid was changed to "kyd" for the sake of euphony. J. J. Berzelius

prepared glycerol tartrate in 1847; J. M. van Bemmelen prepared a resin by reacting succinic acid with glycerol in 1856; M. P. E. Berthelot esterified glycerol and sebacic acid in 1854; while M. A. von Lourenço prepared a resin from glycerol and citric acid in 1865. The most important dibasic acid employed in the manufacture of alkyd resins is phthalic acid. The phthalic acid (or phthalic anhydride) is obtained readily by the catalytic oxidation of naphthalene, and once this synthesis was properly worked out a ready source of this valuable commodity was available at a reasonable price. While the reaction product of glycerol and phthalic anhydride is of limited utility by itself, it is upon this structural vertebra that such ingredients as natural resin acids as well as drying and nondrying varieties of vegetable fatty-oil acids can be hung. Other dibasic acids are used where specialized properties are required. Maleic acid is obtained by the vapour-phase oxidation of benzene, while its geometrical isomer, fumaric acid, is obtained either by rearrangement of the maleic acid or by fermentation processes. Succinic acid can be prepared by the reduction of maleic acid. Sebacic acid and azelaic acids are incorporated into alkyd resins where exceptional flexibility is required, and these acids are manufactured commercially by treatment of castor oil or cottonseed oil, respectively, with caustic at elevated temperatures. Adipic acid is also available by the oxidation of cyclohexanol, which in turn can be derived from phenol. Glycerol is by far the most important polyhydric alcohol used, but ethylene glycol, diethylene glycol and pentaerythritol are used for merits of their own.

The drying-type alkyd resins first came into commercial prominence when it was demonstrated by R. H. Kienle that it was possible to form a new type of product by recombining the component parts of a drying oil, that is, the glycerol and the drying-oil acid in the presence of a saturated dibasic acid such as phthalic. Under these conditions, the cocondensation of glycerol, phthalic acid (as anhydride) and a drying-oil acid yielded a high-molecular-weight resinous condensation product in which the unsaturation of the drying-oil acid was substantially unimpaired. The result was that the resin would dry in a manner similar to the natural drying oil. Such resins in organic liquids yield solutions which resemble varnish and can be used as such. Since the resins could be dispersed in relatively cheap organic liquids, these varnish solutions found wide acceptance in coating various metals, as priming paints and as enamels. They are used to finish transportation equipment such as automobiles, streetcars and railway coaches and, because of their good chemical resistance, find acceptance as enamels for coating refrigerators and washing machines. Similar resin solutions are used in ornamental hardware, to coat metal furniture, metal signs and farm equipment, and, because of good heat resistance, these resins are employed to cover radiators, smokestacks and light reflectors. They find wide acceptance as architectural enamels, traffic paints and as printing-ink ingredients.

These resins are often used alone, but they show excellent compatibility characteristics with a wide variety of other film-forming agents such as nitrocellulose, natural resins, phenolic resins and urea and melamine-formaldehyde resins. With nitrocellulose it is possible to secure films possessing toughness, hardness and durability, as well as good gloss. It was this combination with nitrocellulose and alkyd resins which initially permitted the formulation of automotive finishes possessing an enamel-like quality and having excellent outdoor durability. When these resins are modified with natural resins, the melting point and hardness are increased; since such compositions release solvent very readily, they are used as rubbing and sanding vehicles. When mixed with urea-formaldehyde and melamine-formaldehyde condensation products, the alkyd resin becomes harder and more mar-resistant.

3. Polyester Resins.—While closely related to alkyd resins, the polyester materials differ from the conventional alkyd resins in that the cure is associated with a low-molecular-weight unsaturated organic liquid. The polyester resins, or anhydrous thermo-setting resins, usually comprise an unsaturated alkyd resin prepared from a polyhydric alcohol with an unsaturated acid such as maleic or fumaric acid. This alkyd resin is then dispersed in an

organic liquid such as monomeric styrene or with diallyl phthalate. This solution, appropriately stabilized for shipping, is treated with a peroxide catalyst just before use. The catalyzed resinous material is then employed in saturating various fibrous materials such as fabric or glass fibre. The cured composite structure of resin and glass fibre found use in such widely differing applications as plastic armour, trays, radar housings, luggage and lightweight boats.

4. Urea-Formaldehyde Resins.—The chemical condensation of urea and formaldehyde yields resins which are of great value both in the moulding and in the coating industry. The resins are characterized by extremely light colour, and products fabricated from such materials can be made into mouldings which are colourless. The fundamental chemical investigations of Hanns John laid the foundation for the use of this resin in the plastics industry; but in so far as coating resins are concerned, it was the observation of Kurt Ripper that proved most valuable. He found that under suitable conditions the water-soluble condensation product of urea and formaldehyde could be dispersed in organic liquids. To make the resin soluble in varnish solvents for coating use, it was first necessary to conduct the condensation of urea and formaldehyde in a solvent such as alcohol and then to remove the water of condensation as an azeotrope with the alcohol. The resin thus formed in alcoholic solution could then be diluted with aromatic solvents.

By themselves, films and coatings of the unmodified urea resins are hard and mar-proof and possess good colour and gloss but lack distensibility. From the standpoint of their use in enamels the resins are neutral, and consequently any type of pigment can be admixed with them. When these urea resins are blended with alkyd resins, they become flexible and adhere to metal surfaces. This combination of urea-formaldehyde resins and alkyd resins is in many ways a unique combination whereby the urea resins improve certain of the deficiencies of the alkyd resins such as increasing hardness and eliminating the tendency of the oil-modified alkyd resins to wrinkle on rapid drying. The urea-formaldehyde resins under the influence of heat contribute hardness, colour and gloss to the cured film, while the alkyd resins produce flexibility, drying ability and adhesion to metal surfaces.

5. Melamine-Formaldehyde Resins.—Many of the excellent characteristics exhibited by the urea-formaldehyde resins in coatings are also shown by the melamine-formaldehyde resins. Melamine, or polymerized (trimerized) cyanamide, is a heterocyclic compound which reacts with and cures rapidly in combination with formaldehyde. Unlike urea, which is low melting and soluble in water, melamine possesses a high melting point (354° C.) and dissolves very slightly in water. It is characterized by an exceptionally stable ring system of alternate carbon and nitrogen atoms—a stability which is reflected in the resins made from it. The melamine and formaldehyde resin can be dispersed in organic solvents by procedures similar to those employed for the urea-formaldehyde condensation product. When used in admixture with alkyd resins a much faster heat cure can be secured than when urea-formaldehyde is used. The outstanding characteristics which urea resins supply to films are further enhanced with melamine resins; these are superior in resistance to various chemical reagents, outdoor durability and colour retention on exposure to both heat and light. These properties, in addition to porcelain-like appearance and resistance to abrasion, enabled such finishes to enter into automotive coatings and industrial finishes on a large scale.

6. Coumarone-Indene Resins.—From the light oils present in the distillation of coal tar, it is possible to secure a fraction rich in indene, coumarone and related isomers. This mixture can be polymerized by means of sulphuric acid into resins of soft or hard consistency. These synthetic resins are one of the oldest-known synthetic products and have been available from the time of the initial investigations of G. Kraemer and A. Spilker in 1890. The resins exhibit good compatibility characteristics with a wide variety of other polymeric products, both synthetic and natural, and have been used in coating of concrete, in the manufacture of antifouling ship-bottom paints, as additives to paraffin

wax, in admixture with bitumens and as compounding agents in butadiene-styrene synthetic rubber.

7. *Silicones*.—The silicone resins are based on the silicon-oxygen skeleton rather than upon the carbon-oxygen chains or upon the carbon chain found in the conventional resins. This siloxane linkage, as the silicon-oxygen combination is called, introduces a degree of resistance to heat that is not found in those chains possessing carbon atoms exclusively. Naturally, those same reagents which can break the silicon-oxygen bridge in silicate minerals are also instrumental in causing the silicone resins to undergo cleavage; both hydrofluoric acid and strong caustic will cleave the siloxane chain in the silicone resins. Through the proper choice of ingredients, groupings can be introduced into the molecular structure whereby growth may be made to occur essentially linearly as, for example, through the introduction of saturated dialkyl-siloxy groups, or three-dimensionally through the utilization of the monoalkyl-siloxy groupings.

Various silicones can be made by changing the nature of the alkyl group, but most of the commercial production is restricted to the methyl silicones. Various polymeric structures have been made, certain of which are viscous liquids, others resinous; and even rubbery products have been produced. The liquids have found use as hydraulic oils and as instrument and transformer oils. Some of the higher-molecular-weight materials have found further application as varnishes as well as in high-temperature-resisting paints and enamels and as coatings for electrical insulation. When applied to the surfaces of glass or ceramics and baked, the silicones yield surfaces which are water repellent.

Resin Adhesives: 1. Plywood Adhesives.—Prior to the introduction of synthetic resins for plywood construction, laminated wood was susceptible to deterioration by water and high humidity. The natural protein products such as albumin and casein could not be rendered insoluble to the same extent as later became possible with various condensation products such as phenol-formaldehyde, urea-formaldehyde and melamine-formaldehyde resins. The new resin adhesives permit the construction of plywood in which the glue line is strong, resistant to water and immune to attack by the action of fungi, moulds and vermin. Such plywood can be used not only for architectural and automotive purposes but also for aeronautical and marine construction. Phenolic-resin adhesives became commercially available about 1935, while the urea condensation products were introduced about two years later.

Two types of synthetic glues are manufactured—cold-setting and hot-setting. Certain of the resins are supplied in powder form which requires solution prior to use, whereas other types are already dispersed in a liquid medium. Extenders such as cereal flour and wheat flour are sometimes employed where maximum strength and waterproofness are not essential. Phenolic resins yield an especially durable bond, but the resin is coloured, and the colour may bleed through thin veneers. Such colour is also a disadvantage where the glued edges are exposed. The urea resin is characterized by a rapid cure at low temperature and is widely employed in the preparation of cold-setting adhesives. The urea resin, moreover, is colourless and will not change the colour of the wood. Melamine resins likewise possess excellent colour characteristics, and in addition the glue line formed from this resin is resistant to cold as well as to boiling water.

Keeping pace with the development of new adhesives were new fabricating and moulding techniques which allowed the construction of complicated shapes particularly necessary in aeronautics and in boat construction. Flat sheets can be "post-formed" into simple curves, but for construction of compound curved surfaces a moulding procedure is preferred. This is accomplished by applying the glue to the veneers and allowing them to dry in order to permit easy handling. A mould is constructed with the exact contours needed in the finished assembly, and the coated wood veneers are placed in the mould and fastened by staples. The laminates are enclosed in a rubber bag which is evacuated in order to keep the veneers rigidly in place, and the assembly is placed in an autoclave and heated in order to render the resin insoluble and infusible. Such procedures enabled rapid construc-

tion of large aircraft parts, pontoons and motor torpedo boats.

2. *Wood Impregnation*.—Wood which has been subjected to reduced atmospheric pressure to remove occluded air can be impregnated with various resin solutions dissolved in water or in alcohol. After drying, the temperature is raised, whereupon curling of the resin occurs in the interior of the wood, rendering it harder, stronger and more resistant to water and water vapour. Through the addition of appropriate accelerators prior to impregnation the cure can be effected at a lower temperature with less damage to the structure of the wood. Phenol-formaldehyde, urea-formaldehyde and a mixture of the two resins have been employed for this purpose.

3. *Other Adhesive Applications*.—Many other resinous and rubbery compositions, dispersed in water or dissolved in organic liquids, are used to bind metals, plastics, glass, rubber, paper, brickwork, leather, fabrics and cork. Others are used in the manufacture of shoes, gaskets, furniture construction, lighting assemblies, sound insulation and upholstery. Certain of these adhesives have natural or synthetic rubber as a base, whereas others involve the use of synthetic thermoplastic and thermosetting resins. During World War II the reinforcement of starch by urea-resin adhesives in paperboard manufacture allowed the fabrication of paper containers which had a high resistance to water.

Resins for Textile Applications: 1. Continuous Coating.—One of the methods of separating electrical conductors is by means of a covering of cotton or silk, and so long as anhydrous conditions exist such insulation is satisfactory. In a humid atmosphere, the textile absorbs water, and its insulating efficiency is markedly decreased. To overcome this disadvantage, the dried fabric is treated with a varnish subsequently cured, thereby sealing the fabric. The varnish is selected in order that the water vapour transmission through the film of resin will be as small as possible. Among the resins which have been employed, the phenolic resins are the best known, although almost every type of natural and synthetic resin has been tested at some time or another for this type of insulating varnish.

2. *Impregnation of Fabrics*.—Resins are applied to fabrics for purposes other than to produce insulation; for instance, to improve the finish of cotton and rayon and to render them non-shrinking and crushproof. Resins have also been employed to bind pigments to the fabric, to minimize bleeding and crocking of dyes and as mordants for dyeing cellulosic fibres with wool dyes (animalized cellulose). Since no resin discoloration can be tolerated in uses of this type, the thermosetting resins which have enjoyed widest acceptance in this field are the urea-formaldehyde condensation products. In numerous applications, superior results can be secured only with the melamine-formaldehyde resins. Among the more notable achievements of the latter resin, the following may be mentioned: shrinkage control of cotton and wool; improvement in the crease resistance of cotton and rayon; production of durable glazes on chintz; preparation of binders to prevent thread slippage; and minimizing of gas fading of acetate colours. Many of these effects are achieved by treating textiles with low-molecular-weight water-soluble condensation products and then causing resin formation to occur on the fabric.

Quite different effects are secured by using high-molecular-weight water-insoluble thermoplastic resins which are dispersed in water. Such resins render the fabric stiff, crisp and full, and when properly formulated such properties are not destroyed by the laundering operation. Other thermoplastic resins impart good draping characteristics and improve the abrasion resistance of the textile, whereas still others are employed for upholstery finishing, raincoats, shower curtains and other waterproofing applications.

Resins Possessing Ionic Charges: 1. Ion-Exchange Resins.—By the introduction of strong acid groupings such as carboxyl and sulphonic acid into a three-dimensional polymer, high-molecular-weight resins can be made up where the resin is ionic in character and where the ion is chemically bound in the resin molecule. These ionic resins in the form of sodium salt can be used as a means of softening water whereby the calcium ions of the hard water are replaced by the sodium ions from the resin. In this respect the synthetic ion-exchange resins, generally known

as cation resins, behave like the natural zeolites; and, like the zeolites, the resins when used under such conditions do not change the amount of dissolved salt in the water.

Condensation products can also be prepared synthetically where basic groupings such as amino- and guanido- are bound in the resin molecule, and these so-called anion resins can replace anions. It follows that a combination of the acidic and basic resins or a cation and an anion resin can completely eliminate the mineral content of water by first allowing the cation-exchange resin in the form of a free acid to react with the salt and subsequently reacting the effluent with an anion exchanger.

Once the resins become saturated with minerals, they can be regenerated chemically and used over again as often as required. The process works most expediently where the concentration of a mineral matter is low, but the scavenging is so complete that the method has found favour not only in producing a so-called demineralized distilled water but in numerous industrial processes where the removal of ionic impurities is not possible by distillation. Ion-exchange resins have been used to remove mineral impurities from pharmaceutical preparations, dyestuffs, sugar, syrups, enzyme preparations, emulsions and glycols and formaldehyde. Other industrial uses include the recovery of valuable metals and various other inorganic and organic materials from industrial wastes. The resins have also been employed as catalysts in chemical reactions, particularly in the inversion of sugar.

2. *Resins for the Treatment of Paper.*—Another resinous ion which has attracted attention is the cationic melamine-formaldehyde resin. Unlike the ion-exchange resins, the cationic melamine resin is initially dispersible in water solution. The large ion is attracted toward and adheres to the cellulose fibre. It can be incorporated into paper by adding—as an acidic dispersion to a paper-pulp suspension and after migration to the paper fibre, the resin becomes insoluble and infusible during the drying of the paper stock. The resulting product is characterized by superior fold resistance and by a nonlignifying behaviour when dry, and when wet it does not disintegrate as does untreated paper. Water-dispersible urea resins with ionic properties have been developed and can be added to paper stock in a similar manner. Certain of these resins are anionic, i.e., they contain sulphonic acid groups and are flocculated on the fibres through the use of aluminum sulphate while others are cationic and need no flocculation agent.

RESISTANCE, MEASUREMENT OF: see INSTRUMENTS, ELECTRICAL.

RESONANCE, a term used in physics and related fields denoting a prolongation or increase of sound because of sympathetic vibration of some body capable of moving in the proper period. An illustration of resonance is seen when two heavy pendulums of the same period are mounted upon a wooden frame which yields slightly to their motion and one pendulum is set vibrating. In a few minutes it will be seen that the second pendulum is acquiring vibratory motion through the support. Its motion gradually increases until the two are swinging with equal amplitude but with a phase difference of a quarter period. The second pendulum continues to lag behind the first, gradually absorbing its energy until the first is brought to rest, after which the phenomenon is repeated in the reverse order. (See PHYSICS, ARTICLES ON.) The counterpart of this phenomenon is applied to electricity (*q.v.*). See ELECTRIC WAVES and articles related to radio.

RESONANCE, THEORY OF, in chemistry, is an extension of the theory of valence (*q.v.*), which contributed greatly to the understanding of the structure of molecules and the structural interpretation of the chemical and physical properties of substances.

The concept of resonance has been applied in chemistry in the elucidation of the nature of the covalent bond, of the partial

ionic character of bonds and of other aspects of valence. Its most important chemical applications have been to aromatic molecules, molecules containing conjugated systems of double bonds, hydrocarbon free radicals, and other molecules to which no satisfactory single structure in terms of single bonds, double bonds and triple bonds can be assigned.

For many molecules it is possible to formulate valence-bond structures which are so reasonable and which account so satisfactorily for the properties of the substances that they are generally accepted and are used as the basis for chemical reasoning. Examples of such molecules are:

It is sometimes found, however, that a choice cannot be made between two or more conceivable structures which are expected to be about equally stable and of which no one accounts in a completely satisfactory way for the properties of the substance. The concept of quantum-mechanical resonance provided the solution to this problem; namely, the actual normal state of such a molecule can be described as corresponding not to any one of the alternative reasonable structures but rather to a combination of them, their individual contributions being determined by their nature and stability. The molecule is then said to resonate among the several valence-bond structures or to have a structure which is a resonance hybrid of these structures. The molecule is stabilized by this resonance, its energy being less than the energy which would be expected for any one of the structures among which it resonates. This stabilization is characteristic of the phenomenon of quantum-mechanical resonance, which was discovered by Werner Heisenberg in 1926 (see below). The physical and chemical properties of the substance and the configuration of the molecule are determined by the nature of the resonating structures; these properties are, however, not the properties averaged for the resonating structures but are instead the averaged properties as influenced also by the effects of resonance and in particular by the additional stability resulting from the resonance energy.

The aromatic substance benzene provides not only an illuminating but also the most important example of the application of the concept of the resonance of molecules among two or more valence-bond structures. The formulation of the structure of benzene as a six-membered ring of carbon atoms with attached hydrogen atoms was made by F. A. Kekulé in 1865. To make the structure compatible with the quadrivalence of carbon he introduced alternating single and double bonds in the ring, and later, in 1872, in order to account for the nonobservance of isomeric orthodisubstituted benzenes (differing in having a single bond or a double bond between the substituted carbon atoms), he introduced the idea of an oscillation between two structures:

The Kekulé structure for benzene is unsatisfactory in that the substance does not show the properties of unsaturation to be expected for a molecule containing double bonds; and, after a period during which the centric structure of H. E. Armstrong and Adolf von Baeyer, the diagonal structure of A. Claus and the structure of J. Thiele based on his theory of partial valence were proposed, an important advance was made in the years following 1920 in the theory of intermediate stages proposed by F. Arndt and the theory of mesomerism developed by Sir Robert Robinson, C. K. Ingold and other English and U.S. chemists. The suggestion of these investigators, induced from the facts of chemistry, was that the true state of a molecule may be intermediate between those represented by several different valence-bond structures. Complete clarification of the structure of benzene was then provided in 1931 through the application of the theory of resonance and the consideration of the effect of resonance energy. According to the quantum-mechanical discussion of the structure of benzene, the normal state of this molecule can be represented as a hybrid of the two Kekulé

structures  and  and three diagonal structures of the form  (the para bond in these structures being

a weak bond, almost equivalent to a free valence on each of the para carbon atoms) and other structures which make smaller contributions. The configuration of the molecule should be a suitable average of those configurations corresponding to the individual structures. Because of the resonance the six carbon-carbon bonds are equivalent, and because of the stereochemical properties of a double bond the molecule as a whole is planar; hence the benzene molecule is predicted to be a planar hexagonal molecule, in agreement with observations made by the electron diffraction, X-ray diffraction and spectroscopic methods. Moreover, each carbon-carbon bond should be intermediate in length between a single carbon-carbon bond and a double carbon-carbon bond, the lengths of which, in molecules represented by a single valence-bond structure, are 1.54 Å and 1.33 Å, respectively. The observed value in benzene, 1.39 Å, is compatible with this prediction. Moreover, the benzene molecule is predicted from the quantum-mechanical considerations to be stabilized by resonance energy to the extent of about 40 kg.cal. per mole, relative to the value expected for one of the Kekulé structures. The amount of resonance stabilization can be estimated experimentally by measurement of the heat of combustion or heat of hydrogenation of benzene and related substances. For example, the heat of hydrogenation of cyclohexene is 28.6 kg.cal. per mole; if each of the three double bonds in benzene were the same as the double bond in cyclohexene, the heat of hydrogenation of benzene would be 85.8 kg.cal. per mole, whereas in fact the observed value is 49.8, indicating that the benzene molecule is stabilized relative to a Kekulé structure by the amount of energy 36 kg.cal. per mole, in approximate agreement with the quantum-mechanical prediction. The characteristic chemical stability and non-reactivity shown by benzene, relative to simpler unsaturated substances, may be attributed to this stabilization by resonance. It is possible, moreover, by the detailed consideration of the resonating structures to explain in a reasonably satisfactory way the other striking chemical properties of benzene, such as the influence of one substituent in determining the position of attachment of further substituents to the ring.

The structures of polynuclear aromatic hydrocarbons are similar. Naphthalene, for example, can be described as resonating among the three structures ,  and 

with small contributions from other structures analogous to the *para*-bonded structures of benzene, and the resonance energy of naphthalene is found to be about 75 kg.cal. per mole.

The stabilization of the aromatic heterocyclic molecules such as thiophen results from resonance of the most important structure

with structures such as

The resonance energy for thiophen is about 30 kg.cal. per mole.

The characteristic properties of substances which contain conjugated systems of double bonds can be readily accounted for by the

theory of resonance. A molecule such as biphenyl, ,

is stabilized not only by Kekulé resonance but also by the resonance energy of conjugation, resulting from the contribu-

tions of the somewhat less stable structures of type .

For biphenyl, phenylethylene and butadiene the resonance energy of conjugation is about five kg.cal. per mole. There are two stereochemical effects of this conjugation: the carbon-carbon distance for the single bond involved in the conjugated system is decreased from the single-bond value, 1.54 Å, to about 1.48 Å, as the result of the contribution of the conjugated structures with a double bond in this position; and the double-bond character of this bond also finds expression in the tendency to hold the adjacent bonds in the planar configuration. These molecules are observed to be planar or nearly planar, except when planarity is prevented by the arrangement of valence bonds or by steric effects, in which case the properties of the substance show that there is interference with the conjugation.

The phenomenon of resonance can be invoked in the discussion of the colour of dyes and other organic substances. The normal state of the cation of malachite green, for example, involves resonance among all structures of the sort shown below, in which the positive charge is located on different atoms within the molecule:

The excited states of the molecule are similar resonating states involving these structures. The absorption of light by the molecule, with its transition from the normal state to an excited state, occurs with great ease; the quantum-mechanical molecule can be compared with a classical oscillator in which a positive charge is resonating through a large amplitude, from one nitrogen atom across to the other, and from this comparison it can be predicted that the molecule should show intense absorption of light of suitable wave lengths.

Resonance also provides an explanation of the properties of many inorganic substances. For example, the carbon-monoxide molecule is a far more stable molecule than would be expected

from the apparent bivalence of carbon, and there was formerly discussion as to whether its structure should be written as :C=O: , containing a double covalent bond, or as $\text{:C}\equiv\text{O:}$, similar to the nitrogen molecule. The molecule can be assigned a hybrid structure based upon these structures, and its stability can be attributed to resonance stabilization. For carbon dioxide the structure :O=C=O: was for many years accepted without question; later, however, evidence of interatomic distances and other properties showed that this structure is in resonance with the two structures $\text{:O}\equiv\text{C}-\text{O:}$ and $\text{:O:}-\text{C}\equiv\text{O:}$. Nitric oxide, which is surprisingly stable for a molecule containing an odd number of electrons, can be described as achieving this stability through resonance between the structures $\text{:N}\equiv\text{O:}$ and $\text{:N}=\text{O:}$, and may be said to have a double bond plus a three-electron bond between its two atoms. The nitrate ion, NO_3^- , resonates among the three structures

making each of the nitrogen-oxygen bonds a hybrid between a single bond and a double bond.

The general rules regarding the resonance of a molecule among alternative valence-bond structures are the following: Equivalent structures contribute equally to the normal state of the resonating molecule. The more stable structures in general make larger contributions to the normal state, and less stable structures make smaller contributions. The electronic state of the resonating molecule applies to a definite configuration of the atomic nuclei, accordingly the energy values of the individual structures to be considered in connection with the foregoing statements are those calculated for the nuclear configuration of the actual state of the molecule and not for nuclear configurations which would be the most stable for the individual structures. The strain involved in this change in configuration in some cases makes structures unimportant which otherwise might be important. All of the structures which contribute to a resonance hybrid structure must have the same number of unpaired electrons; significant resonance does not occur, for example, between a structure with no unpaired electrons (singlet state) and a structure with two unpaired electrons (triplet state).

The basis of the theory of resonance is the fundamental principle of quantum mechanics that the wave function representing a stationary state of a system can be expressed as a sum of wave functions which correspond to hypothetical structures for the system, and that, in particular, the wave function representing the normal state of a system is that sum which leads to a minimum calculated energy of the system. The concept of resonance was introduced into quantum mechanics by Werner Heisenberg in an illuminating discussion of the stationary states of the helium atom (*Z. f. Physik*, vol. 38, p. 411; vol. 39, p. 499 [1926]). Heisenberg discussed certain excited states of this two-electron atom in terms of structures in which one electron occupies an inner orbit, close to the helium nucleus, and the second electron occupies an outer orbit; and he showed that an actual stationary state can be represented by a wave function obtained by adding to or subtracting from the wave function for this structure another wave function, representing the structure in which the second electron occupies the inner orbit and the first electron the outer orbit. On the basis of analogy with the classical system of resonating coupled harmonic oscillators, he assigned the name quantum-mechanical resonance to this concept (see *ATOMS; QUANTUM MECHANICS; SPECTROSCOPY*).

The special usefulness of the harmonic oscillator in the interpretation of quantum mechanics results from the fact that when this system is treated by the methods of classical mechanics and the old quantum theory, with the number $\frac{1}{2}$ added to the integral values of the quantum number, many of the calculated properties of the system are the same as those given by quantum

mechanics. The simplest system illustrating resonance consists of two equivalent harmonic oscillators with a weak Hooke's-law coupling between them. The potential energy for this system may be represented by the expression $2\pi^2 m \nu_0^2 x_1^2 + 2\pi^2 m \nu_0^2 x_2^2 + 4\pi^2 m \lambda x_1 x_2$, and the kinetic energy by $\frac{1}{2} m \dot{x}_1^2 + \frac{1}{2} m \dot{x}_2^2$, where m is the mass of each oscillator, x_1 and x_2 are the displacements of the oscillators from their positions of rest, ν_0 is the characteristic frequency of oscillation of each oscillator when there is no coupling ($\lambda = 0$), and λ is a parameter determining the strength of the coupling. The classical equations of motion for this system can be solved in terms of the normal co-ordinates $\xi = \frac{1}{\sqrt{2}}(x_1 + x_2)$ and $\eta = \frac{1}{\sqrt{2}}(x_1 - x_2)$. Each of these normal co-ordinates varies harmonically with the time, t , the integrated equations of motion being

$$\xi = \xi_0 \cos(2\pi\sqrt{\nu_0^2 + \lambda} t + \delta_\xi)$$

$$\text{and } \eta = \eta_0 \cos(2\pi\sqrt{\nu_0^2 - \lambda} t + \delta_\eta)$$

in which ξ_0 , η_0 , δ_ξ and δ_η are the constants of integration. It is seen that the characteristic frequencies for ξ and η , $\sqrt{\nu_0^2 + \lambda}$ and $\sqrt{\nu_0^2 - \lambda}$ respectively, differ from ν_0 . The co-ordinates x_1 and x_2 are then given by the equations

$$x_1 = \frac{\xi_0}{\sqrt{2}} \cos(2\pi\sqrt{\nu_0^2 + \lambda} t + \delta_\xi) + \frac{\eta_0}{\sqrt{2}} \cos(2\pi\sqrt{\nu_0^2 - \lambda} t + \delta_\eta)$$

and

$$x_2 = \frac{\xi_0}{\sqrt{2}} \cos(2\pi\sqrt{\nu_0^2 + \lambda} t + \delta_\xi) - \frac{\eta_0}{\sqrt{2}} \cos(2\pi\sqrt{\nu_0^2 - \lambda} t + \delta_\eta).$$

If η_0 is zero, the two oscillators carry out, exactly together in phase, a simple harmonic motion with amplitude $\frac{\xi_0}{\sqrt{2}}$ and frequency $\sqrt{\nu_0^2 + \lambda}$; and if ξ_0 is zero, they carry out, with phase difference π , a similar harmonic motion with amplitude $\frac{\eta_0}{\sqrt{2}}$ and frequency $\sqrt{\nu_0^2 - \lambda}$; but if neither η_0 nor ξ_0 vanishes, each of the oscillators vibrates in a complex way, the amplitude changing slowly from $\xi_0 + \eta_0$ to $|\xi_0 - \eta_0|$. This is the phenomenon described as classical resonance.

The rules of the old quantum theory with zero-point energy lead to the value $(n_\xi + \frac{1}{2}) h\sqrt{\nu_0^2 + \lambda} + (n_\eta + \frac{1}{2}) h\sqrt{\nu_0^2 - \lambda}$ for the energy of this system, and to the equations

$$\xi_0 = \{(n_\xi + \frac{1}{2}) h / 2\pi m \sqrt{\nu_0^2 + \lambda}\}^{\frac{1}{2}}$$

$$\text{and } \eta_0 = \{(n_\eta + \frac{1}{2}) h / 2\pi m \sqrt{\nu_0^2 - \lambda}\}^{\frac{1}{2}}$$

for the amplitudes. Each of the quantum numbers n_ξ and n_η can assume the values 0, 1, 2, . . . Since neither ξ_0 nor η_0 can vanish, even when the quantum number is zero, the oscillators show the phenomenon of classical resonance in every quantized state.

The stationary states of a harmonic oscillator in quantum mechanics are described by wave functions $\psi_0(x)$, $\psi_1(x)$, $\psi_2(x)$, . . . $\psi_n(x)$, . . . corresponding to the energy values $(n + \frac{1}{2}) h\nu_0$, with integral values for the quantum number n . The wave functions $\psi_n(x)$ are the successive Hermite orthogonal functions. The system of two equivalent coupled harmonic oscillators (with the same frequency) can be treated rigorously by use of the co-ordinates ξ and η , and the correct wave functions for the system are $\psi_{n_\xi}(x_1, x_2) \psi_{n_\eta}(x_1, x_2)$, the energy values being the same as for the old quantum theory, as given above. In this discussion of the system there is no need to mention resonance. However, the system may also be treated by a perturbation method, based on the wave functions $\psi_{n_\xi}(x_1) \psi_{n_\eta}(x_2)$ for the unperturbed system, with no coupling between the oscillators. For the normal state of the system, with $n' = n'' = 0$, there is only one wave function. There are, however, two independent wave functions, $\psi_0(x_1) \psi_1(x_2)$ and $\psi_1(x_1) \psi_0(x_2)$, for the next energy level; these functions correspond to states in which one oscillator has small energy, $\frac{1}{2} h\nu_0$, and the other has larger energy, $\frac{3}{2} h\nu_0$. It is found on treating the system of coupled oscillators that these functions are not satisfactory approximations to the correct wave functions represent-

ing the two slightly different energy levels of the system, but that their normalized sum and difference, $\frac{1}{\sqrt{2}}\psi_0(x_1)\psi_1(x_2) + \psi_1(x_1)\psi_0(x_2)$ and $\frac{1}{\sqrt{2}}\psi_0(x_1)\psi_1(x_2) - \psi_1(x_1)\psi_0(x_2)$, are satisfactory; the first wave function, symmetrical in the two co-ordinates x_1 and x_2 , represents the more stable of the two states, and the second, antisymmetrical in x_1 and x_2 (changing sign when x_1 and x_2 are interchanged), represents the less stable state. Each of these states is a hybrid of the two structures represented by $\psi_0(x_1)\psi_1(x_2)$ and $\psi_1(x_1)\psi_0(x_2)$, and, from analogy with the classical system, it has become customary to describe these hybrid states as resonance hybrids. This description is applied also to other quantum-mechanical systems which are conveniently discussed by a similar perturbation method, even though there is no close classical analogue for them.

The arbitrary nature of quantum-mechanical resonance is evident from the foregoing paragraphs. The system of coupled harmonic oscillators can be treated rigorously without mentioning resonance. It is for convenience, resulting from knowledge of the unperturbed wave functions, that these functions are used in the perturbation treatment. Quantum-mechanical resonance is not a property of a system, but of a system in relation to structures which are assumed as the basis for its discussion. In chemistry the theory of resonance is used primarily as an aid in discussing the structure and properties of complex molecules in terms of simple molecules. Simple structures similar to those which have been assigned to simple molecules are assumed as the basis for the discussion of complex molecules; and often when no one of the simple structures is satisfactory, a resonance hybrid can be formulated which represents the complex molecule in a satisfying and useful way.

The arbitrariness mentioned above is not characteristic of the theory of resonance in chemistry, but is shared by it with other branches of structural theory. It is recognized now that the structures of molecules may be correctly described by the quantum-mechanical wave functions pertaining to their normal states, and that the structural formulas assigned by chemists are symbols for the wave functions. For nearly a century chemists have written the simple valence-bond formulas H—H for molecular hydrogen, Cl—Cl for molecular chlorine and H—Cl for hydrogen chloride. The dash in the formulas H—H and Cl—Cl is a symbol for wave functions describing the normal states of these diatomic molecules formed of identical atoms. The normal state of the hydrogen chloride molecule is, of course, correctly described by its wave function, and this wave function is not rigorously related to the wave functions of the hydrogen molecule and the chlorine molecule. Nevertheless, chemists have found it convenient to assign the structural formula H—Cl to the molecule with use of a dash like that used in the formulas H—H and Cl—Cl, and to describe the hydrogen chloride molecule, like the hydrogen molecule and the chlorine molecule, as involving a single valence bond. Thus the valence-bond structural theory, which has been of great value in the development of chemistry, is an arbitrary approximate representation of the wave functions that alone correctly represent the molecules. It is conceivable that a system of symbols much different from the valence-bond dashes could be developed that would correspond just as well to the wave functions, but in fact a satisfactory alternative system of this sort has not been discovered, and chemists continue to use the valence-bond theory.

The theory of resonance in chemistry has been subjected to criticism because of its arbitrariness. The critics may not have recognized that, as mentioned above, the same criticism applies to the whole of structural theory. A structural formula for a nonresonating molecule such as ethane is a rough description of the wave function in terms of wave functions involving first a hydrogen nucleus, a carbon nucleus and a pair of electrons, and second two carbon nuclei (each with its inner shell of K electrons) and a pair of electrons. In the same way the structural formula for the resonating molecule benzene is a rough description of the wave function of benzene as a sum of valence-bond wave functions similar to the one assigned to ethane; the two Kekulé struc-

tures and other structures that are hybridized in the resonance representation of the benzene molecule do not correspond separately to states of the benzene molecule, but are symbols that, taken together, provide a rough description of the wave function of the molecule in its normal state.

The theory of resonance has been found to be of value in chemistry in the discussion not only of the configuration of molecules, internuclear distances, electric dipole moments, force constants of bonds and similar molecular-structural properties, but also of thermodynamic stability (as of aromatic substances, conjugated systems, free radicals), strengths of acids and bases, existence of tautomers, and chemical properties in general.

RESONANCE POTENTIALS. We are brought to the consideration of resonance potentials, which are also called critical potentials or excitation potentials, by the consideration of the passage of an electron through a gas. We must first premise that the energy, and consequently the velocity, of an electron is usually expressed in volts, a velocity of so many volts meaning the velocity which an electron would acquire in moving *freely* through a potential difference of that number of volts. It has been established by the experiments of J. Franck and G. Hertz that electrons of small energy, i.e., with velocities of a few volts only, behave like minute gas atoms when they strike a gaseous atom. The impact follows the laws of the impact between two perfectly elastic spheres, the electron bouncing off with practically no loss of velocity, since the mass of the gas atom is relatively so great. When we are considering the passage of electrons through inert gases, metallic vapours of small electron affinity, and certain other gases, it is found, however, that, as the velocity of the electrons is raised, a certain critical value is reached; for all velocities greater than this critical velocity the electron loses a definite amount of energy in the collision, or makes what is known as an inelastic impact. The kinetic energy so lost goes temporarily to increase the internal energy of the atom, and ultimately appears in some other form. If the velocity of the electron be further increased the loss of energy at impact remains the same until a step is reached when another sudden loss of energy takes place on impact, this time of greater magnitude. In general, as the potential which accelerates the electron is increased a series of values will be found, at each of which a different type of inelastic collision with the gaseous atom first takes place. These particular values are the resonance potentials characteristic of the gas in question; they vary in magnitude from gas to gas. Finally, a potential can be found which gives the electron sufficient energy for it to be able to ionize the gas atom which it strikes, that is, displace an electron from it. This potential is the *ionization potential* of the gas.

Theoretical Importance of Resonance Potentials.—The resonance potentials have assumed great importance in modern physics from the direct confirmation which they give of the most fundamental assumption of Bohr's theory of atomic structure. (See ATOM; QUANTUM MECHANICS.) On this theory an atom can exist in a series of stable states—or stationary states, as they are called—to each of which pertains a given energy, but cannot exist in any state of energy intermediate between these. We can get a picture of these states by assuming that the electrons of the atomic structures have certain preferential orbits, to each one of which corresponds a certain energy of the atom (see ATOM), but this picture is not indispensable for our present purpose. To transform the atom from its normal state, of energy E , to a stationary state of greater energy E' , clearly demands a certain input of energy: when the atom returns from this excited state to its normal state—either in one step or more steps—the energy is given out again, in general in the form of radiation (in general, because it is possible for the energy to appear as kinetic energy of another particle), the frequency of the radiation being given by $h\nu = E' - E$ where h is Planck's constant, ν the frequency. We should therefore expect that if an electron strikes an atom, and its energy is less than that required to raise the atom to the first stationary state above the normal, it will be unable to communicate any-

thing to the internal energy of the atom, and will spring off elastically. If, however, the energy E_0 of the electron in question equals or exceeds $E_1 - E_0$, where E_1 is the energy of the first stationary state, it can raise the atom to that stationary state, and will proceed after the collision with diminished energy $E_0 - (E_1 - E_0)$. We neglect the kinetic energy communicated to the atom as a whole, since, on account of the great mass of the atom, this is negligible. Similarly, if the energy of the electron exceeds $E_2 - E_0$, when E_2 is the energy of the second stationary state, the electron can raise the atom to that state, experiencing itself a correspondingly greater loss of energy. In the first case the atom, on returning to its normal state, should emit the first spectral line of a series, in the second case the second line, of higher frequency, and higher critical potentials should be able to excite lines of still higher frequency. The resonance potentials therefore provide a double experimental check on Bohr's hypothesis. In the first place we can, by electrical methods, measure the velocity of the electron before and after impact with the gas atom, observe at what potentials the abrupt losses of velocity take place, and compare these potentials with those to be anticipated from the known values of $h\nu$ for the appropriate lines of the spectrum of the atom. In the second place we can observe the radiations from the gas which attend the passage of electrons of different velocities, and find out at what potentials the different lines first appear—i.e., we can carry out the so-called step-by-step excitation of spectra, and measure the excitation potentials. Both methods lead to brilliant quantitative confirmation of Bohr's hypothesis of stationary states, and of the quantum theory of spectral series. The electrons lose energy in steps, at the stages to be anticipated from the theory, and the spectral lines appear in turn at the potentials calculated.

Experimental Methods.—The pioneer worker on the subject was Lenard, who in 1902, long before Bohr's theory was put forward, showed that an electron must possess a minimum energy before it can produce ionisation in a gas. He released the electrons from a hot wire, and directed them by means of a magnetic field, through a hole in a glass plate, into a gas. The electrons then struck the gas, and produced ionisation. The amount of ionisation was measured by means of an electrometer. The results showed that the ionisation was not continuous, but occurred in steps, at certain critical potentials. These critical potentials were found to be the same as those calculated from Bohr's theory for the excitation of the spectral lines of the gas. This was a brilliant confirmation of Bohr's theory, and showed that the electrons must possess a minimum energy before they can produce ionisation in a gas.

However, as pointed out by Bohr and van der Bijl, a change in the current from R does not necessarily indicate ionisation in the gas between E and R, for if the electron impact is not sufficiently energetic to make the atoms struck lose an electron, but merely makes them emit radiation, then this radiation will act photoelectrically on the plate R, causing it to lose electrons. As far as current effects go, loss of electrons by R or gain of positive ions by R come to the same thing. Lenard's original method has therefore been modified in various ways, to enable a distinction to be made between a resonance potential and an ionisation potential. It is also usual nowadays to produce the electrons by means of a hot wire (see THERMIONICS) instead of photoelectrically. Davis and Goucher introduced a second gauze E' (fig. 2) and arranged the potentials as follows: a potential V_R , greater than the accelerating potential V_A , acts so as to stop the electrons reaching R, while a small potential V_1 , which can be reversed, is maintained between E' and R. When E' is negative to R photoelectric electrons cannot escape from R, when E' is positive to R they can, so that the photoelectric effect of radiation on R can be detected at once. Reversal of the direction of the

small field between E' and R has, however, little effect on the passage of positive ions to R, because these are accelerated by a comparatively large potential fall, and have sufficient energy to overcome the opposing field. In this way radiation potential and ionisation potential can be clearly distinguished. Lenard's method has also been modified by Franck and Hertz in a famous series of experiments which dealt especially with the resonance potentials of mercury vapour. This vapour has yielded particularly clear confirmation of Bohr's theory. There are, for instance, resonance potentials at 4.9 volts and 6.7 volts. The wave-lengths which correspond, on the quantum theory of spectra, to these potentials can be calculated from the fundamental equation

$$\text{energy} = eV = \frac{hc}{\lambda} = h\nu$$

when e is the electronic charge, V the potential in volts, h is Planck's constant, c the velocity of light, λ the wave length. To 4.9 volts corresponds a wave-length of 2520 Å.U., to 6.7 volts a wave-length of 1844 Å.U., which agree, within the experimental error of these measurements, with 2536 Å.U. and 1849 Å.U., the wave-lengths of the two strong lines of the mercury spectrum to be anticipated on the theory.

G. Hertz has more recently worked out some very delicate methods of measuring both resonance and ionisation potentials. One of the methods detects, by a skilful disposition of the gauges, the abrupt loss of velocity of electrons which takes place when the accelerating potential reaches a critical value: this method therefore measures radiation potentials. The other method depends upon an annulment of the so-called space charge, which surrounds a hot wire, by the positive ions produced when, but not before, the accelerated electrons have sufficient energy: this method clearly detects ionisation potentials.

A different type of experiment, that which relies on the excited radiation for a sign that the resonance potential has been reached, is represented by the work of Foote, Meggers, and Mohler. They use the disposition represented in fig. 3. The electrons are produced, as usual, by a hot wire, here of hairpin shape, and accelerated by the field between the wire and the grid, constituted by a close spiral coil. The comparatively large cylinder which surrounds the grid is kept at the same potential as the grid. The region in which the electrons are accelerated is narrow, so that there is little chance of an impact which would prevent an electron attaining its full velocity: the region between the grid and plate is wide, so as to give plenty of opportunity for impacts to produce radiation. The accelerating potential is varied, and the values at which individual spectral lines appear carefully noted. The study of resonance potentials in this way was initiated by Franck and Hertz, who observed the potential which was just sufficient to excite the well-known mercury line of wave-length 2536 Å.U. They were followed by McLennan and his students, who showed that either one or two lines or the whole series could be excited, according to the potential. Since then other workers, notably Newman, have succeeded

FIG. 1.—LENARD'S METHOD OF INVESTIGATING IONISATION POTENTIALS

in producing certain spectral series line by line, each new line first appearing at the potential indicated by Bohr's theory.

All these experiments clearly show that energy can be communicated to atoms in definite amounts only, and that the communication of a definite amount of energy to an atom is followed by the emission of a spectral line or lines, the wave-length of these lines being connected with the energy communicated exactly as indicated by the quantum theory of spectra. It should be added that not only can one electron be completely removed from an atom at the ionisation potential, but that a higher potential can be measured which suffices to remove two electrons, and so excite the so-called spark spectrum. (See SPECTROSCOPY.)

Applications of the Theory of Resonance Potentials.—The established fact that a perfectly definite energy is needed to excite any given spectral line, or to separate an electron from an atom and so ionise it, has found wide application. The energy with which one atom strikes another at room temperatures is far below that which corresponds to the first resonance potential of any gas, and so we can expect no luminosity of gases at ordinary temperatures. In a flame the temperature is already sufficient for an appreciable fraction of the atoms to collide with sufficient energy to excite spectral lines. If metal atoms are introduced into a flame, the lines which are detected at the lowest temperatures are the lines with the lowest excitation potentials, and as the temperature of the flame is raised more and more lines appear, in accordance with the theory, the increased energy of the atomic impacts corresponding to the increased energy of electron impact which we get as we raise the potential. Again, elements with spectra of low resonance potentials show in the flame more lines at a given temperature than those with high resonance potentials. More striking still are applications of the conception of ionisation and resonance potentials to astrophysical problems. By considering the ionisation of an atom as a chemical problem, in which the ionisation potential takes the place of the heat of dissociation, Saha has worked out the percentage ionisation to be expected under different conditions of temperatures and pressure, and applied his result to the spectrum of the sun, with very interesting results. He has especially considered the ionisation of calcium atoms in the sun's atmosphere, and explained many peculiarities of the apparent distribution of the element. This work has been much extended, especially by R. H. Fowler and E. A. Milne. (See STAR.)

RESORCINOL, also called resorcin, is metadihydroxybenzene, $C_6H_4(OH)_2$. It was first obtained in 1864 by H. Hlasiwetz and L. Barth by the potash fusion of certain natural resins (galbanum, asafoetida, etc.). It crystallizes in colourless rhombic prisms or plates, which dissolve readily in water, alcohol or ether and sparingly in benzene. It melts at $110^\circ C$. and boils at $276.5^\circ C$. at 759.7 mm., or $178^\circ C$. at 16 mm.; its density is 1.287 at $15^\circ C$. It has a sweet taste, and its aqueous solution gives a deep-violet coloration with ferric chloride.

Resorcinol is an important commercial product and is manufactured in large quantities from benzene. The general procedure consists in sulphonating benzene with fuming sulphuric acid to benzene metadisulphonic acid and fusing the sodium salt of this acid with caustic soda at a relatively high temperature. The crude resorcinol is extracted, preferably with ether, from an aqueous solution of the fusion mass neutralized with a mineral acid. Technical resorcinol is obtained by boiling off the solvent and vacuum distilling the crude resorcinol. It is purified by sublimation or by recrystallization from a strong aqueous solution.

Resorcinol is used in the manufacture of resins, plastics, adhesives, dyes, explosives, cosmetics, pharmaceuticals and as an intermediate in the synthesis of many other organic compounds.

By the second half of the 20th century, the biggest use for resorcinol was in making adhesive resins and plastics. These resorcinol-formaldehyde-type resins are cold setting and are used with a catalyst or hardener. They will bond wood and many other ma-

terials at contact pressure. Although these resins had been known for a long time, the technique of controlling them was not solved until the early 1940s. During World War II they played an important part in marine, aircraft and other types of construction.

Resorcinol is a component in some azo dyes. It couples readily with diazo compounds. Two moles of diazo compound can be coupled in succession with one mole of resorcinol. It is also condensed with phthalic anhydride to produce fluorescein, and through this the various dyes of the eosin and rhodamine types. By condensing with β -nitrosodimethylaniline hydrochloride (on the fibre) it yields an oxazine dye. The dinitroso derivative of resorcinol is fast green or Alsace green.

Resorcinol possesses some antiseptic properties and is used in solutions and ointments for chronic skin diseases such as psoriasis and eczema and as a urinary antiseptic. In large doses resorcinol causes giddiness, deafness, salivation, sweating and convulsions. When applied externally to large surfaces it has proved dangerous and even fatal. Appreciable quantities of resorcinol are used in making hexylresorcinol, an antiseptic of germicidal value; beta-methyl-umbelliferone, a sun-screening agent; and lead styphnate, the lead salt of trinitroresorcinol, which is a powerful detonator used in the manufacture of sporting ammunition.

RESPIGI, OTTORINO (1879-1936), Italian composer, was born at Bologna on July 9, 1879, and studied at the Liceo of Bologna, at St. Petersburg (Leningrad), under Rimsky-Korsakov, and in Berlin under Max Bruch. In 1913 he was made professor at the Royal Liceo di S. Cecilia in Rome, and in 1933 director. The operas *Semirama* (1910) and *La bella addormentata* (1922) were followed by the successful *Belfagg* (1923), which reflects in the eclecticism of its style the cosmopolitan character of the composer's training. His orchestral music includes the symphonic poems *Aretusa* (1911), *Le fontane di Roma* (1916) and *Phi di Roma* (1924); in the way of chamber music he has written a sonata for violin and pianoforte, and two string quartets, while a "concerto Gregoriana" for violin and orchestra may also be mentioned.

RESPIRATION. The conception of life is so closely bound up with that of respiration that the very word "expiration" has come to connote the extinction of life, and "inspiration" its elevation to a super-human level. Respiration is a process common to all forms of animal life, the reason for which is that the chemical basis of life is essentially an oxidation of tissue. Rightly, we speak of the "flame" of life, for in the body, as in the fire, material is all the while being consumed, with concurrent consumption of oxygen, and the production of carbon dioxide. Respiration consists essentially in the transport of oxygen from the air to the place where the oxygen is used up by the body, and the transport of carbon dioxide from the place where it is produced to the external air. Many animals, of course, live in water; indeed, life presumably began in that medium. But even for them the ultimate source of oxygen is the atmosphere; from it the water acquires fresh stocks of oxygen as the animals which inhabit it use up the gas. The oxygen in water is for the most part in solution, not in bubbles; but in the sea the constant breaking of the waves has a most potent effect in oxygenating the surface layers of the water.

In the most primitive forms of life respiration is very simple. In the amoeba, which is little more than a minute particle of jelly, the respiratory process is carried on in this way: The amoeba lives in water, from the water oxygen soaks into the body of this animalcule, where it is always being used up, and because it is always being so used the potential of oxygen inside the amoeba is always less than the potential of oxygen in the water outside. The oxygen, therefore, by a simple process of diffusion, is ever tending to migrate from the place of higher to that of lower

potential, *i.e.*, from the water to the interior of the amoeba, so a constant stream of gas is maintained. So also with the carbon dioxide; it is produced in the amoeba, from the interior of which it diffuses out, through the surface into the surrounding water.

In the higher forms of life, there is no different principle involved, so far as is known, from that of the amoeba. The apparatus for effecting respiration becomes more complicated, but the actual process is the same, namely, the *diffusion* of gas, oxygen or carbon dioxide from the place of higher to the place of lower potential.

THE SUPPLY OF BLOOD TO THE LUNG

The necessity for some definite system of transport arises partly from the greater size of animals as compared with the amoeba, and partly from the greater intensity of their oxidative processes. The inhabitants of an island a mile square would need no special transport system for the carriage of their fish, but the population of a continent does, and not only the mere machinery for moving the fish but all the accessory apparatus of cold storage and the rest for moving it in good condition. Moreover, if the continent be inhabited by persons with an insatiable craving for fish the capacity of the transport system must be correspondingly increased.

In the more lowly organized aquatic animals the system of transport is as follows: A circulation is maintained throughout the animal of fluid which differs little from seawater. At some point, known as the gill, this circulation comes very near to the surface, being only separated from the seawater by the wall of the vessel in which it is coursing. That wall is no thicker than the body of the amoeba, and so the gases, oxygen and carbon dioxide, have no difficulty in diffusing into and out of the circulating fluid. The amount of gas which can be dealt with depends principally on the extent of the surface of circulating fluid that can be exposed at any one time to the water. Therefore, for the purpose of creating the maximal surface, the gills of some creatures take on curious and feathery forms. Such are those of the lobster, which may be seen by breaking away the shell at the side. Indeed, the surface is so great that the water around the gill would be completely denuded of oxygen were there not a special mechanism for ensuring a constant circulation of fresh water, carrying a continuous supply of oxygen-charged water over the surface of the gill feathers.

The gill system of the lobster exhibits the principles on which the respiratory systems of almost all the higher animals are based, *i.e.*, the exposure of a large surface of fluid which circulates in the animal (the blood) to a corresponding large surface of either air or water which is constantly being replenished. The oxygen-containing medium and the circulating blood are not in actual contact, but are separated from one another by a membrane through which the oxygen (and carbon dioxide) must diffuse. One section of the animal kingdom has attempted a respiratory system on different lines, namely, the insects. In them the air is piped all over the interior body to, or almost to, the actual functioning cells. There is no intermediary circulating fluid. The whole tissues of the insects are therefore permeated by an elaborate system of tubes, the tracheae, with walls stiff enough to prevent their collapsing. The tracheal tubes are often extremely narrow in bore. This system has grave limitations. The rate at which gases can diffuse along very fine tubes is very slow, and sufficient oxygen can only penetrate, therefore, for a short length. No portion of the insect, therefore, can be far removed from the external air, and for that reason all insects are small; the largest development of which they seem capable is that of the dragon fly, which has a relatively long but extremely attenuated body. Developmentally the insects are side-tracked.

To return to the normal line of development, the principles of respiration are simply portrayed in such an air breathing animal as the newt (fig. 1a). Imagine a grape with a tubular stalk and with air inside the skin instead of fruit, and you have something like the lung of the newt. In the substance of the wall the blood circulates, a large surface being exposed in a close network of capillaries to the air in the lung, which air is intermittently forced

in and out of the lung by swallowing movements on the part of the newt, the stalk of the lung (or trachea) being an outgrowth of the gullet.

Leaving for the moment the consideration of the circulating fluid, we may follow two other lines of development: (1) the mechanism for increasing the amount of surface of fluid exposed to air and (2) the mechanism for perfecting the ventilation of the lung.

Mechanism for Increasing Exposed Surface of Fluid.—

In the lung of the frog a much larger surface of blood can be exposed than in that of the newt, for the inner surface of the lung is thrown up into ridges, called *septa*. These again give rise to secondary and even tertiary *septa*, as is shown in fig. 1b. All these *septa* are richly supplied with blood capillaries.

FIG. 1.—SCHEMATIC REPRESENTATION OF SECTIONS THROUGH LUNGS (A) Lung of the newt with no septa, (B) lung of frog showing primary, secondary and tertiary septa, (C) Infundibulum of human lung showing primary septa.
